We have, therefore, in dealing with this question, to separate with care the Roman workings and the so-called Jews' workings, from the truly early British excavations. The evidences of sheltering earth-works appear to me to be exceedingly strong in favour of the existence of the most ancient of British mines. One of the most remarkable of these is the Bolster, in St. Agnes, which may be traced from Polbreen to Chapel Porth; and there are many indications of its having been continued in the other direction to Trevaunance, thus inclosing the whole of St. Agnes Beacon, upon and around which tin has been, and is, abundant. Similar inclosures are to be yet traced in St. Just and many other places, and either within or very near these we may generally find that every lode has been worked—by simply clearing it out as far as the primitive miner could follow it—by following every string, however small in size it may have been, and indeed by employing the rudest methods of the untaught mind. Many of the rock castles, and many of the "rounds" could have been constructed for no other purpose than to protect the stores of tin which had been gathered in the neighbourhood of them. I believe we may by a little cautious investigation separate the ancient British workings from those which were directed by the Romans, or those which were carried out by the Jews at a later period. This investigation I desire to open—it is full of interest.

The general tendency of all Cornish antiquarians and historians has been to make St. Michael's Mount the Iktis of Diodorus, from the circumstance that it agrees, at the present time, precisely with the description of the ancient historian. Diodorus speaks not of an island, but of islands, and to these the Britons conveyed their tin. Secrecy as to the localities from which this then precious metal was obtained, was to be preserved. The Tyrian traders were kept on the coast; they do not appear to have been admitted to the mainland. This circumstance explains the construction of such works as the Bolster, the hill castles, the rounds, or, at least, of some of them, and many other arrangements made for secrecy and safety. The means for conveying the heavy ore being necessarily limited, there can be but little doubt that the nearest secure place of shipment would be selected, and perhaps in every case the traders were confined to the islands near the coast. It is not improbable that tin may have been *carried* to the Scilly Islands, seeing that there has ever been a shadowy tradition pointing to them as the Cassiterides. But St. Michael's Mount still preserves the character given to the Iktis by Diodorus, and it was no doubt one of the islands named by the historian, and to it, in all probability, was taken for sale and shipment all the tin obtained in the western district. Seeking for the other islands, two especially present themselves. These are St. Nicholas' Island in Plymouth Sound, and St. George's or Looe Island. At the present time these islands are constantly surrounded by water, but an examination of the Admiralty charts will show that over the "bridge" which connects St. Nicholas Island with Mount Edgcumbe there is, even in the centre opening at low water, only a few feet (I believe only three) of water, while all the other parts are left dry. The rocks which run out from Hannafore Point, by the Midmain Rock, in like manner connect Looe Island with the main, there being but a few feet of water above them at low tides.

We have the evidence of the submarine forest in Millendreth Bay, near Looe; of the raised beach at Redding Point under Mount Edgcumbe; of the submarine forest in the Mount's Bay, and numerous raised beaches around the coast, to support the hypothesis of a change in the relative level of land and water. This is not, however, required to support the view that at one time the two islands named were left with a passage dry from them to the shore. The disintegrating action of the waves, beating on either side of such a neck as that which we supposed to have existed, and the abrasive power of tidal currents, would be quite sufficient to produce the separation, without any raising or lowering of the land. But for the protecting influence of the mass of greenstone, running out from Marazion, called the Hogus, and that which is afforded, also, to some extent, by the elvan dyke forming the Long Rock, especially the other portion called the Bayman, and the interpenetration of the clay slate around the island, by granite and quartz veins, there is no doubt but St. Michael's Mount would long since have been in the position of St. Nicholas and Looe Islands. The proposition which I endeavour to support is, that St. Michael's Mount, St. George's or Looe Island, and St. Nicholas' Island, were three of the islands included under the description given by Diodorus. I think there are others, especially on the north coast of Cornwall, which might be included. That the tin produced by the ancient Cornish people over the western district found its way to St. Michael's Mount; that the extensive district around St. Austell sought for a shipping port at Looe Island; and that the tin obtained from the Calstock and Callington districts, and that collected from the wide range of Dartmoor, was taken to St. Nicholas' Island, in Plymouth Sound.

Sir George Cornewall Lewis has recently been endeavouring to revive the claims of the Isle of Wight. However that lovely spot came to be regarded as the probable Iktis is strange, seeing that it does not agree with any one of the conditions required. Certainly, we have one island which yet preserves all the characters required, and at least two others which may have been in the condition of islands when the tide was flowing, but having passages to the main land at low water; and these will be found, I believe, to be the islands of the ancient historian.

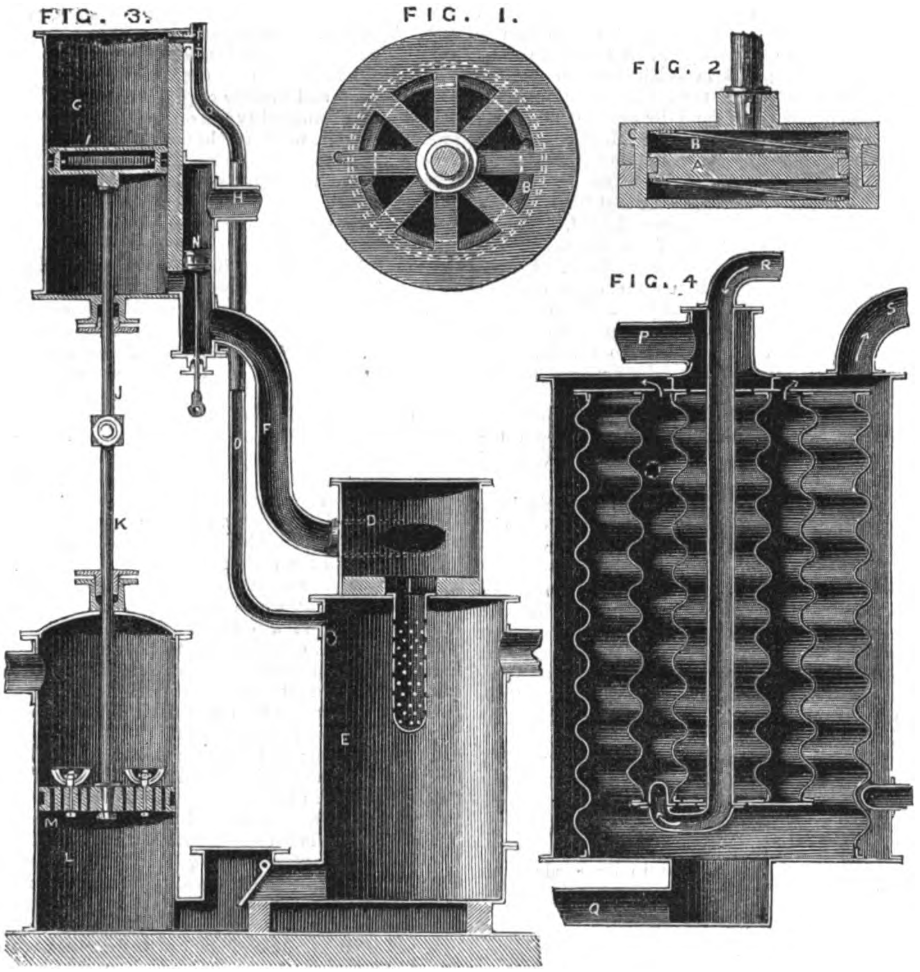
While reading the above paper, Dr. Barham said that there was another island which had not been mentioned by Mr. Hunt, and with which Mr. Hingeston was better acquainted than himself. It was situated near the mouth of the Yealm, and if one of those islands alluded to by Diodorus, it would be convenient for tin from the district beyond Ivybridge in Devon. He had proposed to read some notes on this subject, which would have had reference to the views advocated with much learning by Sir Cornewall Lewis, which tended to the conclusion that the Phœnicians did not themselves come to Britain, but that the trade in tin carried on by them with this and other countries, was through the intervention of the people living on the coast of Gaul. It appeared to him, on examining the argument of Sir Cornewall Lewis, that this opinion was not properly supported; and it seemed to him that it would be interesting, in reference to our ethnology and the character of the early civilisation of the Cornish, to show that the probabilities were all on the other side. He considered that Sir C. Lewis had employed arguments which were of great weight, as tending to throw a doubt that the Phœnicians navigated round the shores of Africa; but these arguments did not bear on the probability of that people having had intercourse with this country, carrying on a coasting trade with Gallicia in Spain, where there were workings in tin, and on the coast of France to some extent, and afterwards coming over to the coast of Britain. The only other people who were navigators at a very early though later period were the inhabitants of the coast of Gaul, but there were not sufficient grounds for knowing whether they traded in tin. The Phœnicians, however, were known to have traded in tin, and taking that fact alone, the probability was more in favour of the impression that the Phœnicians carried on the trade in tin in their own vessels than that they employed Gaulish vessels. That, however, would be one of the points to be considered. There were various others which he should very much like to see taken up by persons competent to do so, in order that they might be brought before the Association in a manner worthy of the importance of the subject. Another branch of the argument was the linguistic branch, which would be elucidated by the terms used by miners in the Celtic countries where mining was carried on. It would be a very strong argument in favour of Phœnician intercourse with this country, if it should be found that the mining terms used by the miners in Cornwall were distinct from those of Wales and other members of the Celtic race. The Phœnician language was little else than pure Hebrew, and it would be a powerful argument if it should be found that Cornish mining terms had a Hebrew and Semitic origin, while those employed in the principality and other Celtic countries producing no tin, were of Celtic origin. Then there were a variety of little things in which Cornwall differed from other Celtic countries which ought to be investigated. There was the article of Cornish cream, which very strangely was confined to the limits of old Danmonia. It was a curious fact, that in the country which was occupied by the ancient Phœnicians, that peculiar cream had been found—on Mount Carmel a traveller was served at a monastery with a dish of Cornish cream. There were also a considerable number of usages, such as the observance of Midsummer Day, and other things, to be considered. Owing to the manner in which his time had been occupied in carrying out the arrangements in connection with the meeting of the Association, he had been unable to follow up the investigation of the subject; but he had thought it right to bring it under their notice. He then called attention to two or three articles which were of considerable interest as having some connection with the early tin trade of the county. The first was a small symbolical image of what was called a bull, but which might just as well be called a lion. It was found while digging the foundations of a school-room at St. Just, and Mr. Birch, of the British Museum, to whom it had been submitted, said that it was the god Apis. It was marked by a crescent on the flank, and similar markings had been used in the time of the Roman emperor Hadrian; and it was considered to be the most distinct article of Oriental manufacture that had been found in the county. The second article was a block of what was called "Jews'-house tin." Mr. Hunt had alluded to the trade in tin carried on by the Jews in the time of King John, but there was doubt as to their being employed in smelting tin in early times. Similar blocks of tin had been found in many of the Jews' houses in the county, but why they had been left he could not tell. He then referred to a leaden image which had been found on Redmoor, not far from Mr. Robartes's, and which had been called a Hebrew image on no better evidence than of its having four Hebrew letters on it. It had been sent for inspection to the Archæological Institute, but Mr. Albert Way returned it the other day, saying they could make nothing of it.

M. SCHAU'S APPARATUS FOR AVOIDING SCALE IN BOILERS.

THE apparatus of M. Schau consists of a cylinder closed on top and connected with the boiler by a short tube. Into this cylinder the feed water is thrown in a shower, so that the heat of the steam brings it instantaneously to the boiling temperature before it reaches the boiler. This rise of temperature precipitates the solid matters which are deposited in the cylinder, while the water in a purified state goes to the boiler. An Austrian locomotive provided with this apparatus ran over 5,500 miles (8,880 kilom.); during which about 45lbs. of a soft material like soap was deposited in the cylinder, while the boiler was kept perfectly clean. This result is the more remarkable, since at the beginning of the experiment it was coated, to a thickness of $\frac{3}{16}$ths of an inch, with a solid crust, which completely disappeared during the experiment.

M. Engerth, State-Counsellor, who presided at the meeting of Austrian Engineers, to which the above was communicated, remarked that it was probably his experiments on locomotives which suggested to M. Schau the first idea of his simple and ingenious apparatus. It is known, in fact, that when the feed-water returns to the tender after being strongly heated, there is formed in that reservoir a considerable deposit, whilst the boiler itself is comparatively free.—*Zeitschrift der Osterreichischen Ingenieur-Vereins.*

RIPPINGILLE'S IMPROVEMENTS IN STEAM ENGINES AND PUMPS.



This invention, just patented by Mr. F. A. Rippingille, of Staple Hill, near Bristol, is applicable to those constructions of steam engines wherein the injection water in its way to the condenser is caused to enter a cylinder, and to act on a piston working therein, so that the power obtained thereby may be rendered available in the working of the steam engine. And the invention consists—1. In applying an elastic piston in the injection cylinder or engine to prevent concussion at the termination of the stroke, and also during the covering of the port by the valve.

2. In applying a chamber or vessel to the condenser in such manner that the injection water from the injection cylinder or engine shall be first received into such chamber or vessel, and then be by it delivered continuously in numerous streams or jets into the condenser, the chamber or vessel being of such capacity, and so arranged, as to retain sufficient water to keep up a supply of water to the condenser during one half stroke of the piston in the injecting cylinder.

3. In applying apparatus for refrigerating the condensed water from a steam engine in combination with an injecting cylinder or engine.

4. In a combined arrangement of air pump and injection cylinder, or engine (by which the air is withdrawn from, and injection water is supplied to, the condenser) with a water pump for withdrawing the condensing water, and condensed steam from the condenser.

5. In a mode of constructing steam engine condensers.

Fig. 1 of the above engravings is an upper view; and fig. 2 a section of a hollow piston, in which a circular disc or inner piston A is placed. The outer piston C and the inner piston A are suitably packed to render them air and watertight. Springs B B are placed above and below the inner piston to keep it in position. By means of the springs the piston is rendered elastic, in such manner that it may yield in place of causing a shock at the termination of the stroke, and when the port or outlet is closed; fig. 3 shows a vertical section of a condenser having a regulating vessel D applied thereto, by which a continued supply of injection water is kept up to the condenser E, there being a perforated tube descending therefrom into the interior of the condenser. The injection water is supplied into the regulating vessel D, which is capable of containing a quantity of water sufficient to continue the injection during the time that no water is being passed from the injection cylinder. Plates are placed in the bottom of the vessel D in order that the water in that vessel may be prevented rotating therein, which it would otherwise be liable to do by reason of the rush of water from the injection cylinder or engine through the supply pipe F. It is preferred to employ the condensed water obtained from the steam engine as injection water after it has been cooled or refrigerated, which however is not new, but according to the present invention apparatus for refrigerating the condensed water is applied between the cistern or vessel into which the water from the condenser is received, and the injection cylinder or engine by which it is supplied to the vessel D, and consequently to the condenser as injection water. The arrangement of the apparatus employed for this purpose is as follows:—The outlet of the pump which removes the water from the condenser is connected with a refrigerating apparatus, and the inlet pipe of the injection cylinder or engine is connected with the refrigerating apparatus, so that the water from the condenser is first refrigerated, and it is then received into the injection cylinder, and from it the water passes into the vessel D to the condenser. The refrigerating apparatus consists of a cylindrical vessel, around which cold water circulates, also an annular cylindrical vessel within the same, having cold water circulating through it. The injection water from the condenser is delivered within the annular cylinder, and passes to the bottom, and then under the annular cylinder; it then traverses the outer side of the annular cylinder to the top of the main cylinder, and, finally, traverses the inner surface of the main cylinder, for which purpose a plate of iron is fixed around the main cylinder, within about one inch of the same, to keep the injection water in close contact with the cooled surface of the main cylinder.

The engravings also show an arrangement or combination of air, an injection pump or cylinder, and a water pump for removing water from the condenser. The duty heretofore performed by the air pump is thus separated, by which the water pump used for removing the injection water, and the water of condensation from the condenser, may be less than an air pump usually employed for a like sized steam engine wherein the air pump performs the two duties of an air pump and a water pump for removing the air and the water from the condenser; G is the injection cylinder or engine; the water for injection is admitted on one side of the piston, and the air from the condenser is admitted on the other side of the cylinder, and as the injection water which enters the cylinder G through the supply pipe H is subject to the pressure of the atmosphere, it will by pressing on the piston I in the cylinder G aid the working of the steam engine with which it is used; J is the piston rod of the cylinder or engine; G and K is the piston or pump rod of the water pump L. Motion is given to the two piston rods J K by the steam engine with which the cylinders G and K are in combination. In the fig. the parts are shown in the positions they assume when the pistons I and M are descending, and the valve N of the cylinder G has closed the passage for the water into the cylinder G, and opened the passage for the injection water to pass from the cylinder G into the chamber or vessel D, whilst the air from the condenser passes from the condenser through the pipe O into the upper end of the cylinder G.

Fig. 4 shows a vertical section of a condenser, in which corrugated sheet copper or other metal is used, bent or formed into annular vessels one within the other. The steam is admitted at the inlet pipe P, and the water of condensation and the air are removed at Q, cold water enters at R, and passes off at S, after being circulated through the annular vessels, as indicated by the arrows.

STEAM-BOILER EXPLOSIONS.

The following is an abstract of the chief engineer's monthly report, which was presented at the last ordinary monthly meeting of the executive committee of the Association for the Prevention of Steam Boiler Explosions, held September 2:—

"During the past month the ordinary visits of inspection have been made, and 8 boilers tested by hydraulic pressure, the following defects being discovered in the boilers examined:—Fracture, 3 (2 dangerous); corrosion, 26 (6 dangerous); safety-valves out of order, 14; water gauges ditto, 10; pressure gauges ditto, 13; feed apparatus ditto, 4; blow-off cocks ditto, 37 (1 dangerous); fusible plugs ditto, 6; furnaces out of shape, 3; blistered plates, 2. Total, 118 (9 dangerous). Boilers without glass water gauges, 4; without pressure gauges, 16; without blow-off cocks, 11; without back pressure valves, 31.

"The principal cases of dangerous injury which have arisen this month have been due to corrosion, the continued recurrence of which shows the importance of having all boilers examined, not 'externally' only, but also 'internally and thoroughly.'

"Another explosion has occurred during the last month to the class of plain cylindrical egg-ended boilers, fired externally. The boiler in question, which was not under the ins ection of this association, was one of a series of six connected together, in the midst of which it had worked, being the fourth from one end, and the third from the other. Its length was 30ft., its diameter 5ft., the thickness of its plates $\frac{3}{8}$ths of an inch, and its work-

ing pressure 50lbs. The rent, as is usual in these cases, occurred at one of the transverse seams over the fire, but the developement of the line of fracture was somewhat peculiar. In ordinary cases these boilers, on explosion, separate at one of the ring seams into two distinct halves, which fly in opposite directions; but, in the present instance, the first belt of plates was completely severed from the remainder of the boiler and flattened out, having rent through the line of rivets at each of its four edges, while the egg-end had become entirely disengaged from it, and, in addition, was torn into two parts. The remainder of the boiler, which was by far the greater portion, being about 24ft. long, had flown to a distance of from eighty to ninety yards, and the chimney, which was reduced to a heap of ruins, had either been swept down by it in its course, or blown down by the impact of the steam.

"There was no evidence of there having been either deficiency of water or excess of pressure; while each boiler in the series was fitted with two lever safety valves of three inches' diameter, a glass water gauge, and a back-pressure feed valve. The exploded boiler was about four years old, and had been repaired seven months since, at the part immediately over the furnace, by the introduction of two new plates.

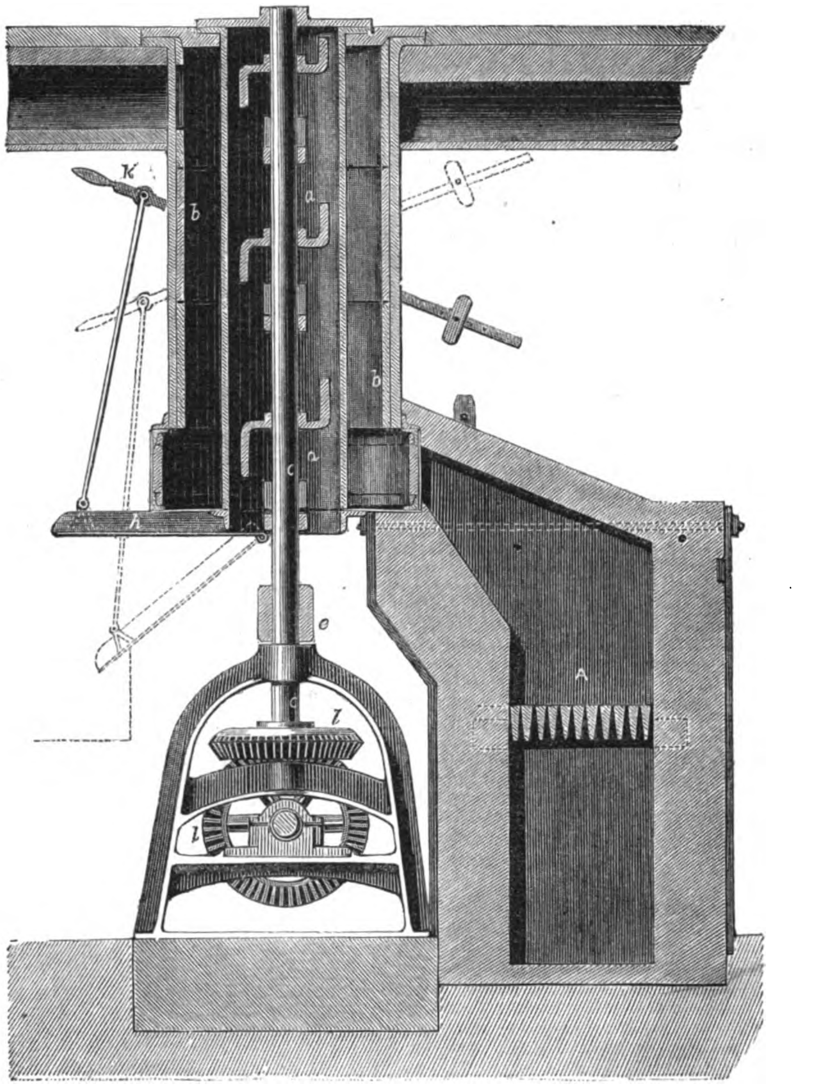
"It will be observed that the above explosion is another instance of the liability of these externally fired boilers to rend at the transverse seams over the fire. The combined duty thrown upon these seams is so great, that there is more uncertainty with these boilers than with those of the internally-fired double-furnace class in ordinary use in Lancashire. All the points in the latter can be so entirely mastered that they may be thoroughly relied on, and if well made, and in sound condition, can, with proper care in working, be guaranteed as safe for a period of twelve months from the time of examination. Not so, however, with the externally-fired boiler, in which the shell has to endure the entire disruptive strain combined with the direct impingement of the flame. In the internally-fired boiler these two duties are divided; the shell, which bears the tensile strain, being guarded from the intense action of the fire, which the furnace tubes are adapted to bear, from their small diameter and facility for strengthening, either by flanged seams, hoops or otherwise; while the deposit, which to a great extent rolls off the furnace crowns, and falls harmlessly to the bottom of the boiler in one case, deposits itself immediately on the fire in the other. Thus the seams of rivets in externally fired boilers have to contend with the combined influence of tensile strain, the direct action of the fire, and too frequently with an accumulation of incrustation tending to overheating; and even where this does not form a positive coat, it may yet suffice so to thicken the water that the steam lifts it from the surface of the plate, when over-heating unavoidably ensues; added to which sudden draughts of cold air, on opening the furnace doors, cool the outer laps of the plate at the seams, which thus become subjected to the constant alternations of expansion and contraction.

"Under these circumstances it is not surprising that the seams of rivets in under-fired boilers should frequently be found suddenly to give way, for which the surest remedy will prove to be the substitution of internally-fired boilers in their place. Where, however, those externally fired are still adopted, it is earnestly recommended, in the first place, that good materials and workmanship should be secured; in the second, that every means should be adopted for the prevention of incrustation; and, in the third, that the seams of rivets should be constantly and narrowly watched, so as to detect the first signs of weakness, which should be immediately repaired.

"Ready examination is facilitated by setting these boilers, as some of our members are doing, with a single direct flash flue, in which are a series of bridges, one behind the other, for keeping the flame in contact with the boiler; an entrance being made beneath the furnace bars, as well as a small archway through the back bridges, to allow of a communication throughout.

"L. E. FLETCHER, Chief Engineer."

WOOD'S IMPROVEMENTS IN THE MANUFACTURE OF ARTIFICAL FUEL.



MR. T. H. WOOD, of Blackweir, Glamorgan, has patented an "Improvement in apparatus employed in the manufacture of artificial fuel."

The invention consists in constructing and arranging a cylinder or tube, and parts connected therewith, in which cylinder dry and hot coal and pitch are finally intimately mixed or amalgamated together during their manufacture into artificial fuel, in such manner that the said cylinder or tube may be maintained from top to bottom at a red heat, and that the material may be passed through the said cylinder, and be thoroughly mixed and amalgamated therein without choking or clogging.

Within an outer casing, lined with fire clay or other material, to prevent loss of heat by radiation, a vertical iron cylinder or tube is placed, leaving a space between the casing and the tube. This space forms a spiral flue communicating at bottom with a furnace, and having its outlet near the top and from the side of the apparatus. Upon a shaft made to rotate inside the cylinder, arms are fixed, the ends of each arm being turned or bent up or down at right angles, or nearly so, with the arm. These bent ends approach nearly to, but do not touch, the cylinder, and act as scrapers to keep the cylinder clean, and prevent it being clogged. The cylinder is fed at top, and the amalgamated material issues from the bottom into a shoot provided for its reception. The discharge of the material is regulated by the inclination of the shoot.

The above engraving is a longitudinal section of an apparatus constructed according to this invention. *a* is a vertical cylinder or tube; and *b* is the outer casing made to form a spiral flue, by which heat is conveyed round the cylinder *a* from a furnace A, opening into the said flue; *c* is a shaft passing through the cylinder, and supported at bottom in a shoe; *e* is a socket joint or coupling to allow of the shaft being removed when not in use, or of its being replaced by another, should circumstances require it. Arms are placed on the shaft with bent-up ends and turn-down ends, as shown. The dry and hot coal and pitch are fed in at the top of the apparatus, and escape from the lower part thereof, through an outlet; *h* is a flap or shoot, the outer end of which is connected by a chain or rod to a lever *k*, with a balance weight, so that the opening can be closed when the machine is first put into operation, and afterwards either partially opened as the state of the material operated upon may require; thus regulating the angle at which the flap is kept, and thereby the discharge of the amalgamated material; *l l* is the driving gear. For the purpose of facilitating the removal of the shaft and scrapers when required, a pulley chain and winch are fitted immediately over the shaft *c*.

A huge battery is in course of construction at Woolwich, to carry a number of 110-pounder Armstrong guns, for the purpose of experiments at sea. The floating battery Trusty, fitted with Capt. Coles's cupola, and destined for experiments with the 300-pounder Armstrong gun, to fire a 150-pounder cylinder, still remains in basin at Woolwich, under a protest of Captain Coles, as not having been fitted in accordance with his design, nor under his supervision,

ERICSSON'S MONITOR OF 1854.

We have received an illustrated circular from New York. It is headed "Ericsson's Monitor of 1854; America, not England, its Birth-place; Ericsson, not Coles, the Inventor of the Revolving Cupola." The circular gives a side elevation of the battery, and a transverse section of the centre of the revolving copula. It also gives an extract from a communication addressed from New York to the Emperor of the French, on Sept. 26, 1854. The receipt of this communication was at once acknowledged by his Majesty. The following are extracts:—

New System of Naval Attack.—The vessel to be composed entirely of iron. The midship section is triangular, with a broad hollow keel, loaded to balance the heavy upper works. The ends of the vessel are moderately sharp. The deck, made of plate iron, is curved both longitudinally and transversely with a spring of 5ft.; it is made to project 8ft. over the rudder and propeller. The entire deck is covered with a lining of sheet iron 3in. thick, with an opening in the centre 16ft. diameter. This opening is covered by a semi-globular turret of plate iron 6in. thick, revolving on a column and pivot by means of steam power and appropriate gear-work. The vessel is propelled by a powerful steam engine and screw propeller. Air for the combustion in the boilers, and for ventilation within the vessel, is supplied by a large self-acting centrifugal blower, the fresh air being drawn in through numerous small holes in the turret. The products of the combustion and impure air from the vessel is forced out through conductors leading to a cluster of small holes in the deck and turret. Surrounding objects are viewed through small holes at appropriate places. Reflecting telescopes, capable of being protruded or withdrawn at pleasure, also afford a distinct view of surrounding objects. The rudder stock passes through a water-tight stuffing box, so as to admit of the helm being worked within the vessel. Shot striking the deck are deflected, whilst shell exploding on it will prove harmless. Shot (of cast iron) striking the globular turret will crumble to pieces, or are deflected. This new system of naval attack will place an entire fleet of sailing ships, during calms and light winds, at the mercy of a single craft. "Boarding," as a means of defence, will be impracticable, since the turret guns, which turn like the spokes in a wheel, commanding every point of the compass at once, may keep off and destroy any number of boats by firing slugs and combustibles.

A fleet at anchor might be fired and put in a sinking condition before enabled to get under way.

Of what avail would be the "steam guard ships" if attacked on the new system? Alas for the "wooden walls" that formerly "ruled the waves!"

The long-range Lancaster gun would scarcely hit the revolving iron turret once in six hours, and then, six chances to one, its shot or shell would be deflected by the varying angles of the face of the impregnable globe. When ultimately struck at right angles the globe, which weighs upwards of forty tons, will be less affected by the shock than a heavy anvil by the blow of a light hammer; consequently, the shot would crumble to pieces, whilst the shell would strew the arched deck with harmless fragments.

During contest the revolving turret should be kept in motion, the port-holes being turned away from the opponent except at the moment of discharge, which, however, should be made during full rotation, as the lateral aim in close quarters requires but little precision.

Absurdity of Captain Coles' Claim.—Captain Coles states, in a letter to the *Times* of April 5, 1862, that his experience in the Baltic and Black Seas, in 1855, suggested to him the idea of building impregnable vessels, and that towards the latter part of the year he had "a rough model made by the carpenter of the Stromboli," and that he proposed to protect the guns by a stationary shield or cupola. Captain Coles, it appears, met with no encouragement from the Admiralty, and therefore consulted Mr. Brunel, the celebrated engineer, who warmly embraced the plan. "He did more," says Captain Coles, in his letter to the *Times*; "he assisted me in my calculations, and gave me the aid of his draughtsmen." Captain Coles further states that, notwithstanding official neglect, he persevered, and in March 1859, produced drawings of a "shield fitted with turn-tables." Lastly, in December 1860, Captain Coles published, in *Blackwood's Magazine*, drawings of his "gun-shield and revolving platform," the platform being turned by manual power only.

AN INDIAN COAL FIELD.

British India is far from being without its coal fields; indeed, we believe we are correct in saying that it possesses a large number, which are rich in this material. The fields of Karharbale, Sylbet, Assan, Palamo, Bandelkand, and Narbadda Valley, produce yearly a large supply of coal; but the largest and most important field is known as the Raniganj, or Burdwan, or Damuda field, which is known to yield the largest supply, and no region in India can compete with the Raniganj coal fields in the quantity obtained from its seams.

This field embraces an area of 500 square miles, and is thirty-nine miles by eighteen in its two greatest diameters. It appears, however, that a considerable proportion of this land is not entirely occupied by coal-beds, as they are restricted to two sub-divisions of the strata which are contained in the field. Those which alone contain coal seams are the Raniganj and Barakar, or Damudas series, which comprise together a thickness of about 7,000 feet of beds. Important and extensive collieries are worked in the Raniganj series, but the mines of the Barakar series are fewer and of less importance. It is said that the coal here, although it exists in enormous quantities, is in quality so variable, and the thickness of the seams so irregular, that mining operations are not carried on to a great extent. But even the profitableness of these extensive mines depend greatly on the extension of the explorations there. A line of railway will, however, do much to carry out this object. It is a singular fact, but worthy of being recorded, that for some time there were great doubts expressed as to the existence of coal in the Raniganj mines, owing to certain unreliable reports made by a committee some years ago. The Geological Surveyor to the East India Company, with great difficulty, endeavoured to dispel the unfavourable opinions; but, since that gentleman's death, coal seams have been worked in the very spot where it was so urgently contended there were none.

The extraordinary mineral properties of the coal fields to which we have alluded have made them very popular in India. They contain animal remains, and, it is said, abound in mollusca of the carboniferous age. In the course of a recent survey, a "bone bed" was found on the banks of the Damuda, which abounded with skeletons of extinct animals, and these discoveries have awakened a great deal of surprise and attention among our scientific brethren in India. By the recent report on the Geological Structure and Relations of the Raniganj Coal Field, we find that they comprise a vast number of valuable fossils of enormous size.

We might add, that so large is the supply of coal found in the Raniganj seams, that the out-turn is only limited by the small number of labourers engaged in the working of them.

WHEATSTONE AND THE UNIVERSAL PRIVATE TELEGRAPH COMPANY *versus* WILDE.

This important patent case, which was partly heard before Mr. Baron Wilde and a special jury, and afterwards referred for arbitration to Mr. Lush, Q.C., after a protracted hearing of twelve days, has at length terminated in favour of the defendant. The plaintiffs' invention, upon which the action was brought, was for an improvement in the transmitting instrument of a magneto-electric dial telegraph, which consisted of a method of keeping the armature of the magneto-electric machine in continuous motion, while finger-keys regulated the passage of the currents into the telegraphic circuit. The defendant, by the peculiar construction of his magneto-electric machine, was enabled to stop the armature every time a finger-key was depressed.

The armature was made to revolve by means of a pulley driven by a band, the tension of which was so regulated that when the mechanism of the transmitting instrument (including the armature) was stopped by the depression of a finger-key, the band slipped upon the pulley, and no more currents were produced; but on releasing the finger-key the motion was immediately taken up, and currents were again generated and allowed to pass into the circuit.

The plaintiffs contended that continuous motion of the motive power was equivalent to a continuous motion of the armature. It was, however, clearly shown that this was not so, for the defendant's armature required to be made very light, so that it might be stopped with facility; while, on the other hand, the plaintiffs' armature being kept in continuous motion, its size and weight were of no consequence.

The arbitrator, therefore, decided that a stopping armature could be no infringement of an armature in continuous motion, and that the bill of complaint in the Court of Chancery should be dismissed, and the costs thereof, and the reference and award should be paid by the plaintiffs.

ELECTRIC ENGRAVING MACHINE.

This machine, shown in Class VII. of the International Exhibition, is used for engraving the cylinders of copper or brass, employed in the printing of woven fabrics and paper hangings.

Its great distinctive feature — apart from its general mechanical arrangements — is in the application of voltaic electricity in communicating certain necessary movements, to important and delicate portions of the apparatus.

The cylinder to be engraved is first coated on its outer surface with a thin film of varnish, sufficiently resistant to the continuous action of the strongest acids. The requisite number of copies of the original design are then traced or scratched simultaneously by a series of diamond points which are arranged on the machine, parallel with the axis of the cylinder. Each diamond point is in correspondence with a small temporary magnet, and the entire series is so arranged *en rapport* with the original design, which had been previously etched on a metal cylinder filled in with a non-conducting substance (this cylinder being made to revolve in contact with a tracing point), that when the electric current passes, intermittent currents are established, whereby the diamonds are withdrawn from their work at the proper intervals. The metallic surface is thereby exposed in certain parts, and a bath of nitric or other acid being afterwards used to etch or deepen the engraved portion, the operation is completed.

Amongst other special advantages said to be derived from the use of this apparatus, the facility with which engravings may be enlarged or diminished to any necessary extent from the same original, is not the least important.

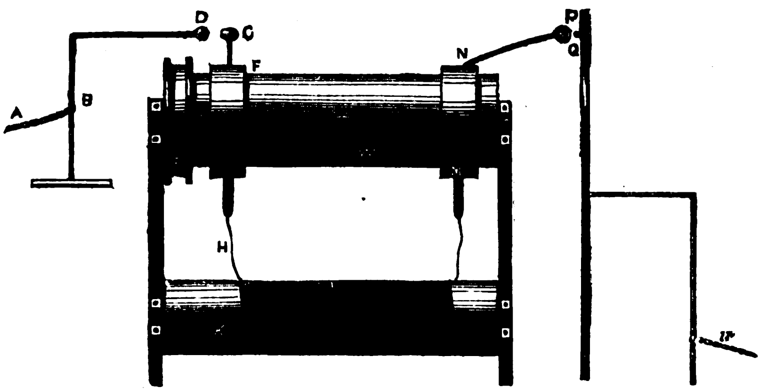
THE STRAIGHT LINE *VERSUS* THE WAVE LINE FOR VESSELS.

TO THE EDITOR OF "THE MECHANICS' MAGAZINE."

Sir,—In my letter to you on this subject, contained in the Mechanics' Magazine of the 22nd ult., I remarked that Mr. Cheverton seemed to me to turn his attention more to the water after it had been disturbed by the passage of the vessel than to the question at issue, viz. how to move the water so that the least power shall be expended in moving it. I see by his reply that he does not do so.

Referring to his letter in your journal of the 15th ult., I find his remarks to be as follow:—"In the passage of a vessel through the water there is an immense amount of motion among its particles, which, though occasioned thereby, is not due immediately to the propulsive action of the bow, and which does not enter as an element into the resistance encountered. The proximate causes thereof are the head of water raised in front and the depression produced at the stern. These give rise to currents and waves, the latter being propagated indefinitely."

In his reply to my letter, in which I spoke of the snow and ice accumulating against the piles in the



form of a wave-line cutwater, he says: "The destructive tendency of the current is to remove obstacles at any cost of power; nature is not called upon to economise; and so the ice, supposed to have at first a triangular shape (straight line bow?), is gradually destroyed just below the apex of the cutwater, where it is weak (where the resistance increases?), until it takes for that portion of it the form of least resistance corresponding to its own strength, and the velocity of the stream (wave line bow?), that is to say, it becomes a more acute triangle with sides not differing sensibly for some little distance from straight lines; but observe that this can take place (assuming the breadth of the cutwater is maintained) only with the necessary consequence of a more obtuse form being produced at a point farther down the stream (greatest breadth of ship?), and offering a greater resistance than the straight line would have done. As this result is gradual, a hollow curve line is generated with the salient angle at the haunch rubbed off."

I will accept this explanation of Mr. Cheverton's as a proof of the wave or hollow line, when properly applied, being superior to any other form for least resistance. I will take the current to represent the speed of the ship through the water; the power "to remove obstacles," as the wind or steam propelling that ship; and the "more obtuse form farther down the stream offering a greater resistance," as the beam of the ship or greatest immersed section of resistance, to be forced through the resisting fluid; and what more can be wanted by way of proof that we have the form of least resistance? As to his remarks on "variable velocities," "mean resistance," &c., and his regarding what has been advanced on behalf of the wave line to prove its superiority "as proof to just the contrary," I have nothing to say; one is free to believe or disbelieve as one chooses, or, more possibly, c cording to the limit of one's understanding; but what is required here is proof, not supposition; facts, not theory; the results of practical working, not deductions from theoretical notions of what should or should not be. The problem is that of moving a given resistance, or immersed section of hull, at a given velocity, with the least expenditure of power, and, consequently, with no more disturbance of the water in which it floats (or, in plain English, by causing no more water to move out of the way) than is required for the passage of the widest portion of the ship, and the question is, what form of line for the bow of the ship is best; is it the wave line, the convex line, or the straight line? I answer that practice proves the wave line to be the best, and what Mr. Cheverton must now do is to prove, from the results of practice, that the straight line is superior, or even equal.

Mr. Cheverton does not say whether he has read the works I named; I do not think he has, or he would certainly not advance the idea that there is any similarity between a fish totally submerged, and moving in a "homogeneous" element, and a ship floating on that element, exposed to other and external influence. "I take it that this is only an example of a wrong interpretation of phenomena," or, at least, of choosing as an illustration a case anything but applicable to the purpose.

I shall now, with Mr. Moy, "remain silent upon the subject" until Mr. Cheverton can bring forward proofs, and "something better than he has hitherto done," of the superiority of his straight-line bow for ships.

Apologising for again troubling you on the subject,

I am, sir, your obedient servant,

CHAS. F. T. YOUNG, C.E.

7 Duke St., Adelphi: London, Sept. 1, 1862.

NEW METHOD OF ASCERTAINING THE VELOCITY OF ELECTRICITY.

SIR,—The above is a nice subject of philosophical enquiry. I am not aware that what is called the velocity of electrical transmission has been satisfactorily determined. From a great many experiments which I have made, but which it would take too much of your space to detail here, I am inclined to believe that electrical transmission is instantaneous. In thinking upon this subject for some years, the following scheme occurred to me lately, by which, so far as I can see, the velocity of glass electricity may be determined, if anything less than 1,000,000, or any less number of miles per second, or any greater number of miles per second, by enlarging the extent and the expense of the apparatus. If it be true (as it appears to be, according to Faraday's experiments) that glass and voltaic electricity are the same (although it is with the greatest deference, from innumerable experiments I have made, I beg to dissent) than the velocity determined in respect of glass, electricity will apply in ordinary railway transmission. The above sketch will enable any intelligent person acquainted with the mere elements of electricity to understand what I mean.

Let B be a metallic stand connected with what is called the positive part of an electrical apparatus by means of the chain or other metallic communication A. C is a stud, terminated by the ball D; W is a cylinder of baked wood or any other non-conducting material, which can be put into any attainable rate of rotatory motion, by means of a belt circling the pulley E. The hoop F is affixed to the cylinder W, to which is attached the stud terminating in the knob G. A spring is supposed to press on the hoop F in electrical communication with an insulated wire H, wound round K, which wire may be of any length—the longer the better. The end M of this wire presses, by means of a spring, on the other hoop round W. To this hoop is attached a rod N, and a knob P, the knobs G and P being in the same straight line parallel to the axis of the cylinder W; so that when the knob is at the least striking distance from D, the knob P may be at the zero point Q on the circular disc. This disc is supposed to be graduated from the zero point at Q up to any number of equal parts—say a thousand—and fixed. It communicates with the negative part of the apparatus by means of a chain W, from the disc. Hence, when G is at the least striking distance, the electrical communications proceed from D G, thence along the wire round W, through the hoop to the disc opposite P, and from that, by means of the chain or wire W, to the negative part of the apparatus. Now, if the communication from D to Q is instantaneous, the spark or mark at Q will take place at the zero point of the disc. But suppose that the cylinder W makes 100 revolutions in a second, that the wire round K is 100 miles long, then, in the 100,000th part of a second, Q passes from the zero point of the disc to the division 1 on the same; in double the time to 2; and so on. These divisions may be determined by pasting paper soaked in a mixed solution of starch and iodide of potassium on the disc. Then, if any measurable interval is occupied in this transmission, the same is the time taken to pass through the wire round K; and thence the velocity of transmission may be determined.

A. ROY,

Government Examiner in Navigation,

Local Marine Board, Dundee.

August 21, 1862.

PROPOSED BRIDGE ACROSS THE HOOGHLY.

SIR,—I observe in your Magazine of last week that in an account of a proposed bridge over the Hooghly, near Calcutta, the span of the Niagara Suspension Bridge is stated as 281ft. This is probably a misprint. It is well known that the Niagara bridge has a clear span of 822ft., which is, I believe, at present the longest span for railway traffic yet constructed.

It should be noted, however, that the speed of all trains is restricted by special rule to five miles per hour in crossing, and it is doubtful whether the timber truss below the suspension chains would prevent for any length of time the occurrence of dangerous undulations during the rapid passage of heavy trains. I believe, from personal observation of the structure, that the fastenings would shake loose; but, at the same time, am inclined to think that at no distant date the suspension principle, with rigid chains and platforms, will be almost universally adopted for all large railway bridges. Various methods of stiffening such spans have been proposed, and the enquiry is one to which a greater degree of attention may be profitably directed than has hitherto been accorded to it.

I remain, your obedient servant,

A. ALEXANDER.

13 Gresham Street, London, E.C.: Sept. 8

MR. S. W. WORSSAM AND "THE ENGINEER."

SIR,—I beg to intrude upon your valuable columns, and trust through them you will grant me the opportunity of refuting the following assertion published by the editor of the *Engineer*, in his remarks upon a letter of mine inserted in that journal of the 5th inst., viz.:—"Mr. Worssam has written several letters on this subject which were of a tone altogether precluding their admission into our columns." This I emphatically deny. I have written but two letters, both of which have been inserted in that journal, one on Aug. 22, the other was sent by me on the 29th, but not inserted till the following week (the 5th inst.), the first paragraph only having been altered to suit the whim of the editor. Underneath is the original (being of a tone precluding it from the columns of the *Engineer*) for your perusal; the insertion of the paragraph so substituted will assure my friends I have written nothing so invidious as the editor would have them infer:—

"You are pleased to be facetious in your remarks upon my former letter. I should imagine you had crossed the Atlantic and caught the mania for perversion. You accuse me of assuming that in the article in question, you wrote from assumption rather than fact."

Yours, most respectfully,

S. W. WORSSAM.

Sept. 9, 1862.

Gossip.

Upwards of 300 tons of the forged $4\frac{1}{2}$in. armour-plates for casing the sides of the iron-clad frigate Royal Oak, 50, have been received at Chatham during the past few weeks from the Thames Iron Works, the Parkgate Foundry, and the other firms under contract to supply the Admiralty. The whole of these have been tested under the direction of the leading officials of the establishment, and each submitted to the annealing process in the factory erected for that purpose, in order to render the iron as tough as it is possible to make it. Although the operation of plating the Royal Oak has been suspended for the last fortnight, to enable the necessary arrangements to be made for her launch, the preparation of the plates is still carried on in the factory, where upwards of one hundred of the large slabs are now accumulated. Each plate before being affixed to the frigate's side costs, on the lowest estimate, 200*l.*, the contract price, at which they are supplied to the Admiralty, being 37*l.* per ton. The plates average a weight of 80cwt. each, which will give an original cost of 148*l.*, added to which there are the charges for annealing, bending, planing, boring, and otherwise preparing them, to accomplish which the most costly machinery has to be employed.

The *Cumberland Pacquet* informs us that during the week Mr. John Kennedy has been giving tests to the new screw which he has invented for the propulsion of vessels. The testings were made with an open boat, to which Mr. Kennedy had attached one of his screws, and he has had the gratification of finding that the screw possesses propelling and backing powers of great extent.

An invention of a novel nature has just been laid before the Board of Admiralty, which consists in two distinct and separate gunboats strongly united together, but having two separate bows and sterns, as well as keels. This novel description of ship is propelled by two screws, in addition to two of Gladstone's chain-paddles, on each side. The inventor states that such ships are perfectly manageable, and that a speed of twenty-four knots an hour will be attained by them! Among other advantages claimed by the inventor is the fact that they will be able to make better headway in rough weather, and that, should the engines of one be out of order, the other will be able to do the work of both, *pro tem.* The natives of the Sandwich Islands formerly used similar "twin sailing vessels." And it will be remembered by our readers that we inserted a letter from Captain Selwyn on the subject.

At the weekly meeting of the Mersey Docks and Harbour Board, last week, Mr. Lyster, the dock engineer, having taken into consideration the application of Messrs. Gibson & Kinder for extensive accommodation for the storage and manufacture of petroleum at Birkenhead, had prepared a most complete report on the subject, as well as plans of the proposed buildings which he suggested should be erected to the westward of the graving docks at Birkenhead. This report had not yet been fully considered by the works committee, but it had been sent out to several firms interested in the petroleum trade, with the view of ascertaining their opinion of the scheme. A letter in reply, the only one yet received, was read from Mr. A. S. Macrae, speaking in the highest terms of the engineer's plan as one which was calculated to work most satisfactorily both for the trade and the public. Mr. Lyster's plan will probably be fully considered at the next meeting of the works committee, and, it is believed, will afford the most complete accommodation for carrying on the trade upon a very extensive scale, and the cost of the works he estimates at about 37,830*l.* The Town Council have unanimously approved of this plan.

On Friday last, Mr. Glashier made another ascent from the yard of the gas-works at Wolverhampton, in Mr. Coxwell's balloon, for meteorological experiments, which are being conducted under the direction of the balloon committee of the British Association for the Promotion of Science. At twelve o'clock 60,000 cubic feet of gas, of a rarity that exceeded any that Mr. Proud, the skilful engineer to the gas company, had produced previously, having been pumped into the balloon, Mr. Glashier entered it with an array of meteorological-testing instruments of wondrous delicacy, and Mr. Coxwell having taken up his position, the aerial ship was loosed from her moorings, and floated away in the direction of Stourbridge.

Mr. John White, of West Cowes, has received orders to build a paddle-wheel steamer to realise a speed of eighteen miles an hour.

It is proposed to form a line of railway from Seabrook, in the vicinity of Hythe, Sandgate, and Shorncliffe camp, to the Beakesbourne station on the London, Chatham, and Dover Railway.

The Scotch pig-iron market during the past week has been less active, and the speculative demand, which was very eager during the month of August, has greatly diminished. A fortnight ago, the price was 56*s.* 9*d.*, and on the 5th of this month 55*s.* 6*d.* cash, with the appearance of soon touching somewhat lower figures. The shipping demand is rather sluggish, but home consumption is improving. Bar iron makers have seldom been busier than they are just now. Founders have also got better orders, and the trade, on the whole, is said to be in a more satisfactory state than it has been for many months. Exports last week were 12,255 tons, against 10,526 tons same week last year.

Mr. James Bruce, in a communication to us, says: "I find that among the numerous substitutes offered for cotton, none produces for colour, length, and fineness of fibre anything to equal the *Lichen plicatus* (or Hairy Tree). It is only necessary to dry it in an oven, to thresh it, and to sift it to obtain the fibre."

The third Conversazione of the Society of Arts will take place at the South Kensington Museum on the 8th of October.

The Emperor of the French went on Monday week to the Polygon of Vincennes to witness some experiments with the system of cartridges with compressed powder. A new invention called the "pendulum cannon," a new infantry musket, and a new system of breech-loading gun, invented by M. Chassepot, were tried before His Majesty, who appeared very much satisfied with the results.

"An Artizan" writes: "Palmam qui meruit ferat." The differential pulley-block (though by no means a new invention), being but little known, merited a description in your pages. It was the invention of, and the credit for its ingenuity belongs, however, to, a "Mr. Moore, of Bristol," and by his name, if any, should it therefore be called. It is fully described in Dr. Carpenter's "Mechanical Philosophy," London, 1843, pp. 282–3, and the author expresses his surprise "that this ingenious invention has not come into more general use."

A Munich letter states that the telegraphic cable made at Cologne for the purpose of communication between Landau and Bohrschäch across the Lake of Constance is quite finished, and will soon be submerged. It is 70,000ft. in length, and contains four wires.

A novel incident, says the Philadelphia *Ledger*, occurred on the Widow M'Clintock's Farm, Oil Creek, recently. That portion of the tubing of the Van Slyke well which runs into the receiving tanks from the well was removed, in order to make some repairs, leaving the conductor-pipe still in the well. Next morning the inhabitants of that region were startled by the sound of a gigantic steam whistle, and found that it proceeded from this well. The gas, forcing up through the pipe, had probably met with some obstruction, which caused it to perform in this way. The scream of this whistle was tremendous, and could be heard several miles.

The Portpatrick Railway, which is only 7½ miles right across the peninsula, has cost about 90,000*l.* The principal piece of masonwork is a viaduct of 14 arches, and from 90 to 100ft. high, crossing the Piltanton Burn, at a short distance from Colfin station. This station, which lies about half-way on the new railway, is the apex of the line, the road being from Stranraer up-hill, and from Colfin all down-hill. For half-a-mile below this place the incline is 1 in 240; then there is, for a short space, an incline of 1 in 64; and from Pinminnock down to Portpatrick it is 1 in 57; and on the beach thence down to the harbour, as steep as 1 in 35. There are also some heavy cuttings on the new line, the greatest of which is that half-a-mile above Portpatrick. This cutting is nearly three quarters of a mile in length, and is through the solid rock, every foot of which had to be blasted. The other heavy cutting, and consequently the second most expensive part of the line, is a cutting not far from the viaduct alluded to.

A letter from Copenhagen informs us that the American Company for the construction of the great canal between the Baltic and the German Ocean, is so far advanced in its operations as to have completed the survey of the ground, and fixed upon the direction of the works. In accordance with this latest project, which, it will be remembered, is the sequel of many preceding attempts, the canal would start from Brockdorf, on the Elbe, and, passing through the Warden and Taschen lakes, reach the Baltic at a village called Haffkrug. The canal is intended to be 60 miles in length, 180ft. wide, having a depth of 24ft. at least. To secure its connection with the railway system, an inland harbour is to be constructed at Elmshorn, while branches will be made to the important towns of Eutin and Plon, thus bringing Lubeck within a short distance of the new water communication.

The proposal for a new line of railway is being urged by the influential inhabitants of the districts of Aberfeldy, Grandtully, and Kenmore. This line would bring these districts within four hours' communication of the cities of Edinburgh and Glasgow, will be of much importance to the landed proprietors and farmers of the country it traverses, and bring a great increase of traffic to the Crieff Railway.

During a recent storm in Iron Mountain, America, the lightning struck a large ore bank in one of the furnace cuts, and dislodged and threw down from 2,000 to 2,500 tons of ore. To have dislodged the same by powder would have cost the company several hundred dollars.

On Friday evening two gasometers were destroyed at Liverpool. It appears that for some weeks past the contractors for the Garston Junction Railway have been levelling some land in Mersey View Street which had a slight declivity. This land abuts on the wall surrounding the two gasometers, or the south portion of the works, and in filling up the land some hundreds of tons of rubbish were laid against this wall. On the evening in question the entire wall gave way, totally destroying the two gasometers. Upwards of 300,000 cubic feet of gas escaped. One of the gasometers is one of the finest in the kingdom, being upwards of 125ft. in diameter. The estimated cost of the loss of gas is about 200*l.*, and the damage to the two gasometers will exceed 1,000*l.*

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

The Abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following Table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved, and combined with all the advantages of a division into classes. It should be understood that these abridgements are prepared exclusively for this Magazine from official copies supplied by the Government, and are therefore the property of the proprietors of this Magazine. Other papers are hereby warned not to produce them without acknowledgement:—

Steam Engines, &c., 478, 483, 491, 503, 522.

Boilers and their Furnaces, &c., *None.*

Roads and Vehicles, including railway plant and carriages, saddlery and harness, &c., 461, 465, 474, 498, 513.

Ships and Boats, including their fittings, 452, 493, 501, 517, 530.

Cultivation of the Soil, including agricultural and horticultural implements and machines, 457, 496, 511.

Food and Beverages, including apparatus for preparing food for men and animals, 471, 490, 502, 512, 525, 531.

Fibrous Fabrics, including machinery for treating fibres, pulp, paper, &c., 453, 462, 463, 472, 476, 477, 487, 492, 506, 515.

Buildings and Building Materials, including sewers, drain-pipes, brick and tile machines, &c., 482, 524.

Lighting, Heating, and Ventilating, 484, 485, 495, 499, 535.

Furniture and Apparel, including household utensils, time-keepers, jewellery, musical instruments, &c., 460, 469, 470, 480, 481, 486, 489, 500, 509, 526, 527, 528, 534.

Metals, including apparatus for their manufacture, 451.

Chemistry and Photography, &c., 504.

Electrical Apparatus, &c., 458, 468, 514.

Warfare, &c., 454, 488, 507, 510, 529.

Letter-Press Printing, &c., 494.

Miscellaneous, 455, 456, 459, 464, 466, 467, 473, 475, 479, 497, 505, 508, 516, 518, 519, 520, 521, 523.

451. E. M. Stochr. *Improvements in the manufacture of manganese, and in the combinations of manganese with other metals.* (A communication.) Dated Feb. 20, 1862.

Here the manganese ore is pulverised and reduced into pulverised charcoal, or other carbonaceous substance, in a crucible; the necessity of producing soluble salts of protoxide of manganese, and the dissolving of the ore by acids, as was heretofore requisite, is thus obviated. The manganese metal produced is hard, tough, and does not oxidise by exposure to the air. Manganese, when manufactured as above described, may be used for many practical purposes. The second part of this invention consists in combining manganese with copper, zinc, tin, nickel, iron, steel, and other metals or alloys of metals, in order to produce metallic compounds for various manufacturing and metallurgic purposes. These compounds are produced by melting the manganese together with the metal or metals in crucibles, the proportions depending upon the particular purpose for which the metallic compound is required. *Patent abandoned.*

452. D. Wilkie. *A ship's compass, which is not to be affected by local attraction or deviation, to be used by sailing vessel or steamer.* Dated Feb. 20, 1862.

Provisional protection has not been granted for this invention.

453. J. Bleasdale and G. W. Borland. *Improvements in fluted rollers for preparing and spinning fibrous materials, and in the mode of manufacturing the same.* Dated Feb. 20, 1862.

This consists in subjecting soft wrought-iron fluted rollers to the process known as "case hardening," whereby these surfaces are made hard or changed into steel, or partly formed steel; and thus, while the rollers have the toughness of soft wrought iron, their surfaces have a greatly increased quality of resisting wear and injury, and they become stronger and less liable to be bent. *Patent abandoned.*

454. R. T. Pritchett. *Improvements in targets or butts.* Dated Feb. 20, 1862.

This invention refers to such targets or butts as are used for leaden projectiles, and consists in facing them with lead, in order that the projectiles may become fixed thereto or therein, and the loss of the lead of which the projectiles are formed may be thereby prevented. In some cases the inventor dispenses with a backing, and fits blocks, plates, or pieces of lead in frames. *Patent abandoned.*

455. J. Paterson. *Improvements in the use of animal charcoal.* (A communication.) Dated Feb. 20, 1862.

Here the charcoal is fed on to revolving discs with projecting surfaces, adapted in their rotation to throw off and distribute such matter equally in the filtering vessels. A fan, or other suitable blowing or exhausting means, is also employed to draw or blow away the finer particles or dust as it leaves the distributing means. *Patent completed.*

456. J. Paterson. *Improvements in means or apparatus for facilitating the evaporation of saccharine resolutions.* (A communication.) Dated Feb. 20, 1862.

Here the patentee forms the pans with their sides gradually inclining outwards, in order to give an extended surface to the fluid, and facilitate the escape of the vapour. Within such vessels he applies revolving discs, travelling belts, &c., supported so that some part thereof may be constantly in the solution under operation. He also applies to such pans, and immersed in the fluid contained therein, propellers or stirrers, suitably arranged. *Patent completed.*

457. C. Wood. *Improvements in horse-rakes.* Dated Feb. 20, 1862.

Here the person that is using the rake is mounted on a seat or platform, which is so placed as to act by its weight, and the weight of the attendant, as a counter-balance to the teeth of the rake when they are being raised to deliver their load of

collected material, as well as for a counter-balance for the weight of the shafts. By a suitable arrangement of a lever or levers, which are acted upon by preference by the feet or foot of the attendant, the teeth are raised as required. *Patent completed.*

458. L. A. S. CHURCHILL. *Improvements in electric telegraphs.* Dated Feb. 20, 1862.

Here the inventor employs two wires to produce a single sign on the indicating instrument—one to carry the outgoing and the other the incoming current. These wires are caused to take different routes, so that the distance between the outgoing and incoming wire may be considerable, and the wires are uninsulated, by which he means the contacts between each wire and the earth, or places where the current may pass from the wire to the earth, are so numerous or extensive as to render the wire unsuitable for telegraphing in the usual manner, where the return of the current takes place through the earth. *Patent abandoned.*

459. J. SPENCE. *Improved apparatus for transhipping and discharging grain and other substances, and for weighing, screening, and fanning such grain and substances during such transhipment and discharge.* (Partly a communication.) Dated Feb. 21, 1862.

This consists of a suitable vessel provided with a screw or other propeller, actuated by steam or other motive power engine, for the purpose of moving the vessel about in a river or dock. The engine the patentee so arranges that it can be disconnected from the propeller of the vessel, and applied to work a set of elevator buckets attached to endless bands or chains, working over pulleys mounted in a suitable framework, which is capable of being placed vertically, or at any required angle, and which he so mounts that it may be elevated or lowered down the required distance to enable the lower end thereof to be introduced through a hatchway into the hole of the vessel to be discharged. The upper end of the elevator frame he supports upon a suitable framework or tower built on the centre of the vessel, and he fits it to slide rods, or between cheek plates, to admit of the elevator being raised or lowered the required distance. *Patent completed.*

460. R. H. SKELLERN. *An improved self-inking hand-stamp or press.* Dated Feb. 21, 1862.

This invention comprises various improvements (the details of which we cannot here give space to) in that class of hand-stamp or press consisting of two side frames mounted together at or near the top by a cross piece, through which slides vertically a hollow plunger, which is raised by a spiral spring in the interior. *Patent completed.*

461. H. WARD. *An improvement or improvements in ladies' saddles.* Dated Feb. 21, 1862.

The patentee claims making the third or leaping crutch of ladies' saddles movable, without detaching it from the saddle, so that it may be adjusted and fixed to suit the convenience of the rider. *Patent completed.*

462. J. STANDISH and J. GOODEN. *Improvements in machinery or apparatus for stripping or cleaning the flats of carding-engines.* Dated Feb. 21, 1862.

Here the inventors cause each flat to be jointed or hinged upon a pin or centre, so that it can be shifted from its original position to one nearly at right angles to it, and at each side of the card cylinder they use a lever, working loose upon the shaft, and give the levers a traversing motion by cams, levers, or other suitable means. The ends of the levers near the flats have holes or bearings for holding a brush or card, which has a revolving or oscillating motion imparted to it, and the levers are provided with pins or projections for turning up the flats upon their centres. As each flat is turned up by the aforesaid levers, the brush comes in contact with the card on the flat, and efficiently strips and cleans it, and, after all the flats have been stripped and cleaned, the levers are returned to their original position for the purpose of repeating the operation, which is performed continuously with the working of the engine. *Patent abandoned.*

463. W. HAMER. *Improvements in apparatus employed in the preparation of cotton and other fibrous materials.* Dated Feb. 21, 1862.

This relates to the removal of the sliver from the can or coiler, and consists in placing underneath the material a spring of metal, so that, as the sliver is removed from the top of the can or coiler, its lower portion is raised upwards by the spring, and thereby prevents breakage. *Patent completed.*

464. E. S. CREASE. *Improved machinery for drilling, boring, or excavating rock or earthy substances.* Dated Feb. 21, 1862.

Here, instead of striking the drill or boring tool with a hammer, the patentee effects the same by means of a cylinder and piston, with a suitable hammer-head attached to the piston rod to strike the head of the boring tool, which is held in suitable guides. *Patent completed.*

465. R. and W. E. PICKIN. *Improvements in the manufacture of carriage bodies.* Dated Feb. 21, 1862.

Here the patentees make a framework of bars or rods of iron, to which framework they connect other rods or wires laid in pairs or otherwise, so as to produce what may be called a skeleton body. Over or under these rods or wires they attach plain or corrugated woven wire network, which, in some cases, they solder to the rods or wires, where they come in contact to obtain increased strength. *Patent completed.*

466. J. KRASUSKI. *An improved apparatus for controlling fiery horses.* Dated Feb. 21, 1862.

This consists of a small hand winch at the disposition of the driver, placed near the seat, or under the saddle for equestrians. A chain, cord, or strap is wound round this hand winch, which is attached to the fore or hind legs of the horse above hocks by a ligature. If the horse become restive, by turning the winch the cord is tightened, which prevents him spreading his legs. *Patent abandoned.*

467. W. M'ADAM and W. CHRYSTAL. *Improvements in sheaves or pulleys, journals, bushes, and other similar bearing or rubbing surfaces.* Dated Feb. 21, 1862.

The patentees claim the application and use of vitrified ironstone ware, earthenware, china, porcelain, and glass, and in the manufacture of sheaves or pulleys, journals, bushes, bearings, castors, and other generally similar bearing or rubbing surfaces, as described. *Patent completed.*

468. S. SMITH. *Improvements in electro-magnetic engines for obtaining and applying motive power.* Dated Feb. 21, 1862.

This consists in a novel mode of arranging, disposing, mounting, and working soft iron cores or magnets, and other moving parts of electro-magnetic engines, so that, whilst each piece of soft iron shall be attracted or drawn towards and through the hollow central passage way or chamber of a helical magnetic coil, or series of such helical magnetic coils, in turn, a direct action in a straight line through such coils is converted into a continuous rotary motion when the helices are connected with the battery, and a current of electricity is caused to circulate through the properly insulated wires forming the coils, and the action may be regulated by any of the well-known means for making and breaking contact. *Patent abandoned.*

469. H. CHAVASSE, T. MORRIS, and G. B. HAINES. *An improvement or improvements in the manufacture and ornamentation of metallic bedsteads, part of which is also applicable to other articles.* Dated Feb. 22, 1862.

The patentees claim: 1, the preparing and coating iron with tin or lead, or both combined, and afterwards electro-depositing upon the same brass, bronze, German silver metal, or other metallic alloy, and manufacturing such iron, either before or after it is so prepared, into bedsteads, curtain-rods, cornice-poles, balusters, and other articles of metallic furniture. 2, using zinc either upon, or as a substitute for iron, and producing thereon a surface in the manner described for the reception of the electro-deposition of brass, bronze, German silver metal, or other metallic alloy. Lastly, the application of stamped, spun, or drawn zinc, or sheet-tinned ornaments, to increase the size and beauty of the articles intended to be manufactured, and the electro-deposition thereon of brass, bronze, German silver metal, or other metallic alloy. *Patent completed.*

470. W. ASHTON. *Certain improvements in machinery or apparatus employed in the manufacture of braids and similar articles.* Dated Feb. 22, 1862.

This consists in the novel employment and use of a long tubular brush or bearing to support the carriers extending from the bolster plate upwards to any length required, whereby the patentee is enabled to lower the bolster plate, and, consequently, to increase the length of the braiding spindle. The use of the long steadying tube also allows of an increase of the speed of the machine, and considerable smoothness in the action thereof. *Patent completed.*

471. W. H. ROSS. *Improvements in the manufacture of sugar.* (A communication.) Dated Feb. 22, 1862.

This consists principally in using, in the manufacturing or refining of sugar, the phosphates of ammonia in conjunction with sulphurous acid, either gas or liquid, or with any of the sulphates or bisulphates. *Patent completed.*

472. J. KIRKWOOD. *Improvements in looms for weaving.* Dated Feb. 22, 1862.

This comprises various improvements in looms, the object being to admit of the application of steam or other mechanical power, and in one modification of loom embodying them are combined with jacquard pattern mechanism of the single lift class. *Patent completed.*

473. A. BORNEMANN. *Improvements in the mode of constructing fountains.* Dated Feb. 22, 1862.

This relates to fountains adapted not only for pleasure grounds, but for drawing-rooms, conservatories, &c., and consists in constructing such fountains so as to work by atmospheric pressure, without the aid of clockwork or other mechanism for producing and maintaining the requisite pressure. *Patent completed.*

474. J. MILLINGTON. *A new or improved hearse or bier.* Dated Feb. 22, 1862.

This invention is not described apart from the drawings. *Patent completed.*

475. G. T. BOUSFIELD. *Improvements in apparatus for elevating hay, straw, and earth.* (A communication.) Dated Feb. 22, 1862.

This invention is not described apart from the drawings. *Patent completed.*

476. C. H. J. W. M. LIEBMANN. *Improvements in felted fabrics suitable for carpets and other similar purposes, and the apparatus employed therein.* Dated Feb. 22, 1862.

This consists in the application of a woven fabric to a felted fabric as a back to strengthen the felt, which may be of any fibrous substance or material capable of being felted. Also in the means of producing a ribbed, chequered, or other figured surface on felted fabrics, which is effected by the use of a woven fabric made of materials or substances not capable of being felted. *Patent completed.*

477. J. TOWNEND. *Improvements in jacquard engines.* Dated Feb. 22, 1862.

This consists in the use of two grip levers hinged at one end to a stud on which they are capable of vibrating or oscillating, and arranged so that the other ends are guided by a vertical slide frame, so that the upright wires can be lifted and lowered vertically, and thereby avoid or dispense with long or oval eyes in the needles. *Patent abandoned.*

478. J. P. D. CAMP. *Improvements in the arrangement of valves for steam and other engines, and in the means of operating the same.* (A communication.) Dated Feb. 22, 1862.

This invention is not described apart from the drawings. *Patent completed.*

479. D. B. WHITE. *Improvements in apparatuses for protecting liquids from the atmosphere while remaining in and during their discharge from the vessels containing the same.* Dated Feb. 22, 1862.

This invention consists in protecting liquids from contact with the atmosphere prior to and during their discharge from the vessels containing the same, such vessels being so arranged with the aid of impervious pistons and liquid luting, or solid packing, or of oil, as to allow of the storing or drawing off of such liquids without atmospheric air coming in contact with them. *Patent completed.*

480. G. BLAKEY, S. BLAKEY, & J. BLAKEY, and R. WHITE. *Improvements in leggings or gaiters.* Dated Feb. 22, 1862.

To construct a legging or gaiter according to this invention, the patentees take a piece of leather, or any other suitable material, and cut it to the required form; so that when the two vertical or longitudinal edges are sewed or otherwise attached together, the required shape is obtained; and in most cases they prefer that the lower part of the front of the legging or gaiter be cut out so as to form an arch over the instep of the foot, and, if required, a gaiter front may be added to cover the top or part of the top of the foot. For ladies' and children's wear, they insert an elastic gusset in the front or back, or both, or one on each side of the bottom of the gaiter or legging. *Patent completed.*

481. G. J. ORAMS. *A revolving pendant for giving greater security to watches and lockets against theft.* Dated Feb. 22, 1862.

Here the inventor attaches the watch or locket to the bow and pendant by a metal tube or solid wire (he prefers a tube) passing through the pendant and case, and forming an axis upon which the pendant or the watch or locket revolves. The security consists in the pendant, from the fact of its revolving, offering no resistance to, but turning, with a sudden wrench. *Patent abandoned.*

482. R. FOSTER. *Improvements in the construction of buildings or erections to be used for horticultural or other purposes.* Dated Feb. 22, 1862.

This consists in a method of so joining or attaching the several parts which compose them that they may be readily taken in pieces when the owner or tenant of them leaves the premises upon which they are erected, the said several parts so composing such buildings being also readily connected together and erected at or on any other convenient place or places. *Patent completed.*

483. W. B. JOHNSON. *Improvements in steam-engines.* Dated Feb. 22, 1862.

This relates particularly to those engines commonly called "horizontal," but are also applicable to those of other constructions, and consists: 1, in placing the air pump at an angle to the cylinder, and in working it by direct action from the piston-rod or cross head; 2, in a peculiar arrangement of air pump foot and delivery valves. The air pump employed is of the plunger construction, and the plunger is caused to pass beyond the end of the barrel thereof. The foot valve is placed at one end, and, when open, its lid or moving part occupies a space which the plunger has left. The delivery valve is at right angles to the foot valve, and is opposite a space which the plunger occupies when at one end of its stroke. In the plunger the patentee places a valve which opens for the escape of air. In constructing foot and delivery valves, he uses india rubber, so that it is confined laterally between metal surfaces; thus he forms a groove, within which the india rubber is placed; or he causes it to abut against a flange. Another part of the invention consists in placing the condenser and hot well beneath the cylinder; another portion relates to a method of providing for adjustment of the piston rod in reference to the guide blocks. For this purpose he forms the said blocks with a square, which may be altered as required by filling pieces. *Patent completed.*

484. M. A. F. MENNONS. *Improvements in burners for heating by gas.* (A communication.) Dated Feb. 22, 1862.

This invention is not described apart from the drawings. *Patent completed.*

485. W. JOHNSTON. *Improvements in gas and other lamps and stoves.* Dated Feb. 24, 1862.

This invention is not described apart from the drawings. *Patent completed.*

486. G. WEST. *Improvements in the construction of washing machines.* Dated Feb. 24, 1862.

This consists of a box or vessel lined on each side about half way up with vertical ribs of wood, rounded at the front. A short distance above the bottom of the box is a grating composed of similar ribs of wood, forming a false bottom, through which the dirt passes and settles in the space beneath, whence it can be easily washed out; the water is drawn off by a tap placed in one end of the vessel. A frame is made to fit inside the box, and rests on rests placed inside the same. This frame carries a fly-wheel shaft turned by a handle, and is furnished with a crank or excentric, and a connecting rod attached to a rubbing apparatus beneath the frame. The rubbing apparatus consists of a frame of the same width as the inside of the box, but shorter, so that the connecting rod can move it backwards and forwards in the box, so as to give the requisite rubbing motion for washing the clothes or other articles, which are placed between the rubbing apparatus and the ribbed false bottom of the vessel. This frame or rubbing apparatus has an open bottom and ends formed of transverse ribs of wood. The whole of the frame-rubbing apparatus and gearing can be raised up entirely clear of the box or vessel, and lowered again therein when it is required by a rack and pinion, the frame being furnished with guides sliding in grooves in the cast-iron standards of the machine. *Patent abandoned.*

487. J. & R. CUNNINGHAM. *An improved ornamental fabric, and improvements in weaving and in jacquard apparatus.* Dated Feb. 24, 1862.

This improved fabric is of the kind having two or more running covers of differently coloured wefts, there being, by this invention, a sort of, what may be termed, back warps introduced, which back warps the weaving action is made to interweave with the portions of the coloured weft ordinarily forming floats on the back of the fabric. In some cases, however, some of the wefts may be allowed to form floats, to be afterwards clipped or cropped off for the purpose of lightening the fabric. *Patent abandoned.*

488. J. C. HADDEN. *Improvements in small arms and artillery, and in projectiles for artillery.* Dated Feb. 24, 1862.

These improvements in small arms embrace a mode or modes of manufacturing the stocks of rifles with butts constructed so as to be capable of adjustment in respect of the bearing they may take against the shoulder, so that for sighting different objects, whether far or near, the position of the eye or head relatively to the shoulder may remain the same, the said mode or modes consisting of, and including the creating or providing for, the adjustment by a part or parts of the butt being either jointed upon a hinge or pin or joint placed longitudinally, or fitted upon dowels or pins, and removable into different positions, or by a sliding joint or dovetail or other suitable equivalent contrivance. The improvements in artillery consist in manufacturing the gun portions proper of field and other artillery, by surrounding a comparatively light core or inner tube or gun of great strength, such as muskets, metal, or steel, with a succession of girting pieces or lengths of hoops capable of being screwed into each other by screwed socket fittings, or of being otherwise screwed or fitted and fixed together, and in some cases the rearward length either holding a caseable, or a caseable and breech end, the main intention of the girting pieces being to afford weight or resistance against recoil, whether increased strength be or be not afforded by the addition. Certain of the improvements in projectiles have especial reference to projectiles intended to centre themselves in the bore of the gun as secured to the patentee by previous letters patent. One of these improvements consists in forming them with the swells or pro-

jections for receiving the twist situate at the rear of the projectile, and not at the front or forward portion, such swells or projections being either solid, that is to say, cast or formed in one, with the body of the projectile, or separate therefrom but fitted thereto. *Patent completed.*

489. R. WALLER. *Improvements in machinery and apparatus for joining leather and flexible and textile materials, and for the manufacture of boots and shoes and other coverings for the feet.* Dated Feb. 24, 1862.

We cannot here quote the details of this invention at sufficient length for an intelligible abstract. *Patent completed.*

490. T. BLAIR. *Improvements in machinery or apparatus for cutting, chopping, and breaking refined lump sugar and other substances.* Dated Feb. 24, 1862.

This consists in the use of an oscillating frame and sliding saw bench, each provided with an adjustable gauge to suit the size of the piece of sugar, which is made to slide or oscillate against ribband, band, circular, or vertical saws, whereby the piece of sugar is sawn into slices of any required thickness. These slices are deposited upon an endless web, and brought thereby into contact with a pair of feeding rollers, which move the slice forward to a certain point, where a knife descends and cuts the slice into long narrow strips. Motion is imparted to this knife by an excentric crank or other suitable mechanical contrivance. The cut strips or pieces are pushed forward by the action of the feeding rollers over a grating, by which arrangement the small or dust sugar is separated from the larger pieces or strips. After this operation the strips are made to enter a series of tubes or channels placed at an angle of about 45°, so as to allow of the sugar to descend by its own gravity until it comes in contact, at the lower ends of the tubes or channels, with a fence or gauge, placed in advance of a knife which falls upon the strips and severs a piece from the end of each at every tube or channel between the fence and the knife. These pieces are subdivided by small knives fixed at right angles into the before-mentioned knife, the sugar being by this time broken into fragments of the desired size for use. The machine may be made of any size and provided with any number of tubes or channels. *Patent abandoned.*

491. W. CLARK. *Improvements in apparatus for feeding or supplying steam boilers with water.* (A communication.) Dated Feb. 24, 1862.

This relates to improvements in the feed apparatus of steam generators, known as Gifford's "injector," and comprises among other features the following: 1, the steam from the boiler is introduced directly by a pipe into the first converging cone, which latter is fixed in the interior of the apparatus by bolts and flanges; 2, the dimensions of the annular orifice for the injection of the steam at the apex of the first fixed converging cone, may be varied and regulated by the conical part or core of a rod placed in the interior of said cone, which rod, and the conical part of same, are both movable by a screw attached to the end of the rod; 3, on leaving the first converging cone, the steam is immediately introduced into a second hollow fixed cone, formed by the exterior surfaces of the apparatus, which cone also converges, and is in direct communication with the feeding chamber, of which it forms the prolongation; 4, the dimensions of the annular injection orifice, at the apex of the second converging fixed cone, may be varied and regulated by a second and slightly conical enlargement or portion of the same rod which has already passed through the first converging fixed cone, which rod is also movable with the first portion thereof by the screw before mentioned fixed to the end of the rod. *Patent completed.*

492. T. N. KIRKHAM and V. F. ENSOM. *Improvements in bleaching and dyeing yarn and thread when in the form of cops, or otherwise wound.* Dated Feb. 24, 1862.

Here the bleaching or the dyeing liquor is introduced into the interior of a cop, or into a mass of yarn or thread wound into other forms, so that the liquor is pressed from the interior outward through the mass: thus, supposing the yarn or thread is wound into the form of cops, then hollow tubes, in the form of spindles, closed at the smaller ends, are introduced into the cops. These tubes are perforated or formed with numerous holes or passages, suitable for the free passage of the bleaching or dyeing liquor, or cleansing or washing fluid. By these means, when the liquid is forced through the passages in the tubes, the pressure of the liquid tends to separate the layers or coils of yarn or thread outwards, and by such means the liquid gets away in every direction, so that every part is fully acted on. The liquid may, after having been pressed through the tubes, in a direction from the motion outwards, be then drawn back by the open ends of the perforated tubes being put in connection with a suitable pump. When the yarn or thread is wound into masses or other form than that of cops, then suitably-formed tubes are introduced into the interior of the masses, and the liquids are similarly introduced into the interior, and caused to flow outwards. *Patent completed.*

493. P. G. B. WESTMACOTT. *Improvements in constructing and applying armour-plating to ships, vessels, and forts.* Dated Feb. 24, 1862.

For the purposes of this invention, armour-plates are composed of iron or steel, or of both iron and steel; the metal is made into the forms of rings or endless bars, which are shrunk one on the other until the desired dimensions and forms are obtained. The bars of which the rings are composed may be produced by rolling or hammering, or otherwise, and they may be shaped and welded into rings, or the bars or rings may be rolled endless, like to the way in which type-iron and other rings, cylinders, and endless forms are now sometimes made, or they may be otherwise constructed. *Patent abandoned.*

494. T. PARTRIDGE, Sen. *Improvements in apparatus for printing railway and other tickets or cards.* Dated Feb. 24, 1862.

We cannot here devote space to the details of this invention. *Patent completed.*

495. L. DAVIS and F. M. PARKES. *An improvement in the production or manufacture of gas for lighting and heating.* Dated Feb. 24, 1862.

This consists in producing or obtaining gas from the substance known as petroleum or rock oil, by subjecting it preferably in its crude state, that is to say, without previous purification, to considerable heat in a retort or like receptacle, until a gas is obtained from it. This gas the patentees generally pass through a condenser. They sometimes use a vertical retort, constructed double, so that the petroleum may be subjected to a high temperature at two rapidly succeeding intervals. The gas so produced is capable of being stored in a gaseous state for a greater or less time, and afterwards of being conveyed and distributed in a gaseous state for lighting and heating purposes, in the same way as the common coal gas now in use. *Patent completed.*

496. R. A. BROOMAN. *Improvements in reaping and mowing machines.* (A communication.) Dated Feb. 24, 1862.

This invention is not described apart from the drawings. *Patent abandoned.*

497. F. ST. GEO. SMITH. *Improvements in machinery for grinding or reducing quartz, bones, grain, and other substances.* (Partly a communication.) Dated Feb. 24, 1862.

This invention has for its object improvements in mills for grinding or reducing quartz, metallic ores, bones, bark, grain, and other mineral, animal, and vegetable substances. The patentee takes a cylindrical drum by preference toothed on the inner surface, and mounts arms on a spindle or axis, made to revolve very rapidly inside the said drum by means of a strap and pulley on the outer end of the spindle, or by any other means of communicating motion. The material to be operated upon is fed through an opening in the side of the drum near the axis, and the revolving arms meeting the material when inside the drum, dash it by centrifugal action with great violence against the internal circumference of the drum, whereby the material is broken to pieces. At one portion of the circumference he places an exit pipe, through which the particles, when sufficiently reduced, are driven by the blast of wind caused by the revolving arms. The exit pipe opens into a large chamber, in which the ground material subsides, and in the event of the comminution being required of different degrees of fineness, he makes the said chamber of considerable length. The largest particles subsiding first, and nearest to the entering end of the chamber, and so on down to the finest particles, allows of the separation being easily effected. *Patent completed.*

498. W. E. NEWTON. *Improvements in the joints or chairs of the permanent way of railways.* (A communication.) Dated Feb. 24, 1862.

This consists in shrinking the iron chair to the rails at their joint, and thus preserving the whole surface-bearing of the chair and rails, and making an externally solid and firm joint without the necessity of keys or wedges for holding the rails and chairs together. *Patent completed.*

499. J. CARNABY. *Improvements in turning, managing, and regulating the taps and valves of gas pipes.* Dated Feb. 25, 1862.

This invention is not described apart from the drawings. *Patent completed.*

500. J. WOODROW. *A certain improvement in the manufacture of hats or coverings for the head.* Dated Feb 25, 1862.

This relates to that part of hats or other coverings for the head called the brim, and especially to such brims as have the under side or surface covered with silk or satin, or other smooth substitute for plush, the present improvement being an extension of such covering to the upper surface also. The silk or satin is to be stretched over the upper surface of the brim, and passed over the edge to the under side in one piece, whereby the binding of the edge of the brim is dispensed with, and the upper surface is prevented from becoming disordered by the wearer. In the employment of plain or figured satin in one piece to cover the upper and lower parts of the brim, it will be evident that no binding will be required, consequently, the stitching usually required is dispensed with, and a thinner edged brim is obtained. The satin is cut in one piece to form the circumference of the brim, and sufficiently wide to cover the upper and lower portions, the same joining the ends being back-stitched at the back part of the brim. *Patent completed.*

501. D. WILKIE. *A composition to be used on the bottoms of sailing vessels and steamers for the prevention of barnacle and other matters adhering thereto while employed in sea water.* Dated Feb. 25, 1862.

This composition is made from the sea-weed commonly called "sea tangle" or "wreck," likewise a fluid extracted from haddock or other fish, which are to be amalgamated into one fluid or body. *Patent abandoned.*

502. J. PIDDINGTON. *An improved machine for shelling or husking all kinds of grain.* (A communication.) Dated Feb. 25, 1862.

This consists in constructing a machine for the above purpose in the following manner:—In a suitable framing the patentee adopts the following parts at the top and centre of the said framing. He fixes a hopper or funnel of sheet metal for supplying or feeding the grain into the machine, through a hole formed around a boss of the said casting. The said shaft is supported by its lower end in a step piece fixed to the bottom of the framing of the machine, and has a pulley fixed thereon for imparting rotary motion to the said shaft and to the horizontal plate before named. The under side of this said plate is furnished with a number of pieces of fine hard wire, set in gypsum, so as to form a kind of brush, the points of the wires projecting sufficiently beyond the gypsum to take off the shell or husk of the grain, which is deposited on a perforated circular plate beneath, fixed to another plate or casting bolted to the sides of the framing of the machine. This last-mentioned casting is formed with arms, from which proceed a number of concentric rings of metal, projecting upwards, the upper edge of each ring being formed sharp or knife-edged; at some distance below the rings aforesaid, another casting of a cup shape is fixed by its side or flange to the framing of the machine, and is used to receive the grain and loose shells or husks thereof. The operations of this machine are as follow: As the wire brush revolves, it rubs the grain which is on the perforated plates beneath the grain, and shells or husks removed thereon pass through the perforations in the said plate and fall into the receiver below; and it is this revolving brush and perforated plate operating upon the grain which constitutes the important feature of novelty in this invention. *Patent completed.*

503. J. PIDDINGTON. *Improved condensing apparatus adapted for high-pressure steam engines, especially locomotive engines.* (A communication.) Dated Feb. 25, 1862.

This invention is designed for effecting the following principal objects: 1, to prevent incrustation in the boiler; 2, to economise water; 3, to supply the feed water into the boiler at a temperature of 60° to 70° Beaumé; and lastly, to increase the effective power of high-pressure engines, and to economise fuel. *Patent abandoned.*

504. E. BLISS and H. CAMPLOUGH. *Improved means for viewing microscopic photographs and other minute objects.* Dated Feb. 25, 1862.

This consists in having a circular disc of metal or other suitable material, with small sight-holes perforated therein, at a convenient distance from the edge, and at a proper space apart, and placing opposite to each hole the photograph or object to be inspected, and having such discs and objects enclosed in a case with a microscopic lens fixed therein in the line of the holes in the disc, and a hole through the other side of the case directly opposite the lens, so that, by causing the disc to revolve, the objects placed on or connected with the disc may be brought seriatim in front of the lens in the case, and viewed through it. Of course, if the disc be of clear glass, no sight-hole will be required in it. The case may be caused to revolve by toothed wheels or other means. *Patent completed.*

505. W. CLARK. *Improvements in tobacco pipes.* (A communication.) Dated Feb. 25, 1862.

This relates to an arrangement of pipe by means of which the smoke is prevented from traversing the lower layers after escaping from the upper part. For this purpose the patentee makes use of an ordinary pipe of any form, material or dimensions, in the bowl of which he places a smaller hollow chamber or bowl, which serves for the passage of the smoke. Several rows of holes are made obliquely in the inner lining, so as not to be liable to choke with the ashes, which holes allow of the passage of the smoke into the annular space in communication with the suction tube or stem. *Patent completed.*

506. T. WATSON and R. DRACUP. *Improvements in means or apparatus for preparing and combing wool and other fibres.* Dated Feb. 25, 1862.

For apparatus for preparing and combing wool and other fibres, such fibres are operated by teeth in bars or instruments, to which a progressive motion is given by the simultaneous movement of pairs of toothed wheels; but it sometimes happens that, through such wheels being rigidly fixed to their shaft, and some obstruction either in the fibre treated or in the working of the mechanism arising, breakage takes place. The object of this invention is to remedy this evil by connecting such wheels to their shaft, so that, whilst uniformity of action may be secured, a yielding may take place when any undue obstruction arises. For this purpose the patentees connect the bosses of such pair of wheels together by a bar or bars, or other suitable connecting means, and apply a strap or collar to embrace the shaft, and they adjust the amount of adhesion thereto by set screws or other suitable means capable of adjustment to the pressure ordinarily desired to be exerted. *Patent completed.*

507. C. MINASI. *Improvements in cartridges, and in apparatus for facilitating the proper aiming with fire-arms.* Dated Feb. 25, 1862.

With reference to cartridges, this consists in so partially cutting, stamping, perforating, or acting upon their cases, covers or wrappers, that they will readily open, tear, separate, or part at a certain place or position, or places or positions, as required, before being placed in the gun. Also in manufacturing cartridges with a plug, stopper, cork, or other equivalent contrivance for holding in the powder and keeping it dry, and which is removed when the twisted end is broken off or removed. The invention comprises the constructing the stocks or supports to or upon which the barrels of rifles are mounted with the butts, or a part of the butt, hinged or jointed to the remainder or barrel, holding portion of the stock, by a pin or bolt passing through the two parts from side to side, so that by adjusting the position of the butt, the rifleman, whether firing at short or long range, may be enabled, while properly sighting the object aimed at, to place his eye or cheek as low down as may be convenient. *Patent abandoned.*

508. C. W. HECKETHORN. *Improvements in obtaining and applying motive power.* Dated Feb. 25, 1862.

Here the patentee makes a wheel, having, say, twelve hollow square spokes, with openings running their entire length either at the top only, or at both the top and bottom. In the spokes are tubes, containing a quantity of mercury, and running on twelve rollers. When the wheel is in motion, some of the tubes, that is, those on the descending side, will project beyond the periphery of the wheel, and the mercury will have run to the outer end of the tube, while on the ascending side the tubes will be brought close to the centre of the wheel (the mercury at the same time approaching the inner end of the tube) by one or two inclined planes (with or without the use of a cam) which carry the said tubes up, there being but one inclined plane required where there are openings at the top and bottom of the spoke. When the inclined plane is arranged between the openings, in which case an extra friction-wheel will be required, if there is an opening only on the upper side of the spokes, the tube has attached to it a metal rod projecting on both sides, and having wheels attached to it, which run on two inclined planes arranged on either side of the wheel. *Patent abandoned.*

509. J. IMRAY. *Improvements in hinges.* Dated Feb. 25, 1862.

These improvements apply, in the first place, to a mode of constructing cast iron hinges of the kind commonly known as collinges or spherical hinges. The joint of such a hinge ordinarily consists of a wrought iron or steel ball-ended pivot, which is fixed tightly in the knuckle, the ball end of the pivot being made true and smooth, so as to turn freely in a cup which forms the step of the hinge; but instead of making the pivot a separate piece from the knuckle, and fixing it thereon, the patentee chill casts the pivot in one piece with the knuckle, and afterwards renders it smooth by scouring it with emery or other suitable polishing material. The improvements apply, in the second place, to the construction of spring hinges, and the shoes, centres, or hangings used in connection therewith. *Patent completed.*

510. J. WHITWORTH. *Improvements in manufacturing projectiles.* Dated Feb. 25, 1862.

According to this invention projectiles are made having the required regularity or shape by placing the projectile in a chuck, and turning the fore and rear parts simultaneously, or by consecutive operations, without removing the projectile from the chuck in which it is held. The patentee uses for this purpose a machine having a holder or chuck, in which the projectile is held in the middle, or intermediate of its length, and the machine is arranged so that the chuck may be made to revolve, and so that the tools which produce the required shapes to the ends may be moved up to and from the fore and rear parts respectively of the projectiles; or the projectile may be held and presented to revolving tools. In applying to projectiles suitable lubricating materials, a portion of the surface is coated with the lubricator applied in spiral strips or ribs, that is to say, those parts are coated or more thickly coated, which, when the projectile is in the rifled

barrel, correspond with its grooves or recesses, by which means provision is made for easy loading without greatly reducing the diameter of the projectile. The projectile may be covered with paper or a thin metallic or other suitable coating to prevent the barrel from leading, and in that case the lubricator is applied, or more thickly applied, spirally upon the covering material. *Patent completed.*

511. W. MC. I. CRAUSTON. *Improvements in machinery for reaping and mowing.* (Partly a communication.) Dated Feb. 25, 1862.

One object here is to keep the cutting apparatus as nearly in line with the axle or centre of the driving wheel as possible, and at the same time to so unite the finger and cutter bar to the main frame as that they may be raised up or let down as circumstances may require. Another object is so to construct a track clearer, and to so apply it, that the act of drawing it along the land shall cause it to rotate. *Patent completed.*

512. C. KINGSFORD. *A new composition for the manufacture of bread.* Dated Feb. 25, 1862.

The object of this invention is to form such a composition with flour as will, when submitted to the usual mixture with water or milk for the purpose of making dough, give rise to the escape of carbonic acid gas in sufficient quantity to "lighten" or "make porous" the dough, and so render yeast or other fermenting agent unnecessary. The patentee grinds into fine powder, separately, tartaric acid, bicarbonate of soda, and common salt, and mixes them thoroughly together in the following proportions, that is to say:—Tartaric acid, 25½ ounces; bicarbonate of soda, 27 ounces; common salt, 14 ounces, making together 66½ ounces, which he mixes with 196lbs. of flour, taking care that the whole mass is completely incorporated. *Patent completed.*

513. P. J. GUYET. *An improved coupling for uniting pipes between locomotives and tenders, also applicable to the coupling of other pipes.* Dated Feb. 25, 1862.

This invention is not described apart from the drawings. *Patent abandoned.*

514. H. W. COOK. *An improved mode of, and apparatus for, propelling by means of electricity.* Dated Feb. 25, 1862.

This relates to a new and improved mode of, and apparatus for, propelling carriages by electricity. In order to effect this object, the patentee makes use of that attractive power or force which a coil or helix exerts upon or induces in a bar of soft iron (placed as a core within its spiral) during the passage through the length of the wire of an electric current, and which attractive force is the force or power known in physics as the axial force. The iron bar being about the length of the coil, air attractive force is exerted or set up, and tends to bring the centre of the coil to a position identical with that of the centre of the bar. He proposes then, by suitable arrangements, to make use of this force for the production of motion in a continuous, rectilinear, or other direction. *Patent completed.*

515. J. BOOCOCK and T. DAVENPORT. *Improvements in machinery for preparing, spinning, and doubling cotton and other fibrous materials.* Dated Feb. 26, 1862.

The 1st part of this invention, which is applicable to slubbing frames, intermediate frames, and roving frames, or any other machines of the like nature for preparing cotton or other fibrous materials to be spun, consists in causing the bobbins and rollers to revolve in a frame, which frame also revolves on its own axis, for the purpose of putting any requisite amount of twist into the fibrous material, at the same time that it is being wound on the bobbins. In performing this part of the invention, the inventors mount both rollers and bobbins in frames or suitable bearings, and cause the rollers to revolve by bevil wheels, friction rollers, or in any other convenient manner, such motion being communicated from the spindles on which the above-mentioned frames are mounted. The 2nd part consists in an improved method of giving motion to the lifting rails or equivalent parts of machines for preparing, doubling, &c., and also in an improved tapering-off motion. In performing this part of the invention, they cause the heart lappet of such machines to actuate a lever, one end of which is fixed to the machine in any convenient place; to this lever is fixed a ratchet wheel and lappet, which actuate a stud moving in a radial slot in the said lever; a catch which is fixed to the frame causes the ratchet wheel to move one or more teeth every time the lever descends, and by this means the traverse or guide is shortened and the tapering off at the ends of the bobbins effected; when the bobbin is full, the stud has reached the end of the radial slot, and actuates the knocking off motion for stopping the machine. *Patent abandoned.*

516. A. GREEN. *Improvements in machinery for bordering paper, envelopes, and cards with black or coloured borders.* Dated Feb. 26, 1862.

These improvements in the method and apparatus for bordering paper, envelopes, and cards with black or coloured borders consist in fitting to each side of a table or bed of any desired length and width a movable guide, carrying a series of pins, their distance apart being regulated according to the width or depth of border desired; or, instead of pins, corrugated metal, or other suitable contrivance, may be fixed in the guides. The guides are free to move up and down in slots over screws which enter the sides of the bed. Bars connect each end of the frame, and support a shaft extending beneath the bed the whole length thereof, and carrying a toothed wheel at each end, into the teeth of which a ratchet works, whereby the frame is raised, to raise the pins above the surface of the table, or lowered to lower them, and let them lie flush with or below the surface thereof. The paper envelopes or cards are placed in the spaces between the pins; the guide is lowered, the ink or colour applied in the ordinary manner, and the paper removed. *Patent completed.*

517. A. STEPHEN, junior. *Improvements in the construction of ships or vessels.* Dated Feb. 26, 1862.

The object here is to prevent or diminish the injurious corrosion supposed to arise from galvanic action, such as that hitherto occurring where the constructive details of ships or vessels have consisted of two different metals and wood combined and disposed so as to be accessible to moisture; and the invention consists in applying to such parts a protecting impervious or non-conducting covering, coating, or varnish of a viscous, resinous, bituminous, or vitreous substance, such as waterproof glue, or a waterproof or insoluble cement, such as Portland cement, or a combination of such coverings, coatings, or varnishes may be applied to the said parts. This improved treatment is designed in constructing ships or vessels of wood and iron combined; as, for example, with frames of iron and planking of wood, and with or without an external sheathing of copper or other metal or alloy different from iron; and it is equally applicable in all cases wherein different metals are combined in such a way, and are so situated or disposed as to be accessible to moisture or water. *Patent completed.*

518. G. DAVIES. *Improvements in emptying or draining the water from careening docks in maritime ports.* (A communication.) Dated Feb. 26, 1862.

This consists principally in the utilisation of the tides for the purpose of effecting the necessary drainage, which system appears to result from the very nature of the operation in tidal ports. The ordinary process is to admit the vessel into the dock at high water, and, placing it in the required position, to allow the water to ebb until it has attained its lowest level; the dock gates are then closed, and the draining commences. It will be readily understood that a reservoir might be made near to the dock into which the water is admitted, and retained at the high water level by the closing of a shuttle or sluice, and when the time of drainage arrives, the water retained in the reservoir may be used to actuate a tubular or other hydraulic machine, which, giving motion to the pumps, will effect the emptying or draining of the dock. *Patent abandoned.*

519. G. REES. *Improvements in the construction of marine sub-ways.* Dated Feb. 26, 1862.

This consists in the use of a floating caisson or chamber, having an opening above the surface of the water, within which chamber the construction of the sub-way is carried on. The sub-way is formed of a tube, or series of iron tubes, flanged internally, cylindrical being preferred. On one side of the chamber there is an opening corresponding to the size of the tube, and sliding thereon in a water-tight manner. As the tube is lengthened, the chamber is pushed forward, and clay, stones, concrete, or other suitable substances, are brought into the chamber through the tube, and elevated and deposited on the outside thereof, so as to form a support and protection for the sub-way as it is completed. *Patent abandoned.*

520. A. D. DUPARET. *Improvements in the ornamentation of tissues.* Dated Feb. 26, 1862.

This consists in ornamenting crape, muslin, gauze, or other similar transparent or light tissues, such as cashmere, by painting on such tissues (previously stretched on a proper frame) flowers, foliage, or other similar ornaments, by painters' pencils and water colours mixed at the moment. The same are to be used with gelatine dissolved in water by a water bath. *Patent abandoned.*

521. J. DOTHEE. *Improvements in the colouring or dyeing of horse-hair tresses, hats, or ornaments.* Dated Feb. 26, 1862.

This consists in colouring or dyeing horse hair, &c., in any required shade, by vegetable or mineral colours mixed up or diluted with spirits of wine, collodium, or other suitable rapidly volatizing menstruum, or a mixture of two or more of such menstrua, which, by rapidly volatizing, do not allow sufficient time for the horse-hair to crisp or distort, as would be the case if other non-rapidly volatizing menstrua were to be made use of. *Patent abandoned.*

522. J. H. BENNETT. *Improvements in steam generators, and in engines to be worked by atmospheric pressure, or steam and air combined.* Dated Feb. 26, 1862.

This consists in employing a small supplementary boiler and furnace. An air pipe is entered into an ordinary boiler without a furnace, and is passed to the back, and then brought to the front, or circulated in any other way, and then passed into the supplementary boiler, at the top of which there is a pipe connected with the ordinary boiler for the purpose of supplying it with steam and hot air. Cold air is forced into the air pipe by a fan-pump or other contrivance, and water is supplied to the supplementary boiler in the usual way. When heat is supplied to the supplementary boiler, steam is generated, and the air forced through the pipe in the ordinary boiler becomes heated, which hot air, with the steam, passes into the ordinary boiler and heats the pipe, and causes the continual supply of air to become heated as it passes onwards to the supplementary boiler. The improvements in engines worked by air and steam combined, consist in the use of one or more cylinders provided with slide or other valves, and forming a vacuum on one side of the piston or pistons, and using air either singly or combined with steam for the pressure. The crank shaft of the engine has cranks for working the pumps which form the vacuum, and supply air to the pipes which pass through the boilers. The inventor also uses air, either singly or combined with steam, in connection with a vacuum for working rotary engines. In the interior of a stationary cylinder there is a shaft working in suitable bearings. To this shaft is fixed an inner wheel, having upon it projections working against the interior of the cylinder, and acting as a piston. At both ends of the stationary cylinder on the outside are bands for the purpose of holding the packing and keeping the parts tight. *Patent abandoned.*

523. T. KING and R. VARVILL. *Improvements in apparatus for controlling the flow of fluids for flushing water-closets.* Dated Feb. 26, 1862.

This relates to the apparatus immediately in connection with the cistern containing the flushing fluids, and, though applicable to all cisterns, is especially so in large towns, where a small or intermediate cistern is supplied from the street mains, or from a cistern at an elevation, the object being to prevent the waste of the said flushing fluids. To the ordinary connections of the hand-lift or pressure-seat arrangement the patentees joint, or otherwise connect, a lever, which is carried into the cistern, and balanced or supported on the end of the horizontal plug or barrel of a tap fitted to the supply pipe. On the other end of this lever is affixed the float, and between the said tap and float is attached a chain or lever, which reaches to, or near to, the bottom of the cistern, and operates the overflow or flushing-valve. The overflow pipe is cast with the cistern, and communicates with the flushing or waste-pipe in the usual way. By this arrangement, when the part of the lever outside the cistern is acted on, the float will be raised, the supply-tap shut, and the outflow or flushing-valve opened; but as soon as the lift or pressure-seat is left at freedom, the float falls and opens the supply-tap, until such time as the cistern is again filled, thus preventing more than the quantity contained in the cistern from being used by one movement. *Patent completed.*

524. J. CLIFF. *Improvements in glazing stoneware, red clay ware, porcelain, and other kinds of earthenware.* Dated Feb. 26, 1862.

This consists in using in lieu of the ordinary kiln with open fires, ovens, furnaces, or chambers for glazing goods, an oven or kiln heated by flames or jets of gas, thus generating heat without deposition of ash or dust on the goods. When such furnace is sufficiently heated, common salt, metals, salts, or other glazing materials or agents may be applied directly amongst the goods or slabs or open saggers containing the goods in the ordinary way, namely, in at the furnace mouths, or by scattering from orifices in the top or sides of said furnaces. *Patent completed.*

525. W. MILLER. *Improvements in the manufacture of sugar.* Dated Feb. 26, 1862.

This invention is not described apart from the drawings. *Patent completed.*

526. C. L. KNOLL. *Improvements in pianofortes.* Dated Feb. 26, 1862.

Here in oblique and cottage pianofortes the hammers are caused to strike from the back of the instrument against the strings or scale, whereby the body of the instrument may be extended in width beyond that of the key board. The patentee employs a compound rest plank, formed of wood, with a plate or bar of iron at the upper and lower surface thereof, the whole being covered with sheet or cast brass. The balance key pins have their upper ends made of an oval shape in horizontal section, and are so fixed in the key frame that their transverse diameter shall be parallel with the lines of the slots and keys. *Patent completed.*

527. W. CLARK. *Improvements in the clasps or fastenings of bracelets, neck chains, and other articles of jewellery.* (A communication.) Dated Feb. 26, 1862.

This catch is formed of an elastic strip, which itself forms the spring, and is bent so as to form two arms. It is fixed rigidly or jointed to one part of the ornament. In this strip the patentee also makes a cavity which receives a projecting point formed inside of the socket, plate, or part into which the spring enters. *Patent completed.*

528. E. G. BRUZAUD. *Improvements in pianofortes.* Dated Feb. 26, 1862.

This consists in combining with the strings of each note, at or near the bass end of the instrument, two dampers which come in contact with the strings at two points in their length at a distance the one from the other, whereby the vibration of the strings is checked. *Patent completed.*

529. W. P. SAVAGE. *Improvements in firearms.* Dated Feb. 26, 1862.

Here the patentee applies, immediately behind the trigger guard, in the small of the butt where it is grasped in firing, a lever mounted on a centre, kept in position by a spring, which tends to project it out a short distance from the stock, so that the hand, in grasping the piece in the position for firing, may move the end of the lever inwards. He causes the lever to act on a stud, pin, &c., which stands up in front of the half bent of the tumbler in such position that, were the tumbler released by the sear, it would be immediately caught by the stud or pin. When the piece is grasped for firing, the movement so produced in the lever withdraws the stud or pin. *Patent completed.*

530. J. MEDHURST. *Improvements in apparatus for reefing and furling the top sails, courses, and other square sails of vessels.* Dated Feb. 26, 1862.

For the purposes of this invention, in arranging top sails and other square sails (except courses) the yard is made of iron, and hollow; and there is a bar or tube by preference of iron cased with wood in the centre of the hollow part, and somewhat exceeding the breadth of the head of the sail in length. This bar or tube is so arranged that it can revolve on centres or bearings at its ends. On this bar or tube the sail is laced, and when it is made to revolve, the sail is wound around it. In order to reef the sail, the yard is lowered, and the sail is at the same time wound up upon the bar or tube which is caused to revolve. The apparatus is attached in the following manner:—A chain from the deck passes through a sheave in the mast over the yard, and then around a chain wheel fixed to and above the yard at the slings; the chain then passes up and around a second sheave on the mast, and then returns to the deck, so that, when the yard is lowered by slacking off one end of the chain, the whole weight of the sail roller and yard being pendent on the chain, will cause the chain wheel to revolve. This chain wheel puts in motion two axes extending in either direction towards the extremities of the yard; these have pinions at their ends which gear with cog wheels at the ends of the roller to which the sail is attached. As a security against the roller being bent or otherwise damaged by the wind blowing in the sail, there is a broad hook made by preference of sheet iron, and so placed as to support the middle of the roller; this hook is connected with a purchase, so that when the sail is set, or after it has been reefed, the hook may be made to take the weight of the sail. Both ends of the sail are arranged so that they may be hauled on or slacked off from the deck, so that any amount of rotation may be given to the roller. *Patent completed.*

531. J. SMITH, Sen. *Improvements in drying wheat and other grain.* Dated Feb. 26, 1862.

These improvements consist in causing the air used for raising grain to be heated, and to be used in a heated state, by which the grain will be dried and improved when being raised. *Patent completed.*

532. G. TORR. *Improvements in and an improved apparatus for manufacturing and re-burning animal charcoal.* Dated Feb. 27, 1862.

This invention is not described apart from the drawings. *Patent completed.*

533. S. ADAMS. *Improved arrangements for effecting an equilibrium of fluid or gaseous pressure upon other valves.* Dated Feb. 27, 1862.

This invention has for its object the production of an equilibrium of the steam fluid or gaseous pressure on the valve, by causing the steam fluid or gas to act with equal pressure on opposite sides of the valve at the same time, thereby obviating the loss of power caused by the unbalanced pressure on the valves as they are ordinarily constructed and arranged. For this purpose, recesses are formed in the door or front of the slide valve box, or in the valve, in such situations as to admit of the steam fluid passing at the same time to opposite sides of the valve. There are also passages through the valve, so as to form communications between the ordinary ports leading into the cylinder and the recesses. By this arrangement the pressure on the valve of the steam fluid, as it enters or escapes from the cylinder through the ordinary ports, is balanced by the pressure of the same on the opposite part of the valve, thereby effecting a constant equilibrium of pressures on the valve. *Patent completed.*

534. C. Clark. *Improvements in tea and other trays for the table.* Dated Feb. 27, 1862.

This invention consists in making trays for the table with a movable or rotating plate, upon which the tea, coffee, and other services are placed so as to be filled from the urn as they move or revolve therewith. *Patent abandoned.*

535. W. A. Gilbee. *Improvements in the construction of fire-grates for steam and other boilers, and suitable to all kinds of fires.* (A communication.) Dated Feb. 27, 1862.

This consists in constructing grates with fire-bars, having conical, tubular, or other shaped recesses or grooves formed in them, and arranged in a line with each other in the length and breadth of the furnace, and permitting the circulation of air received from without by suitable openings in the front and around the grate. The bars are placed parallel to the door of the furnace. The grate is formed by placing a number of the said fire-bars side by side and parallel to each other. The recesses of the bars begin at the entrance of the furnace, the framework and plate of which are perforated with holes corresponding, and in a direct line with the recess in the fire-bars, for the admission of the air into the furnace. *Patent abandoned.*

PROVISIONAL PROTECTIONS.

Dated May 31, 1862.

1617. I. Villa, 12 Denmark Street, Soho. A new and improved method of exhibiting terrestrial and astronomical phenomena, and of facilitating the solution of problems relating thereto, without the aid of calculation.

Dated July 21, 1862.

2075. W. Clark, 53 Chancery Lane, engineer. An improved pomade or balsam. (A communication.)

Dated August 7, 1862.

2215. R. A. Brooman, 166 Fleet Street, patent agent. Improvements in covering ships and vessels built of wood, or iron ships with a backing of wood, before placing iron, steel, or other armour plates on such ships and vessels. (A communication.)

Dated August 9, 1862.

2236. G. T. Bousfield, Loughborough Park, Brixton. Improvements in apparatus to be used in the manufacture of hat bodies. (A communication.)

Dated August 14, 1862.

2280. A. Walker, Liverpool, optician. A new instrument to determine or ascertain the depth of water and the distance a ship has run.

Dated August 16, 1862.

2306. R. Barclay, Paris, Canada West, watch and clock-maker. Improvements in chronometers and other time-keepers.

2308. C. H. J. W. M. Liebmann, Huddersfield, merchant. Improvements in machinery for finishing textile fabrics.

2310. M. Iturriaga, Colonel in the Army of Her Majesty the Queen of Spain, Tavistock Street, Bedford Square. Improvements in fire-arms.

Dated August 18, 1862.

2312. G. Chapman, Edinburgh, gentleman. Improvements in reaping machines.

2314. J. Cuneg, Great James Street, Bedford Row. Improvements in depositing silver and other metals on fabrics and other materials.

2316. W. E. Newton, 66 Chancery Lane, civil engineer. Improvements in connecting plates, sheets, or slabs of metal or other materials, and fastening the same on to framing applicable to armour-plating for ships, vessels, or batteries, and to roofing and other similar purposes.

Dated August 19, 1862.

2320. T. Wilkinson, Rathmines, Dublin, commercial clerk. Improvements in machinery or apparatus for singeing pigs.

2322. G. H. Dembinski, 13 Rue de l'Oratoire, Paris. A motive apparatus, and processes proper for giving to it a continuous motion and unlimited strength.

2324. W. J. Hoyle, engineer, and J. Proven, millwright, Halifax. Improvements in mechanism and arrangements for supplying lubricating matter to the cylinders of steam engines, and to the bearings and other surfaces of mechanism.

Dated August 20, 1862.

2326. J. G. Tongue, 34 Southampton Buildings, Chancery Lane. Improvements in processes and apparatus for extracting the natural wax or fatty matters from wool, hair, or other animal or vegetable substances containing the same, and in the application thereof to various useful purposes.

2328. C. Callebaut, 2 Rue Sainte Appoline, Paris. Improvements in sewing machines.

2330. W. H. Hutchinson, Newton Heath, near Manchester, starch manufacturer. Improvements in the manufacture of ammonia and the prussiates of potash or soda, and in apparatus employed in such manufactures.

2331. J. Standish, Egerton, near Bolton, and J. Gooden. Improvements in machinery or apparatus used in the preparation of cotton, wool, flax, or other fibrous materials to be spun.

2332. S. Wilkes, Rue St. Honore, Paris. An improved attachment for door knobs.

2333. C. Chinnock, Brooklyn, New York, merchant. Improved construction of corkscrew.

Dated August 21, 1862.

2334. S. J. Paris, Manchester, engineer, and W. Bate, Salford, telegraph engineer. Improvements in alphabetical electric telegraphs.

2335. J. C. Schemmann, Hamburg, merchant. Improvements in the manufacture of steel.

2337. G. Davies, 1 Serle Street, Lincoln's Inn, civil engineer. Improvements in governors for steam engines.

2338. T. Clements, managing engineer, and P. Llewellin, John and J. W. James, brass founders, Bristol. Improvements in the construction of a self acting lubricator for lubricating various parts of steam engines.

2340. A. Boubée, Paris. An improved veil protector.

Dated August 22, 1862.

2341. S. F. Griffin, New Adelphi Chambers, civil engineer. Improvements in apparatus to be used in the distillation of petroleum or any oleaginous, resinous or alcoholic bodies.

2344. W. Barrett, Norton Furnaces, near Stockton-on-Tees. Improvements in casting railway sleepers and chairs where tie bars are used.

2346. J. Mackay, Glasgow, manufacturing chemist and importer of foreign goods. Improvements in the manufacture of soap powder.

2347. R. Harrington, Northampton Street, Birmingham, manufacturer. Improvements in umbrellas and parasols, and in the manufacture of parts thereof.

2349. D. Moore, Brooklyn, of Kings and state of New York. Improvements in breech-loading fire-arms.

2350. G. Bottomley, Leeds, gentleman. Improved apparatus for expressing moisture from pulpy or solid substances.

2351. D. Moore, Brooklyn, of Kings and state of New York. Improvements in revolving fire-arms.

2352. W. Carwood, Stepney, engineer, W. Boas, Bromley, engineer, and C. Colwell, Belvedere Place, Southwark, gentleman. Improvements in apparatus for propelling ships and other vessels.

2353. T. Wood, Manchester, engineer. Improvements in the slide valves of steam engines.

Dated August 23, 1862.

2357. M. K. Angelo, Gloucester Place, Portman Square. Improvements in apparatus used in the manufacture of shell-lac.

2358. M Henry, 84 Fleet Street. Improvements in stuffing boxes and their packings. (A communication.)

2359. C. H. Roeckner, Marsh Street, Bristol. Improvements in syphons for discharging or drawing off large bodies of water, and in the mode of charging, fixing, and constructing same, whereby they are rendered permanently self-acting.

2360. W. E. Newton, 66 Chancery Lane, civil engineer. Improvements in the mode of and apparatus for treating fermentable substances for brewing and distilling. (A communication.)

Dated August 26, 1862.

2368. J. Rider, Basinghall Street, Leeds, iron merchant and engineer. Improvements in the construction of fencing posts or standards, to be used either for straining or otherwise sustaining fences; the said improvements being also applicable to all kinds of gate posts, telegraph poles, signal posts, or other upright standards or pillars.

Dated August 27, 1862.

2370. A. Crichton, Glasgow, mechanic. Improvements in looms for weaving ornamental fabrics.

2372. H. Harben, Oxford Villa, Haverstock Hill, gentleman. Improvements in the manufacture of paper and other productions in which fibrous material is employed.

2374. R. Sims, Bedford Foundry, Leigh, agricultural implement makers and ironfounders. Improvements in machinery or apparatus for pulping, stripping, or slicing turnips and other vegetable substances.

2378. W. M. Mayes, Hoxton, civil engineer. An improvement in, or addition to, wheels particularly applicable to the wheels of railway and other carriages.

2380. W. E. Newton, 66 Chancery Lane, civil engineer. An improved method of producing light for the various purposes of artificial illumination. (A communication.)

2382. A. V. Newton, 66 Chancery Lane, mechanical draughtsman. Improved machinery for printing from engraved plates. (A communication.)

2384. J. J. Potter, 3 New Bridge, Dover. Improvements in upright pianofortes.

PATENTS APPLIED FOR WITH COMPLETE SPECIFICATIONS.

2386. M. A. F. Mennons, 24 Rue du Mont Thabor, Paris. Improvements in smoke-consuming furnaces. (A communication.) *Dated August 8, 1862.*

2387. M. A. F. Mennons, 24 Rue du Mont Thabor, Paris. An improved assorting apparatus applicable to the numbering of raw silks. (A communication.) *Dated August 28, 1862.*

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

1211. P. R. Drummond. Rake.

1307. H. Juhel. Wheels. (A communication.)

1309. E. Ormerod and C. Schiele. Apparatus for cutting or dressing stones.

1311. J. M. Herdevin and J. A. Jullien. Sluice cocks.

1318. J. Fowler. Engines for hauling agricultural implements.

1321. J. & T. Mellodew and C. W. Kesselmeyer. Looms.

1322. C. Schlickeysen. Machinery for moulding bricks.

1323. J. Heyworth. Looms.

1325. A. Williams. Form or seat.

1327. L. G. Perreaux. Clocks.

1329. T. Wilson. Armour plates for ships of war.

1331. T. F. R Brindley. Travelling and other flasks.

1335. R. Burley. Using ordnance under water.

1337. J. Roscoe. Lubricator.

1344. R. Mills. Washing, wringing, drying, and mangling machines.

1347. P. Chenaillier. Concentrating liquids.

1351. W. Greaves. Stirrup bars.

1354. W. Clark. Printing apparatus. (A communication.)

1360. P. H. Colomb. Apparatus for signalling.

1361. T. Markland. Wearing apparel.

1364. N. Wood and J. Stockley. Grinding, smoothing, and polishing plate glass.

1367. R. A. Brooman. Swings. (A communication.)

1369. G. T. Bousfield. Applying steam power to tilling land. (A communication.)

1382. G. C. Grimes. Cigar lights, splints, matches and tapers, or vestas.

1398. F. J. Bolton. Telegraphing.

1399. F. J. Bolton. Displaying the lights in lighthouses.

1406. J. T. Cooke. Battens used in weaving.

1435. P. M. Lopez. Sowing wheat or other grain.

1467. J. Dicker. Delivery of bags or parcels from railway trains.

1907. J. Hartshorn. Lace.

1940. W. M. Williams. Distillation of coal and peat.

1983. W. F. Reynolds. Watch pendant.

2075. W. Clark. Pomade or balsam. (A communication.)

2128. H. Bollinger. Ship building.

2221. F. M. Jennings. Coating ships' bottoms.

2267. J. Cooper. Valves and buckets for pumps.

2337. G. Davies. Governors for steam engines. (A communication.)

The full titles of the patents in the above list can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list who have given notice of their intention to proceed, within twenty-one days from the date of the *Gazette* in which the notice appears, by leaving at the Commissioners' office particulars in writing of the objection to the application.

LIST OF SEALED PATENTS.

Dated September 5, 1862.

604. J. Barker.

607. J. G. Shipley.

612. J. Fowler, D. Greig, and R. Noddings

613. T. Ball, W. Ball, and J. Wilkins.

616. R. Restell.

617. T. H. Wood.

619. A. W. Williamson.

621. G. Edmonson.

622. A. Blair.

625. W. Paterson, W. A. Sanderson, and R. Sanderson, junior.

626. J. Deane.

628. P. J. Guyet.

631. W. Palmer.

640. R. A. Brooman.

641. W. Parker and G. H. Batman.

642. W. Spence.

646. A. Barclay.

648. J. T. Calow.

652. J. Nadal.

656. O. & J. Kerautret.

657. E. G. Camp.

658. C. Hall.

659. T. B. Wilson and W. Wilson.

662. G. Davies.

670. J. Johnson.

671. W. Conyers.

674. A. M. A'Beckett.

701. A. Quinard.

710. W. Turner.

717. W. M'Adam.

718. J. Hunter.

721. S. N. De la Haye de Barbezières.

731. L. P. Mongruel.

* Disclaimer and Memorandum of Alteration.

Note.—Specifications will be forwarded by post from the Great Seal Patent Office (publishing department) on receipt of the amount of price and postage. Sums exceeding 5s. must be remitted by Post Office Order, made payable at the Post Office, High Holborn, to Mr. Bennet Woodcroft, Great Seal Patent Office.

THE
MECHANICS' MAGAZINE.

LONDON, FRIDAY, SEPTEMBER 19, 1862.

ENGINEERING SUMMARY.

THE gigantic scheme of the Canal of Suez is likely to be a perplexing one. Even now, while the works are in progress, it is considered by some to be very doubtful whether the enterprise will succeed, in consequence of the political and engineering difficulties which it involves, the vast expense attending it, the extension of time required for its completion, and the little prospect which the shareholders have of ever making it remunerative. An opinion has, indeed, been expressed, which, though a melancholy one, seems to all probability likely to be correct—that the present generation will not witness the completion of this grand undertaking. The canal which is to extend across the isthmus from Suez to Port Said on the Mediterranean, is intended to be 91 English miles long, and from 260 to 320 feet in width, its depth being everywhere 26 feet. The alimentary canal connects the chief canal with the Nile, and this portion of the work supplies the means of conveying the requirements of the contractors in the execution of their work. This canal is a double one, and consists of a provisional canal, 5 feet broad and 2 or 3 feet deep, while the proper canal of the valley is intended for navigation and irrigation, and is about 16 feet wide by 3 or 4 feet in depth. These two run side by side. At the Lake Timsali the alimentary canal is joined by the great ship canal, which is surrounded by a large number of extensive storehouses and workshops. Here the number of houses and buildings for the workmen have given the locality the aspect of a town, and churches and a bazaar, &c., have also been erected. It appears, though the width of the work has been considerably reduced, it will be about 180 feet wide, but 91 feet only have been at present excavated. Through the ridge of sand a passage has been cut, which, when widened, will form the entrance to a harbour about to be formed in the lake. A report recently published of a visit to these works by Mr. Percy Badger, informs us that "an embankment and an unfinished quay exists at "one side of the entrance to the harbour," and that only 150 yards of the eastern pier have as yet been built, although there are to be two of them, which it was proposed to project somewhere about 7,550 feet. The pamphlet strongly condemns the "insignificant results" which have accompanied the labour of three years in this gigantic scheme, and the expenditure of two-fifths of the company's capital. The success of the canal seems to tremble in the balance, and the tremendous outlay required will, in our estimation, go far to make the project an unsuccessful one.

The meeting of the Royal National Lifeboat Institution was held last week, and the monthly report, recorded the interesting fact of the inauguration of a new lifeboat at Withernsea, near Hull, which was witnessed by upwards of 20,000 persons. Not the least important item was the account of the visit of some French officers to the society's stations on the north-east coast, as it drew from them an expression of their sincere admiration of the working of this humane institution. We believe there are 122 lifeboat establishments, and a large amount of money is annually laid out upon them. The society is evidently worked well, and deserves the support of the public.

We have more than once had occasion to call the attention of the Admiralty and ship-owners to the auxiliary rudders invented by Mr. W. R. Malley, of Plymouth. These rudders are placed under the water-line, and consequently secure from shot. When not used they fit into a recess in ship's side, and therefore avoid offering any resistance to the ship's progress, the outer side of the rudder being on a perfect level with the ship's planking. A trial of the rudders has recently taken place in Plymouth Sound, on board of a small paddle-wheel steamer, to which one of the rudders was fixed for temporary purposes. Several naval officers were present to witness the trial, the result of which proved that the rudders are quite able to steer a ship, provided the main rudder should become disabled. The inventor considers that he should be enabled to turn a vessel, with the assistance of his rudders, in about half the time that is now consumed for that purpose.

On Friday last a trial of Mr. Wm. Roberts' fire-engine took place at Hodge's Distillery, Lambeth, in the presence of several scientific gentlemen and others. Upon 150 of pressure being obtained, the engine was propelled into the middle of the yard, and turned around a little over its own length in three seconds. Mr. Hodges and Mr Roberts then mounted the engine, and took it out of the yard and down Church-street, as far as the Railway arch, and brought it back again into the yard in three minutes. The engine was then taken to the water and worked, and a one and three-eighths jet of water was thrown 140 feet perpendicularly, and 184 feet horizontally, with a stiff breeze blowing at the time. Several other experiments were made with various size jets, showing that the engine could be used from its maximum quantity to about one gallon per hour. The result of the trial was satisfactory.

It can now be calculated with tolerable certainty that the International Exhibition will not pay. No doubt there are many causes for this. One is the many blunders of the Commissioners in the first place, what shook confidence in so many minds. Another, and no doubt a greater cause, is the distressed condition of the country. It appears that the large attendance during September 1851 will not be paralleled this year. The Exhibition will remain open throughout October, and be formally closed on 1st of November. At that time it is supposed the deficiency will amount to about £25,000. It appears that about £400,000 have been taken up to the present time. The guarantors, who came forth so liberally in the first place, need not, however, be under any apprehension, as Messrs. Kelk and Lucas, the contractors, have expressed their willingness to make an arrangement which will relieve the guarantors of any loss.

Our railway traffic is ever on the increase. As the weekly returns are made, we find that there is a very considerable difference in the amount of traffic over the corresponding period of the past year. And especially has it been so during the present season of 1862, when the International Exhibition has brought daily to the great metropolis its thousands. Last year, an average day's work of the railways of the United Kingdom was to carry 500,000 passengers, 258,000 tons of minerals and merchandise, 35,000 live stock, 1,100 dogs, and 740 horses. But during the present year, although it is not possible to give the exact number, in consequence of the companies keeping no record of the journeys of season-ticket holders, yet it may be fairly stated at six times the population of the whole of the United Kingdom. The trains (including the goods trains) travelled 2,897,748 miles more in 1861 than in 1860, which is equivalent to going round the world 116 times more last year than in the year before; but we shall doubtless find, when the time for the preparation of statistics for the present year shall have arrived, that even this number will pale before the increase of 1862. We are told, even, that nearly four million trains ran in the course of the last year, which would make an equivalent in a day of more than seven times the number of minutes in one day. Some idea also of the enormous amount raised by railway companies, as gross receipts, may be gained from the fact that the sum for the past year considerably exceed the interest of the National Debt, and amounted to about 8 per cent. on the capital. As the amount of traffic increases, so unfortunately, with few exceptions, does the number of accidental deaths and injuries. Thus while in 1860 the number was 509, in 1861 it increased to 827; but there was an exception in the years 1858-9, when the corresponding returns showed a decrease of about sixty. These returns, however, only apply to the passengers who met with their deaths or accidents from causes beyond their own control. Last year the sum of £131,062 was paid as compensation for personal injury. It must, however, be remembered that very serious and lamentable accidents on the Brighton and other lines would make this number considerably higher than the year previously.

A very interesting steam-plough trial took place on Saturday last in a field of 35 acres, on the farm of Mr. Collinson Hall, of Navestock, Essex, in order to test a new rope, or properly speaking, a chain, of a new construction, lately invented by Mr. Hall. A very powerful engine, built on Mr. Charton's principle, was used on the occasion. The steam was maintained at a pressure of 150-lbs. (the boiler being capable of standing a pressure of 360-lbs. per square inch.) The plough used was one of Fowler's ordinary four shares and the width of the field was about 160 yards. The winding drnm of the apparatus, which is made to correspond with the form of the chain, was mounted, as usual, beneath the engine. The drum consists of iron segments, each segment having two sides, one being longer than the other. The chain or rope is made out of a series of bars, with an eye at each end; to these eyes short links are attached by rivets. The space in the links between the ends of the bars is occupied by a tongue when travelling round the drum. By the use of the tongue a powerful grip is given to the rope, to enable it to propel the implement. Many advantages are obtained by this invention. It does not require the rope to be wound once or more round the drum to get a purchase, as in the case when a wire rope is used. Another advantage is that the giving off and taking on the rope is in the same line, and can therefore be brought into a position so as to keep the rope parallel with the ground, and so securing a direct pull upon the implement. The work performed at the trial gave great satisfaction, and we expect ere long to see Mr. Hall's improvement applied to all steam tilling operations.

OUR NAVAL ARTILLERY.

SOME important and interesting experiments were conducted on Tuesday at Shoeburyness, in the presence of the Lords of the Admiralty, and the members of the Plate and Ordnance Select Committee, with the celebrated monster gun made in the year 1855 by the Mersey Steel and Iron Company. The calibre of this gun is thirteen inches, and its weight about twenty-two tons. The solid spherical shot weighs 286 lbs. and the powder charge em-

ployed on this occasion 74 lbs. The "Warrior" target, against which the practice was carried on, was a mass 12 ft. by 10 ft., of 4½-in. armour plates, bolted to 18 inches of solid teak, in beams of 9 in. thick, laid transversely. One shot only was fired, which made, at the distance of 200 yards, a clean hole two feet square, right through the armour plates, wood backing, supporting ribs, and buried itself in the heavy timber supports of the target. The ascertained velocity of the projectile was 1,630 feet per second. The effect upon the target was so prodigious that no question can be entertained that even at a thousand yards the side of the "Warrior" would be penetrated with perfect facility. The next experiment proceeded with, was a test of Mr. Whitworth's 12-pounder breech-loading gun, at iron plates two inches thick, with solid steel projectiles, and hollow steel projectiles, filled with powder, but without fuze of any kind. The object of the experiment was to determine whether the result of the impact of a flat-ended steel projectile upon an iron plate at a short range would not evolve sufficient heat in the metal of the projectile itself as to ensure the ignition of the powder within the shell, after having passed through the iron plate. The gun was placed at a distance of one hundred yards from the target, and the solid projectiles having penetrated the two inches and two inches and a-half of iron, the shells were next tried, with a charge of one pound fourteen ounces of powder: the projectile itself holds six ounces of powder. The second shell burst, after passing through the iron and timber, slightly shattering the timber balk supports, but proving the question of the generation of heat in a sufficient quantity to ignite gunpowder, as had been previously determined in 1854, by the Ordnance Select Committee at Woolwich, when testing Mr. Lancaster's wrought-iron shell, at masses of granite.

Mr. Whitworth's 70-pounder was next tried. The target was constructed of one armour plate four inches thick, bolted upon an oak frame nine inches thick, attached by a side framing to a back of oak four inches thick, covered on the back by a plate of iron two inches thick; the interval between the front and back frame was about thirty inches, the target being intended to represent the side of a ship. The shell weighed nearly 70 lb., and the charge of powder employed was 12 lb. The gun was placed at 200 yards from the target. The first shell fired passed clean through the four-inch plate, as well as the timber backing, striking violently against the two-inch plate in the rear, which it bulged out and cracked nearly four inches, and then burst, shattering the timber box to pieces. Had it not been for the two-inch plate in the rear, the bursting would have taken place outside the target, after passing through, and therefore without material damage to the side of a vessel constructed with plates four inches thick.

Very different, indeed, must be considered the effects of the wonderful Horsfall gun. Where that struck, everything was driven resistlessly before it. The effect of the 70-pounder Whitworth on the iron plates was a hole about four inches in diameter, punched clean out, without any fracture of the surrounding portions of the iron. Where the projectiles from the Horsfall gun struck the iron, not only was a huge hole two feet square struck out of the mass of the plate, but the surrounding iron cracked and riven in all directions—a complete wreck in fact. This gun has opened up a new era in the construction of ships, and the arrangement of our defences.

From time to time our columns have been devoted to the discussion of this most important and interesting subject. Step by step we have examined and discussed the great Armstrong experiments, and we felt it our duty to express our unhesitating opinion of the unsoundness of Sir William Armstrong's propositions, and, as our readers are fully aware, entered at very considerable length into the reasons upon which our judgment was founded.

Day by day we find our opinion verified and sustained; and it will be observed, from the above results of the trials at Shoeburyness, that the Horsfall gun successfully accomplished that which Sir William Armstrong, with the whole resources of the nation at his command, has been, after numberless trials, unable to accomplish. And yet this gun has been in the hands of our government for six years, and all trials steadily and pertinaciously refused until it could no longer be denied. Where is the influence, of what nature, and why exerted, that should so compel the War Department into one particular channel? We fear very much that this will never be known until the real parties to the great Elswick monopoly are known to the country. One thing is clear, the results of these trials cannot fail to urge the Government to a more honorable course of action towards those gentlemen who have devoted for so many years their time, talents, and energy to the service of the country; and we doubt not that even the official mind will have to admit that the officers of the War Department have perpetrated a serious error of judgment in making an unwise contract, and spending three millions of public money uselessly.

SUBSTITUTES FOR COTTON.

It has been again and again stated that the American war will bring one blessing in its train—that of directing the attention of England to other fields for her cotton supply. New companies have been started for the purpose of promoting the growth of cotton in India, Jamaica, and Africa; and other companies are likely to be established for producing the article in Algeria, in Turkey, and other places. In fact, there is scarcely a warm part of the world where cotton may not be obtained in abundance. A correspondent states that cotton grows spontaneously in Cochin-China, and that it is in the power of France to obtain from that region sufficient of the commodity to render her independent of foreign supply. It appears that the growth of the cotton is not confined to merely one province, but that the entire country is suited to its production. The cotton grown in Cochin-China is said to be soft and silky; and, though but little attention has hitherto been devoted to its cultivation, it rivals in quality the produce of New Orleans. After a two years' war, Cochin-China has alone exported 2,000,000 lbs. weight of cotton.

It is not, however, in finding new regions for the production of cotton which excites curiosity, but in finding substitutes for that material. On Monday last a letter appeared in the "Morning Star" from Mr. F. Fenton, Mappleton, Derbyshire, calling attention to the writer's process for converting jute, rhea-fibre, hemp, flax, tow, China grass, &c., into a substance capable of substituting cotton, and of being spun by the same machinery. The writer of the letter enclosed a sample made from Russian hemp. He says: "From flax, or China grass, a fibre-cotton of the greatest strength and fineness is produced, and I may add that the cost of conversion is merely nominal and very rapid, and requires little machinery, and that of the simplest kind."

On the following day the "Star" offered some comments on the sample of fibre-cotton enclosed by Mr. Fenton. It says:—"It is, in appearance, about as much like cotton as sawdust is like wheat flour. It is in colour rather brown than white. It is rough, hard, and brittle. Its fibres are thin but short. It has no soft down clothing and intertwining with its threads. It is, in fact, a woody rather than a woolly substance. The process to which it has been subjected has no doubt effected a considerable change. Neither rhea, nor hemp, nor jute, nor China grass could have been made to yield such a material by any of the arts known to our chemists or manufacturers. Flax cannot be beaten into fibres thus fine, nor steeped in any liquid with which we are acquainted until thus intermixed. Mr. Fenton is certainly in possession of a secret which it must have cost much ingenuity to discover; and if cotton had disappeared from the earth his secret might be as valuable as it is curious. We have no doubt that the yarn which has been spun from the material of which he has sent us a sample has its uses. It may compete with flax. It may be wrought up into a coarser and stronger sort of linen. It may serve to mix with wool or silk in the various fabrics in which those substances enter. But it is too unlike cotton to be used as a substitute for it in machinery which cannot easily be re-adapted to unusual descriptions of that article."

It is so far encouraging to know that if the war in America continues to desolate that continent, and if other parts of the world cannot be rendered so prolific of cotton as they have so frequently been represented, substitutes may be obtained to answer some of the purposes of that article.

But this is not the only substitute for cotton which has recently occupied the attention of many most interested in the question. Some letters have been just published by Messrs. Phillips and Son, of Abchurch-lane, which go to show that another discovery or invention has been made; and the inventor himself steps forward and says that he firmly believes that he shall be able to establish—1. That his substitute will answer all the purposes of cotton; 2. That a present and sufficient supply can be procured and the operatives at once set to work; 3. That the future supply of the material may be obtained by cultivation in the United Kingdom, without displacing one acre of land from other purposes; and thus be the means of developing a new staple industry for the country. This appears almost too good to be true. But the writer is most unreserved in the matter, which a committee has been formed to investigate. It is said that manufacturers, and other gentlemen capable of judging, have passed a very favourable opinion on the material, and that many persons practically interested in the cotton question have visited the counting house of Messrs. Robertson and Fleming to see "the patent prepared jute," and have admitted that it is well adapted for use, and that by being made with the fibre or staple shorter, it can be readily mixed and spun in the cotton machinery. There appears to be no difference of opinion on the adaptability of the material being mixed with wool. We shall watch with some interest this investigation.

We find from an article in the "Nord" that a French captain has just returned from Africa with specimens of a plant, the name of which he keeps a secret, and which, when subjected to some chemical process, yields a substance perfectly resembling cotton. Several specimens have been woven from this material and presented to the Emperor of the French. It

is said that these stuffs are stronger than cotton tissues, equal in fineness, and 60 per cent. cheaper. The plant abounds in Africa and America. A company is being formed to produce this substance. This is only a newspaper report, and should be accepted with considerable caution. There is, however, considerable satisfaction in knowing that endeavours are being made in many directions to open up new fields for the cultivation of cotton, or to produce substances which will answer, to some extent, its purposes.

BREAD-MAKING BY MACHINERY.

THE question of making bread by machinery is now attracting attention, and well it should, considering the importance of the subject. There can be no doubt that many of the bakeries of the metropolis are in a scandalous condition. Mr. Tremenheere, in his report on the subject, recently published, says, "In about "half the total number of the bakehouses "visited by me I found not only the ventilation "very defective, but the state of dirt beyond "what I had been led to expect." Though Mr. Tremenheere's report has been, in some of its features, contradicted by some correspondents, it has been substantially confirmed by others. One correspondent who signs himself "Home-Made," says, "Some years since I "lodged with a baker (not in London), and "was so thoroughly set against bakers' bread, "that I seldom ate a mouthful, and when I do "it is under exceptional circumstances, and as "sparingly as possible. I have seen cock-"roaches and crickets in swarms crowding the "kneading-trough; and one morning, hap-"pening to pass through when the men were "making the dough into loaves, I saw the "knife of one cut through two mice in the "space of three or four minutes, and cock-"roaches were pretty thick. The man told "me it was of nightly occurrence, and that "neither cats nor mice were of much use in a "baker's shop." These, however, are not the only sources of dirt in a baker's shop. Some correspondents speak of sweat, of sore arms, and many other disagreeables. We must make our allowance for exaggerations in this as in most other questions. No doubt it is supposed to be to the interest of inventors of bread-making machines, if not to misrepresent matters, at all events to magnify the objectionable features of the present system of baking. But Mr. Tremenheere is above suspicion, and what he has reported is sufficient to arouse public attention on the subject.

Now that we have machinery applied to washing, cleaning knives, boots, and other domestic necessities, it is a little surprising that machinery has not been more successfully applied to bread-making. We have heard a great deal about the over-worked and oppressed journeyman baker, his pale face, and the stern necessity he labours under to turn night into day; and when the vast amount of bread daily made in the metropolis is considered, it becomes a legitimate subject of enquiry why manual labour has not been more extensively superseded by machine work. One patented invention—that of Mr. Stevens—has been advertised and paraded before the public to a considerable extent, and a company has been formed to promote its manufacture and use; but, either from its inefficiency or dearness, it is certainly not much used by bakers. It has been recommended, testimonialized, and patronized, but the trade do not manifest any particular partiality for it. One correspondent who approves of the machine says, "The pe-"cuniary position of bakers generally renders "them unable to bear the expense of putting "up a machine, which, to be complete, costs "nearly £100." Another correspondent, "A "Journeyman Baker," denies that the machine is any saving of labour—"that whilst there "were four doughs made every night, only "one was made by the machine, the other "three being made in the usual way; and so "hard did the men find the work that they "would have been glad not to have used the "machine at all; but, as the bread was adver-"tised as machine-made, master insisted on "some being made in that way." The publication of this letter brings the "master" into print, but as he acknowledges that he has become a director of the company formed for manufacturing and selling Stevens' machine, we must be a little cautious in receiving his testimony. But whether Mr. Stevens' machine be efficient or not, or whether it is superior to that invented by Mr. Vickers, we shall not stop to enquire, but it is quite evident that neither machine is very much used. We have always considered that the price of bread-making machines, and particularly that of Mr. Stevens, stood in the way of their general adoption.

This, then, is an important question for inventors and manufacturers. We see no reason why mechanism cannot be applied to bread-making as to washing clothes. There is no necessity for intricate machinery. The operations involved in bread-making are simple, and can easily be performed; and it is not very creditable to the scientific mind of the age that some cheaper and more efficient method of making the staff of life has not been adopted. It is not only an economical question, but a sanitary and philanthropic one, and we shall continue to agitate it until it is put on a more satisfactory basis.

M. FREMY ON THE PRODUCTION OF STEEL.

AT the sitting of the French Academy of Sciences, held on the 18th August last, a paper was presented on this subject by M. E. Fremy, already well known by his researches on the composition of steel. The following is an abstract of the paper:—

The author commences by observing that steel is destined to play a far more important part in industry than hitherto. It is already employed for rails, axles, tyres, piston-rods, and shafting; the military are thinking of producing cast steel guns, and men-of-war will soon replace their heavy iron plating by a light, elastic, and tough plating of steel. It is evident that those nations who do not strive to keep up with the march of science will very soon be left in a position of inferiority.

France possesses abundance of iron ores of good quality, but fuel is dear and transport still costly; hence the metallurgical methods to be sought for must be such as will reduce the cost of fuel to a minimum, so that good French ores shall form the principal article of expenditure.

The author goes on to enumerate the distinctive qualities of cast iron, malleable iron, and steel, remarking that steel has the good properties of the two other varieties without their objectionable features. It also possesses the power of resisting a crushing force in a greater degree than that we find in cast iron, and double that which is found in malleable iron. It also receives homogeneity by fusion. Hence, cast steel is the best material for any new applications of iron, and the question to solve is, how it shall be obtained in masses of considerable size. The Yorkshire method gives excellent steel; but in this proceeding it has hitherto been only found practicable to fuse it in crucibles holding not more than twenty kilogrammes (forty-four lb.) of steel. Reverberatory furnaces have so far given no results on an important scale. Again, this method requires malleable iron specially adapted for the purpose, and very costly; and, in addition, a large quantity of fuel, equal to six or seven times the weight of the steel obtained. On this system, therefore, France could not successfully compete with England, for to her economy of fuel is of the greatest importance. The author had endeavoured to work with this in view, in order to discover a process in which fuel shall be little required. When he commenced his investigations, it was generally thought that, in order to get good steel, we must go to Sweden or Russia for the proper quality of iron; and it was also considered that the iron must obtain from its ore a sort of steeling propensity. The author had never doubted the importance of this propensity, which is possessed by the iron of the north, but he desired by chemical examination to clear up what was a metallurgical mystery, and to determine the nature of the body which is the real agent in the conversion of iron into steel. Lastly, he wished to find a means by which iron hitherto rejected could be made to furnish steel. He, therefore, went carefully into the subject, with the view of ascertaining the exact composition of steel. It resulted, from his investigations, that carbon was found to be not the only useful element in the conversion, but that other metalloids, as phosphorus and nitrogen, play an important part. He also established the fact that these bodies cannot act properly unless they are present in proper proportions, and unless there is an absence in the iron of any body, such as sulphur, which would paralyse their action. The quality of the northern iron depends on the presence of the particular elements which he had found to be necessary, and cementation completes the number, provided noxious substances are absent. Hence, in order to make steel, it is necessary, by careful refining, to eliminate from the iron the noxious ingredients, and to impart to it those which are wanting. If we use an impure iron, or if we add an insufficient quantity of any necessary element, such as carbon, we are certain to fail.

The author states that he has completely succeeded in his object, and he expresses his obligations to Mr. W. Jackson, the director of the works of Saint Seurin, who placed the resources of his establishment at the disposal of M. Fremy, who was thereby enabled to conduct experiments impossible in a laboratory. While in England he had an opportunity of seeing Bessemer's process once, along with Mr. Brown, his colleague on the jury. Although much struck with the magnificence of the process, it left serious doubts on his mind as to the quality of the steel produced. His colleagues on the English jury maintained that the Bessemer steel tempered irregularly, and could not be compared with ordinary cast steel. He left England with the impression that the cast iron of France, reduced by coke, would contain too much sulphur and phosphorus to be treated by this process; but all his fears were dissipated by his experiments at Saint Seurin. The Bessemer process in twenty or thirty minutes converts cast iron into a kind of burnt or azotised malleable iron, excessively *red-short*. In this condition it cannot be used, but the addition of a small quantity of cast iron, suitably chosen, and which contains the steeling principles, produces steel immediately. Hence, the Bessemer steel is the result of the combination of azotised malleable iron (fused) with a small quantity of cast iron possessing the necessary properties. The malleable iron varies in character with the cast iron from which it is produced. Experiments were made on a large scale, using twenty kilogrammes of material at once, so as to give confidence in the results obtained. It was found, that all iron which can be conveniently refined will give excellent steel when submitted to the requisite conditions.

Their first trials gave steel which would not resist tension. Synthetical experiments led them to improve their means of purification, and to make use of more active means for imparting the steeling properties. The result was that they got excellent steel from French pigs, until now considered incapable of conversion. Several thousand kilogrammes of steel had been thus

obtained. It can be hardened by tempering, and has already been made into various articles, as lathe tools, gravers, knife blades, &c. English workmen who examined the specimens considered them equal to good English steel.

They had thus produced, in twenty-five minutes, with French pig, costing about ten francs the 100 kilogrammes, a cast steel worth 150 francs the 100 kilogrammes; and they had converted into excellent steel varieties of cast iron hitherto not treated by Bessemer's process. Lastly, they had succeeded in obtaining complete fusion of malleable iron, which, therefore, became much more tenacious and also more homogeneous. It could thus be applied to fresh uses.

The author excuses himself for not going further into details, as he could not do so without revealing what he had only learnt in confidence. He observes, however, that in following out the process strict chemical examination of the cast iron is necessary. Each variety requires a special study, in order to ascertain what ingredients it possesses, and in what it is deficient. Chemical analysis is, therefore, the only true guide. He concludes by anticipating a great revolution in the metallurgy of iron from the facts here indicated, and it will be one which will place France in a more advantageous position than heretofore.

IMPROVED FLUSHING APPARATUS.

FIG. 1

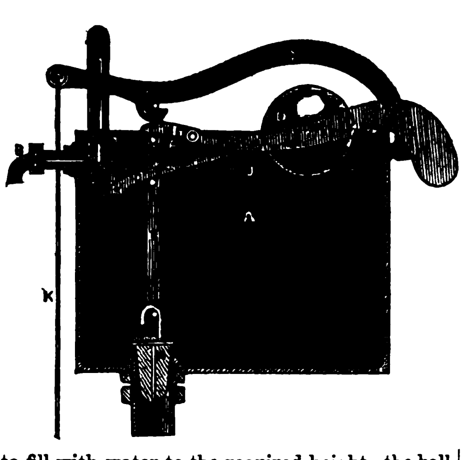

FIG. 2

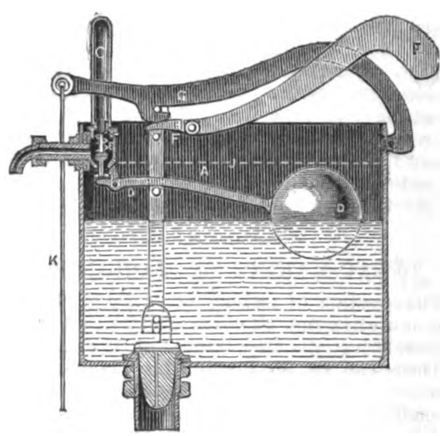


Mr. G. Manwaring, of Southampton, has just patented an apparatus for flushing closets, sewers, and other services, which he describes as follows:

My invention consists of self-acting mechanical appliances, whereby the closet is cleansed after the same has been used, by means of supplying water through a cistern connected to and working with a small supply cock or inlet valve, to which I apply an air vessel, by which means the supply valve can be worked against any pressure with ease and soft action; the large outlet or discharge valve from which is closed, while the inlet valve is opened, and *vice versa*.

The following is a description of one of the methods I adopt in carrying out my invention:—Water is admitted into a cistern through a supply cock or valve fitted to the upper part of the cistern, to which I attach an internal loaded floating ball, which gives power to the ball lever, sufficient to open the valve against any pressure. This connecting lever to the valve is regulated by a connecting rod having adjusting stops and pins in it, which causes a proper pause of time in the action in the opening and shutting of the supply and discharge valves, causing them to be worked with the greatest accuracy; the lower end of this connecting rod is jointed to the discharge valve; in the middle of the rod the lever of the floating ball works, and the upper end of this rod is jointed to the working lever, which takes its fulcrum from the end of the cistern at that part of this lever where it is attached to the connecting rod; the under part of the joint is acted upon by a lifting arm on the weigh or weighted shaft, which is provided with guides for the connecting rod; the lifting arm raises the working lever, and the connecting rod, by means of the counterweight, after the same has been kept down by the closet being occupied, during which time the cistern is filling with water; by this motion it cases the supply valve to close and the discharge valve to open.

The particular formation of the moving joints or bearings which I apply avoids the necessity of bolts, screws, or joint pins, rendering the general application simple, cheap, and durable, and the supply cistern cannot be affected by the frost, it being only charged during the time the closet is occupied.

When the apparatus is applied to work self-acting, it is thus the closet seat may be hung on pivots or hinges, or othewise, competent to allow the same to decline about three-quarters of an inch. When the closet is occupied by a person, it is thus kept down:—The connecting chain or wire from the seat presses the end of the working lever down, which closes the discharge valve and opens the supply valve, and allows the cistern to fill with water to the required height; the ball then floats, which causes the supply valve to shut; all then remains stationary until the person leaves the closet seat, which then rises again to its original height by means of the spring or weighted lever, and the counterweigh or weighted shaft then raises the working lever and the connecting rod which opens the discharge valve, and the supply of water in the cistern descends through the down pipe to the pan of the closet, which flushes the soil away to the sewers.

My invention may also be applied without being made to work self-acting, that is to say, the chain or wire from the working lever may be worked by hand, then the mechanical appliances in the cistern will work the same as before mentioned.

My invention will be found especially adapted to high-pressure, as all waste of water will be effectually prevented and no leakage is likely to occur; it may also be applied with low pressure; the size of the cistern may be varied to suit circumstances; I find, however, that one of the capacity of about one and a-half gallons is sufficient to supply an ordinary water-closet. In the drawings hereto annexed I have represented a cistern constructed and fitted with the mechanical arrangements according to my invention.

Figure 1 is a section, showing the cistern empty and the fittings in their respective positions, the supply valve being closed and the discharge valve open; Figure 2, a similar view, representing the cistern filling with water and the fittings in their respective positions, the supply valve being open and the discharge valve closed. Similar letters of reference indicate similar parts in both figures.

A is the cistern; B B the inlet or water supply valve to the cistern; C the air vessel for the supply valve; D D the loaded floating ball and lever; E the connecting rod which regulates the working of the ball lever; the rod at the top end is attached to the working lever G, and the lower end to the discharge valve H, for the purpose of opening and shutting the same; F F F the weigh or weighted shaft, the working arm or lever of which passes through the connecting rod E, near the top part thereof, for the purpose of guiding the rod E, and working against the under part of the joint of the working lever G; G G G the working lever, the fulcrum of which vibrates in a hole at the end part of the cistern; H the discharge valve; I I the brass seat of the discharge valve, with union joint to connect the discharge pipe; J J the water line of the cistern when full; K the connecting chain or wire from the lever to the closet seat, or from the lever for hand-pull.

STEAM-BOILER EXPLOSIONS.

The Decomposed Steam Hypothesis—The unsatisfactory results generally obtained by those who have sought to decompose water by heat on a large scale, with the view of applying its elementary gases separately, does not appear to have prevented the occasional adoption of the hypothesis that, in certain cases, all the steam contained within a boiler is decomposed, and its hydrogen (by some means not easily explained) exploded with great violence. That steam, passed over pure metallic iron heated to redness, is decomposed, is perfectly true, although the iron must retain all the oxygen separated in the operation. With oxidised iron, however, the process of decomposition cannot be continued. This is, we believe, a chemical fact of which there can be no dispute. To decompose 1 lb. of water (or steam, which is chemically the same substance) 14·2 oz. of oxygen must be fixed by the iron, and only 1·8 oz. of hydrogen will be set free. This large proportion of oxygen, absorbed by only a few square feet of over-heated surfaces, would soon form an oxide of iron of sufficient thickness to arrest all further decomposition, and all the hydrogen up to that time disengaged would not amount, perhaps, to 1 lb. in weight. By itself, or mixed with steam, hydrogen cannot be exploded, nor even ignited. It will extinguish flame as effectually as would water.

Upon this subject we may refer to a report made by Professor Faraday, in May, 1859, to the Board of Trade, upon the liability to accident consequent upon the introduction of an apparatus for superheating steam on board the Woolwich steamboats. In this apparatus the steam was carried in iron pipes immediately through the furnace, and in contact with the incandescent fuel. Professor Faraday, after having examined the apparatus at work, says:—

"I am of opinion that all is safe, *i.e.*, that, as respects the decomposition of the steam by the heated iron of the tube, and the separation of hydrogen, no new danger is incurred. Under extreme circumstances the hydrogen which could be evolved would be very small in quantity—would not exert greater expansive force than the steam—would not with steam form an explosive mixture—would not be able to burn with explosion, and probably not at all, if it, with the steam, escaped through an aperture into the air, or even into the fire-place.

"Supposing the tubes were frequently heated over-much, a slow oxidation of the iron might continue to go on within; this would be accompanied by a more rapid oxidation of the exterior iron surface, and the two causes would combine to the gradual injury of the tube. But that would be an effect coming under the cognizance of the engineer, and would require repair in the ordinary manner. I do not consider even this action likely to occur in any serious degree. I examined a tube, which had been used many months, which did not show the effect; and no harm or danger to the public could happen from such a cause."

Professor Taylor, of Guy's Hospital, reported in part, as follows, upon the same apparatus:—

"It is true that steam passed over pure metallic iron heated to redness (1,000 deg.) is so decomposed that the oxygen is fixed by the iron while hydrogen gas is liberated. This chemical action, however, is of a very limited kind. The surface

of the iron is rapidly covered with a fixed and impermeable layer of the magnetic oxide of iron, and thenceforth the chemical action is completely arrested. If the interior of an iron pipe has been already oxidised, by passing through it, while in a heated state, a current of air, there will be no decomposition of steam during its passage through it. If the interior of an iron pipe were not thus previously oxidised, it would speedily become so by the oxygen derived from the air, which is always mixed with steam. Hence, chemically speaking, under no circumstances, in my opinion, would any danger attend the process of superheating steam as it is conducted under this patent. It is proper, also, to state that hydrogen is not explosive, but simply combustible, and, assuming that it was liberated as a result of the decomposition of superheated steam, its property of combustibility would not be manifested in the midst of the enormous quantity of aqueous vapour liberated with it and condensed around it. There could be no explosion, inasmuch as hydrogen, unless previously mixed with oxygen, does not explode; and oxygen is not liberated but actually fixed by the iron in this process. It is a demonstrable fact that the vapour and gas evolved under the form of superheated steam tend to extinguish flame and to prevent combustion from any other cause."

Professor Brande, in a report made by him to the patentees of the same apparatus, observes:—

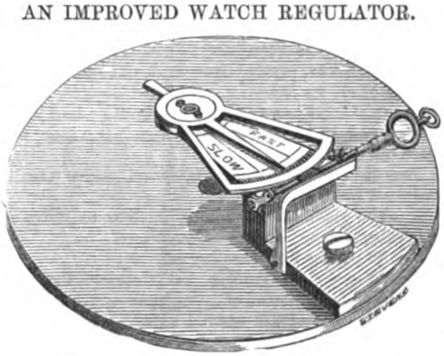
"In reference to the question which you have submitted to me, respecting the possible or probable evolution of hydrogen gas, and consequent risk of explosion in the processes, and by means of the apparatus which you employ for the production of superheated steam, I am of opinion that there can be no danger from such effect—that the temperature to which the iron pipes connected with your boiler are raised, and the extent of the iron surface over which the steam passes, are insufficient for its decomposition; and that, if the temperature of the pipes were even raised considerably beyond that which you employ, or would be able to attain, a superficial layer of oxide of iron would line the interior of the heated pipes, and so prevent any continuous decomposition of water. Effectually to decompose steam, by passing it over iron, it is necessary that a very extended surface of the metal (as in the form of thin plates or iron turnings) should be used, and that the temperature should be continuously maintained at a bright red heat, namely, at a temperature considerably above 1,000 deg. F. I have read Dr. Taylor's report, and entirely agree with the inferences he has drawn as to the absence of danger from the evolution of hydrogen gas in practically carrying out your process for the production and application of superheated steam."

The practical conclusions upon this subject are the following:—1. Decomposition cannot possibly occur, to any considerable extent, under any circumstances arising in the working of ordinary steam boilers. 2. If it did occur, the hydrogen thus liberated would have no access to oxygen, without which it could neither inflame nor explode. 3. Even if oxygen were present, the presence of steam would prevent ignition. 4. If oxygen were present, and no steam existed in the boiler, the hydrogen would only inflame and burn silently as fast as it was produced, the heat for ignition being supposed to come from a red-hot plate. Under these accumulated impossibilities of violent explosive action, the explanation of boiler explosions by the decomposition of steam is without any support whatever.—*Chemical News.*

GARDENS ON HOUSE-TOPS.

AN Edinburgh paper says:—"In a tall block of building in the Pleasance, Edinburgh, a curious and novel arrangement—that of converting the roof of the house into a bleaching-green—has been carried out. In the roof, which is of course flat, the first requirement is, that it should be water-tight. To secure this, the sole is constructed of thick iron plates, rivetted together at the flanges, and having india rubber introduced in the manner of a 'washer' between the edges. To resist corrosion, the iron has been treated while in a heated state with oil, which it is expected will act as a preservative of the metal. Over the joints of the plates asphalt has been poured, so as to assist in preventing the access of damp to the house below. Next the iron a thin layer of clay is placed, above which soil is laid, making a thickness of twelve inches from the iron to the top of the turf. The 'green' is divided by walks of asphalt, so as to preserve the turf, and at the same time to give access to all parts of it. Round the sides the edges of the iron plates are turned up to the extent of 14 inches, so that continuous rain to that depth must fall before the water can run over the walls, supposing all drainage and evaporation to fail. At the front and back, a parapet of one foot in height, carrying an iron railing of five feet, will afford complete protection, the ends being protected by the chimney stacks. A portion of the roof is occupied with a large water cistern, composed of iron, double-cased, with sawdust between, to prevent the action of the sun and of frost from affecting the water. The staircase by which the roof is reached is covered with a tall hutch, on the outside of which a ladder and gangway afford access to the chimneys. Notwithstanding the quantity of iron used in the roof, the weight of the structure is comparatively light. The pressure is vertical instead of outward, as in a sloping roof, and the partition walls throughout carry their share of the weight. The plates have a bearing of 14 inches on the front and back walls, and are sunk four inches in the gables, thus giving abundant support on all sides. The idea of utilising the roof in this way is entirely new, and should the present experiment stand the test of time, the plan will probably be adopted in other cases."

AN IMPROVED WATCH REGULATOR.



THE above engraving illustrates an arrangement for moving the regulator of a watch or other time keeper by means of a key of the ordinary form. This arrangement is patented by Mr. N. Wighton, watchmaker of Edinburgh. A quadrant is attached by arms to the ordinary regulator hand, the outer edge of the quadrant is toothed and geared into by a worm on a spindle, which is acted on by the key, as shown. The regulator hand is caused to move to or fro, according to the direction in which the spindle is turned. A spring entering the teeth of a ratchet wheel on the spindle retains the regulator in the position at which it was set until the spindle is again turned.

The mechanical arrangements for fitting and fixing the armour plates of the "Prince Consort" at Pembroke dockyard are completed. These arrangements, which have been devised and carried out under the superintendence of Mr. J. Inman Fincham, the master shipwright of the yard, provide for an extremely economical system of work, and have been warmly commended by the Board of Admiralty. Tramways have been laid down from the landing wharf to the ship's sides, and to the machine-house, and steam cranes for raising and lowering the plates have been placed upon them on wheels, so that the huge plates, weighing several tons each, can be transported from the wharf either to their places on the side of the ship, or to the machine-house and back again in a very few minutes. The machine-house contains numerous well-selected machines for bending, planing and drilling the plates, and furnaces for annealing them when necessary.

ON THE CHEMICAL EXAMINATION OF IRON SAMPLES, AND OF THE MATERIALS EMPLOYED IN THEIR MANUFACTURE.*

By F. A. ABEL, Esq.,
Chemist of the War Department.

IN conducting a large series of analytical examinations of a quantitative character, which have been undertaken, not simply to furnish results of scientific interest, but with a view to be of use in considerations of a practical character, it is not only admissable but necessary that some discrimination should be exercised in determining the extent of detail of such examinations, so that, on the one hand, a proper knowledge be obtained of the proportions of all the important and characteristic components of a substance, while, on the other hand, no great unnecessary expenditure of time and labour be incurred in researches on the existence or proportions of constituents which occur in minute quantities in the substances examined, and have not yet been discovered to exert any influence on its chemical or physical character.

Thus, the existence in cast iron of metals, such as titanium, calcium, magnesium, nickel, copper, lead, &c., has been traced by minute analyses of various samples by different chemical authorities, and the proportions in which they occur have also frequently been determined; but it is only when some foreign metal, such as copper, lead, or arsenic, has been found to exist in a sample of cast iron in a larger proportion than usual, that it has been proved to exert some marked and well-established influence over the character of the metal.

It may, therefore, be safely inferred, in the present state of our knowledge, that modifications in the properties of cast iron are not dependent upon the presence or absence of minute proportions of such foreign metals, and that researches having in view the discovery or the determination of the proportions of these constituents, do not at present possess any practical interest, and are only advisable:

1. In conducting analyses of specimens of peculiar interest for purposes of scientific record.
2. In undertaking special researches with a view to ascertain whether, and to what extent, these constituents influence the properties of cast iron.

Such researches as those last referred to are unquestionably of great interest, and, if pursued to a sufficient extent, may possibly lead hereafter to important practical results. Their objects differ, however, from those of the investigation, the results of which are embodied in this report, and which was undertaken with a view to ascertain, by an application of our present knowledge of the chemical and physical properties of cast iron, the relative qualities of various descriptions of pig iron submitted by numerous manufacturers.

There is no question, however, that it is in most instances very important to perform complete analyses of materials which are to be employed for the extraction of metals; for as these, at the high temperature necessary in the process of their reduction from ores, are endowed with powerful affinities for many of the frequent constituents of such ores, their properties will suffer more or less important modification by union with some of these components in the course of their reduction.

The quality of the product may therefore be, to some extent (when the treatment is under control), predicted from the results of a complete examination of the materials employed. It is, consequently, not only essential to ascertain the general composition of an ore, for the purpose of determining the nature and proportions of the auxiliary materials (fluxes) to be associated with it in the reduction process, but it is also of considerable importance to ascertain whether, and in what proportions, such constituents (as foreign metals, sulphur, and phosphorus) are contained in the ores, as are likely to enter into

* Report of Experiments on British Irons, Ores, &c., for the Manufacture of Cast Iron Ordnance.

the composition of the product, and exert an influence upon its properties.

In the chemical examination of the large series of iron samples, and materials employed in their manufacture, the system of analysis adopted has been based upon the principles embodied in the foregoing remarks.

The analyses have been performed by Mr. John Spiller, formerly chemical assistant at the Royal College of Chemistry, and subsequently at the Government School of Mines; and Mr. Arthur Reynolds, late an assistant at the College of Chemistry.

The samples of ores received from the manufacturers have been all submitted to complete analysis, excepting in the following instances:—

1. In one or two cases where the samples were found to be identical in character with some of the series of ores recently submitted to complete analysis at the Government School of Mines, under Dr. Percy, the results of which have been published in the "Memoirs of the Geological Survey of Great Britain."

The close resemblance of the samples to those above alluded to was established by a comparison with the descriptions given of the ores in the Government Report, by a careful examination of them made by Mr. Spiller, who performed a large number of the analyses alluded to in that report while at the School of Mines, and was well acquainted with all the specimens examined; and lastly, by a determination of the most important constituents of the samples received (*i.e.*, the oxide of iron and phosphoric acid), and a comparison of the results with those of the published analyses.

In these instances, as a complete analysis of the samples would have involved a very considerable unnecessary expenditure of time, it was not undertaken; but the detailed analyses of the ores, to which the samples corresponded, have been extracted from the Government Report.

2. A few of the ores received had been submitted to the roasting process. As the effect of this treatment of an ore is greatly to modify its original composition, partially expelling certain constituents, and altering the arrangement and state of combination of others, a detailed analysis would afford no direct indication of the original nature of the ore. In such instances, therefore, it was only considered important to determine the per-centages of iron, and of those constituents which might affect the quality of the metal obtained from the ore—the phosphoric acid and sulphur.

3. The ores sent by some manufacturers were identical in their nature with those from other works, and of which complete analyses have been made. In these instances the most important constituents of the samples in question have alone been determined, references having been made, when needful, to the full analyses.

The minerals employed as fluxes were all submitted to complete analysis, except in one or two instances, when their identity with samples already analysed was established by the determination of one or two constituents.

The examination of the fuel was partial, the only important object being to determine to what extent it might contain mineral matters possibly prejudicial to the quality of the metal reduced by its means. The examinations, therefore, included determinations of the amount of sulphur in the coal or coke, and the amount and character of the ash furnished by incineration. It was also considered interesting to determine the amount of coke furnished by the different samples of coal.

The analyses of the samples of iron were, for the reasons already stated, limited in most instances to the determination of the proportions of those constituents which have already been satisfactorily proved to exert some influence on the quality of the pig iron, or on the results obtained by submitting it to subsequent processes of manufacture.

The constituents in question are manganese, silicon, phosphorus, sulphur, and carbon.

With reference to the last-named substance, it may be necessary to observe, that almost all the specimens of pig iron examined which are included in this report were varieties of grey iron, and that but very few of the samples contained any appreciable amount of carbon in the combined form.

It was, therefore, of no importance or interest to determine the minute portions of carbon existing in the samples in the latter form, and this was proved by special examinations of a few of the light grey samples of the series, in which the amount of combined carbon was not found to exceed at highest 0·35 per cent.; and also by the determination of the total amount of carbon in a sample of No. 1 pig iron, the result obtained being identical with that afforded by the direct estimation of the carbon existing as graphite.

In two or three instances it was considered interesting to examine specially for certain foreign metals which had been found to exist in appreciable quantities in some of the ores from which the samples thus examined had been obtained.

Description of the Analytical Processes employed in the Chemical Examination of the Irons, Ores, Fuels, and Fluxes.

I.—Analyses of the Iron Samples.

Preparation of the Sample.—Preparatory to its examination, the metal was reduced to a suitable state of division by boring, turning, or planing. In the case of white iron it was broken to a coarse powder in a steel crushing mortar. It was considered preferable to prepare an average sample of the pig by boring across it, so that a fair proportion of the graphite, which was occasionally concentrated towards the centre or the pig, might be included in the sample. The fine borings obtained in this way were further reduced when necessary, and thoroughly mixed by trituration in a Wedgewood mortar.

Chemical Analysis.—In the analysis of pig iron the proportion of the following constituents were usually determined: maganese, carbon, silicon, sulphur, phosphorus, and, in certain cases, metals such as arsenic, lead, and copper, when their existence in appreciable quantity had been discovered in the ores from which the iron had been obtained.

For this purpose four portions were usually weighed out:—

a. 100 grains for sulphur, carbon existing as graphite, silicon, and manganese.

b. 50 grains for phosphorus.

c. 50 to 100 grains for determining the existence and amount of combined carbon.

d. 500 grains for metals existing in the iron in minute proportions.

Sulphur.—100 grains of the iron borings were slowly dissolved in concentrated hydrochloric acid, the evolved gas being passed through a solution of acetate of lead, slightly acidified with acetic acid, the sulphuretted hydrogen, disengaged together with hydrogen, precipitated the sulphide of lead, which was collected on a filter, washed, burnt, and subsequently, in the customary manner, converted into sulphate of lead, from the weight of which the per-centage of sulphur was calculated.

The contents of the flask, after the metal had been fully acted upon, were transferred to a porcelain basin and evaporated to dryness, the mass digested with concentrated hydrochloric acid, and water afterwards added. The insoluble residue, consisting of silicic acid and graphite, was collected on a filter, the filtrate being reserved for the estimation of manganese.

Carbon as Graphite.—The mixed silicic acid and graphite were separated by the action of a warm solution of pure potassa, when the silicic acid was dissolved, the graphite which remained insoluble was again collected, washed with dilute hydrochloric acid and water, and dried. It was afterwards carefully removed from the paper by scraping with a knife blade, and transferred to a platinum crucible, in which, after exposure for some time to about 300 deg. F., it was weighed. Upon subsequently burning the graphite in a muffle, it usually left a very small quantity of reddish ash, which was deducted from the former weight.

Silicon.—The amount of silicic acid dissolved by the potassa was recovered in the usual manner, by evaporation with hydrochloric acid; the residue was digested with water, collected, washed, dried, and weighed. The amount of the silicon in the iron was calculated from the silicic acid obtained.

Manganese.—The hydrochloric acid solution, separated from the silicic acid and graphite, was divided into two equal portions, one of which, representing 50 grains of iron, was always sufficient for the estimation of the manganese. The iron in the liquid having been per-oxidised by boiling the hydrochloric acid solution, and adding occasionally a little chlorate of potassa, the acid was to a great extent neutralised by addition of carbonate of ammonia. Sufficient acetate of ammonia was afterwards added for the conversion of the chloride of iron into acetate, and the liquid was boiled, when the iron was completely separated as insoluble basic acetate. The filtrate containing the manganese was rendered alkaline with ammonia, and, after the addition of a few drops of bromine, set aside for about eighteen hours. The hydrated binoxide of manganese which had separated from the liquid, was afterwards collected, washed, dried, and ignited at a high temperature, when it was weighed as manganoso-manganic oxide (Mn_3O_4), which furnished, by calculation, the quantity of manganese.

ON THE CONFORMATION OF THE ALPS.

By Professor Tyndall, F.R.S. *

During the last seven summers I have had opportunities of viewing the Alps from many commanding points of view, and while in such positions have often speculated on the agencies which have given this portion of the earth's surface its remarkable conformation. How have the hills risen, or how have the valleys sunk? I think the mere inspection of the mountains from a sufficient elevation must suggest insuperable difficulties to the assumption that the present mountains have arisen through the action of forces localised beneath their bases, or that the valleys, as they now exist, can have sunk through want of local support underneath. Probably nobody entertains such a notion. Upheaval may have occurred, and sinking may have occurred; but it is next to inconceivable that either action should have been so parcelled out as to produce the present conformation of the Alps. A *general elevation* of the land must be assumed, producing a kind of lopsidedness as regards the figure of the earth; and the question then occurs, how has the land, thus elevated, been carved into its present form?

In the uplifting of the land, cracks and fissures would probably be produced, and the valleys migh be regarded as the traces of these cracks and fissures—widened and deepened, it may be, by subsequent denundation. But the direction of the valleys is not that in which cracks would take place. The valleys generally follow the line of steepest fall, and this would be the line of greatest tention on the lifting of the mass; consequently, the mechanical conditions of the problem would lead us to infer cracks at right angles to the present valleys instead of along them. Take, for example, the ridge from Monta Rosa over the Lyskamm and Breithorn to the Matterhosn; the upheaval of that ridge could not possibly produce rents in the position now occupied by the Val Tournanche, the Val d'Ayas, and the Val du Lys. The line of strain would be parallel to these valleys, and hence the line of fracture, if fracture at all occurred, across them.

A sufficient consideration of the subject must, I think, result in the conclusion already expressed, that a general elevation of the land formerly existed, and must limit us to the question, "By what agency has this land been scarred so as to exhibit the valleys by which it is now intersected?" These valleys are the tracks of rivers, and have been manifestly formed with reference to the discharge of the aqueous precipitations which occurred on the heights. An eminent

* Communicated by the Author to the *Philosophical Magazine.*

Swiss geologist, with whom I had an opportunity of conversing a week or two ago, called the Alpine valleys "Auswaschungsthäler," valleys cut out by the action of water. For some years an opposite conclusion has been gradually forcing itself upon me; and this year I completed a chain of evidence which leaves little doubt upon my mind that a mightier excavator than mere water has been at work among the Alps, and that the country owes its present conformation mainly to the action of its ancient glaciers.

It requires some time to realise the stupendous scale on which the ancient ice has operated; and were its traces less indubitable, the judgment would halt before accepting a conclusion involving operations so vast as almost to appear fabulous. This year I walked for the fifth time up the valley of Hasli, observing the action of the ancient glacier upon its boundaries. A million winters may have acted upon these scarred and fluted rocks, and still the scars and the flutings are as distinct as if they had been executed last year. We trace them down to the banks of the Aar, a river which has been rushing for these ages through the valley; and the smallness of its operations must impress us with the *comparative* feebleness of denudation by water. A mighty glacier occupied the valley of the Rhone. I traced it all along the valley to Martigny, a distance of more than sixty miles from the end of the present Rhone glacier. Here, reinforced from Mont Blanc, it ploughed its way towards the Lake of Geneva. Near a station called D'Evionnaz, the *roches moutonnees* rise above each other in heaps, and here, as in Haslithal, the polishing comes down close to the level of the present Rhone,—thus suggesting how *comparatively* small has been the action of the river from the disappearance of the glacier to the present day.

The same thought is continually forced upon the traveller on the south side of the Alps, where the traces of ancient glacier action are, if anything, more astonishing than on the north. Two years ago I had an opportunity of inspecting the Val Tournanche from Breuil to Chatillon. This year I crossed the Cimes Blanches from Breuil, wandered over the ancient névés of the place, penetrated the higher ramifications of the Val d'Ayas, and everywhere found the sculpture of the ancient ice. Crossing the Col Betta Furka, and looking down the Val du Lys, the work of the glacier which once proceeded from the slopes of the Lyskamm was immediately manifest. I traced the action through this noble valley, as far as Gressonay St. Jean; everywhere on the valleys' flanks the same truth was proclaimed. What air and water have accomplished since the disappearance of the glaciers are mere scratches of the tooth of time, in comparison with the mighty furrows which had been previously ploughed out.

From Gressonay I crossed the Col de Val d'Obbia to Alagna, and everywhere I trod upon ground deserted by the ice. Like its neighbour of the Lys, the Val Sesia also formed the bed of a mighty glacier. From Alagna I crossed the Turloz; the traces of the ice are here magnificent, and on the flank of the Val Anzasca, opposite the place where the glacier from Mont Turloz joined that from Macugnaga, the rocks are wonderfully worn; all up the Macugnaga valley to the base of Monte Rosa the same grand evidences appear, forcing upon the mind the existence of a state of things so extraordinary that, were the proofs less strong, the imagination would shrink from any attempt to realise it. I have repeatedly explored both the Saasthal and Nicolaithal; both of them are glacier channels; an expanse of particularly finely-rounded rocks may be seen on the side of the Saasthal at the place where the road turns up to the valley of the Fee.

Having finished the exploration of this part of the country, I felt a strong desire to visit the Jura, and to observe for myself the boulders scattered over its slopes. I accordingly went to Neuchatel, visited the celebrated Pierre-à-Bot, and examined the general character of the moraine-like matter which is strewn over the slopes. Granite boulders were abundant, being in many cases quarried for building use. The Jura, as is well known, yields no granite; it is composed of limestone. Whence, then, did these blocks come? Limestone is a partially soluble rock, and hence, when long exposed to the air, although it may preserve the general form imparted to it by the grinding action of a glacier, it does not retain the finer striæ which enable one to determine the direction of motion. I therefore sought for slabs of limestone from which the protecting soil had been recently removed, and was fortunate enough to find some very fine ones, in which the glacier scratches were marked with perfect distinctness. I determined the direction of these scratches at three different places, and found them coincident: they all pointed to Mont Blanc,* which was the place where the ancient glaciers had received their load, carrying with them across the Canton-de-Vaud, occupying the bed of what is now the Lake of Neuchatel, and depositing them on the slopes of the Jura. The railroad between Neuchatel and Brienne has disclosed several well-scarred rocks; the evidence of glacier-action is here just as conclusive as in the other parts of the Alps; and the fact of ice moving thus across the country from Mont Blanc to the Jura, fortifies the conception previously formed of the magnitude of the phenomenon.

It is, then, perfectly certain that all this mountain region was held by ice, enormous as to mass, and in incessant motion. That such an agent was competent to plough out the Alpine valleys cannot, I think, be doubted, while the fact that during the ages which must have elapsed since its disappearance the ordinary denuding action of the atmosphere has been unable, in most cases, to obliterate even the superficial traces of the glaciers, suggests the incompetence of that action to produce the same effect. That the glaciers have been the real excavators seems to me far more probable than the supposition that they merely filled valleys which had been previously formed by water denudation. Indeed, the choice lies between these two suppositions:—Shall we assume that the glaciers filled valleys which were previously formed by what would undoubtedly be a weaker agent? or, shall we conclude that they have been the excavators which have furrowed the uplifted land with the valleys which now intersect it? I do not hesitate to accept the latter view, and this view will carry us still further. According to it the glacier is essentially self-destructive. The more deeply it ploughs the surface of the earth the more must it retreat. Let the present Alpine valleys be filled to the level of the adjacent ridges, and vast glaciers would again start into existence; but every one of these valleys is a kind of furnace which sends draughts of hot air up to the heights, and thus effectually prevents the formation of ice. While standing on the summit of the Grauhaupt a week or two ago, I was perfectly astonished at the force with which these gusts of heated air rose vertically from the Val du Lys. Marked by the precipitated vapours which chanced to be afloat at the time, the vertical gusts were often as violent as the draught from a factory chimney. Thus, given the uplifted land, and we have a glacial epoch; let the ice work down the earth, every foot it sinks necessitates its own diminution; the glaciers shrink as the valleys deepen; and, finally, we have a state of things in which the ice has dwindled to limits which barely serve as a key to the stupendous operations of a bygone geologic age. To account for a glacial epoch, then, we need not resort to the hard hypothesis of a change in the amount of solar emission, or of a change in the temperature of space traversed by our system. Elevations of the land, which would naturally accompany the gradual cooling of the earth, are quite competent to account for such an epoch; and the ice itself, in the absence of any other agency, would be competent to destroy the conditions which gave it birth.

Royal Institution, August 18, 1862.

* That is, in the direction which a local guide pointed out as that of Mont Blanc. The mountain itself was not seen.

AMERICAN IMPROVEMENTS IN TANNING.

THE following is from a contributor to the *Shoe and Leather Reporter*:—

"Among all the improvements of the age the American tanners have kept up with the times. There are many names to be remembered in this connection. Toby, of Hudson, made the first bark mill, and it has been little improved since his time. To Perego and his partner we owe the improved apparatus now used to draw the liquor from the bottom of the vats. The original heater for leaching bark was first used by a Quaker tanner, near Poughkeepsie, and it was afterwards improved and patented by another. The invention of the roller was always claimed by Jeremiah Guyle, also by Deacon Munson, though patented by Col. Edwards."

At the commencement of the present century, few establishments had adopted either steam or water power, but now in this State alone we have 125 tanneries supplied with steam engines, and 418 which use water power.

In the year 1826, by a more judicious use and a more scientific gradation of the tanning liquors, and by omitting to skive, we began to make a greater proportionate weight of leather; a change productive of many advantages, not the least of which was that it left money in the bank. In my early days, 16, 20, and 30 per cent. was called a good gain of weight. Now, 50 to 80 per cent. is none too much.

I well remember an old tanner who, passing his journeyman as he was hard at work skiving down the butts and necks of the hides on the beam, patted him on the shoulder, and said:—"Young man, I had rather pay you to leave that on." Neither tanner nor journeyman have lost anything by that lesson."

THE DECIMAL SYSTEM OF WEIGHTS AND MEASURES.

THE report of the select committee appointed to consider the practicability of adopting a simple and uniform system of weights and measures is published. The following recommendations are laid before the house, together with a great mass of evidence and tabular appendices:—

1. That the use of the metric system be rendered legal. No compulsory measures should be resorted to until they are sanctioned by the general conviction of the public.

2. That a Department of Weights and Measures be established in connection with the Board of Trade. It would thus become subordinate to the government and responsible to parliament. To it should be entrusted the conservation and verification of the standards, the superintendence of inspectors, and the general duties incident to such a department. It should also take such measures as may from time to time promote the use and extend the knowledge of the metric system in the departments of government and among the people.

3. The Government should sanction the use of the metric system (together with our present one) in the levying of the customs' duties; thus familiarising it among our merchants and manufacturers, and giving facilities to foreign traders in their dealings with this country. Its use, combined with that of our own system in government contracts, has also been suggested.

4. The metric system should form one of the subjects of examination in the competitive examinations of the civil service.

5. The gramme should be used as a weight for foreign letters and books at the Post-office.

6. The Committee of Council on Education should require the metric system to be taught (as might easily be done by means of tables and diagrams) in all schools receiving grants of public money.

7. In the public statistics of the country quantities should be expressed in terms of the metric system in juxta-position with those of our own, as suggested by the International Statistical Congress.

8. In private bills before parliament the use of the metric system should be allowed.

9. The only weights and measures in use

should be the metric and imperial, until the metric has been generally adopted.

10. The proviso in the 5th and 6th Wm. IV., chap. 63, clause 6, allowing the use of "local and customary measures" in cases were the vessel employed "is not represented as containing any amount of imperial measure or of any fixed local or customary measure heretofore in use," should be repealed, as giving facilities to evade the statute.

11. The department which it is proposed to appoint should make an annual report to parment.

REVOLVING FIRE-ARMS.

MR. J. DEANE, junior, of King William Street, gun manufacturer, has just obtained a patent for "Improvements in revolving fire-arms."

The invention relates to pistols, rifles, and other small fire-arms in which there is a revolving breech chamber, and consists in so constructing the breech as to admit of such chamber being loaded at the rear, as hereafter explained.

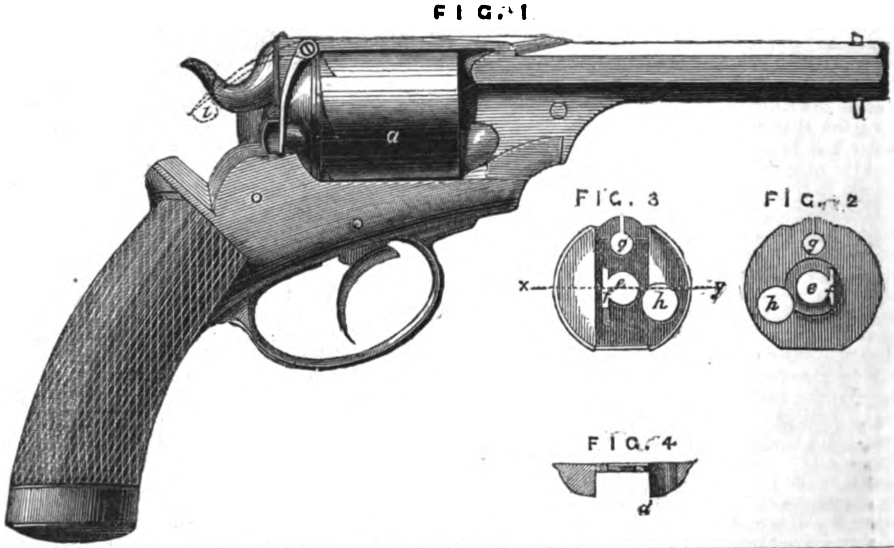
The invention consists in the employment of an independant breech-piece or shield, together with a revolving chamber, in which the compartments for receiving the charge are bored or formed entirely through the length of such chamber. Through this breech-piece and on one side an aperture is made, through which a cartridge is inserted into one of the compartments of the revolving chamber; the chamber is turned so as to present another compartment, and so on until the whole of the compartments have been charged. A plate connected to one end of an arm, free to move on a pin connected to some fixed part of the arm, is then brought down to close the aperture in the breech-piece, and the pistol or gun is fired by the hammer striking through an aperture made for the reception of the nose thereof in the shield on a cap or detonating powder at the rear of the cartridge.

Fig. 1 of the above engravings is a side elevation of a revolving pistol, showing the invention applied thereto. Fig. 2 is a face view, fig. 3 a back view, and fig. 4 is a section, through the line *xy* of fig. 3, of the independent breech-piece. *a* is the chamber, with compartments for holding the charge bored throughout the length of the chamber, free to revolve on a spindle in the usual manner; *b* is the independent breech-piece passed over the spindle; it is planed out at the back to form a recess, into which the lump *c* enters the sides; *d d* overlap the sides of the lump; *e* is the aperture through which the spindle passes; *f* is the slot through which the lever for causing the rotation of the chamber works; *g* is the opening to allow of the hammer striking the cartridge, and *h* is the aperture through which the cartridges are inserted into the compartments in the revolving chamber. The entrance to the aperture in the shield is rounded off, to facilitate the insertion of the cartridges; *i* is a plate on the end of an arm *k*, free to turn on the pin *l*. This plate is turned to cover the aperture *h* after the chamber has been charged. It is turned up, as shown by the dotted lines, to allow of the insertion of the cartridges into the compartments in the chamber.

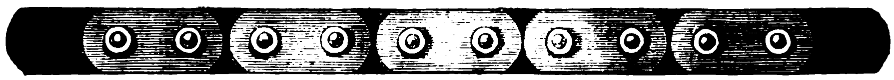
The chamber and the breech-piece or shield are capable of being removed, when a revolving chamber fitted with nipples may be substituted. Should the prepared cartridges be exhausted, it may be desirable to unship the breech-loading chamber and breech hereinbefore described, and use the arm as an ordinary revolving chamber, pistol, or gun. In like manner, this invention may be applied to breech-loading guns and fire-arms where a revolving chamber of the ordinary construction is now used.

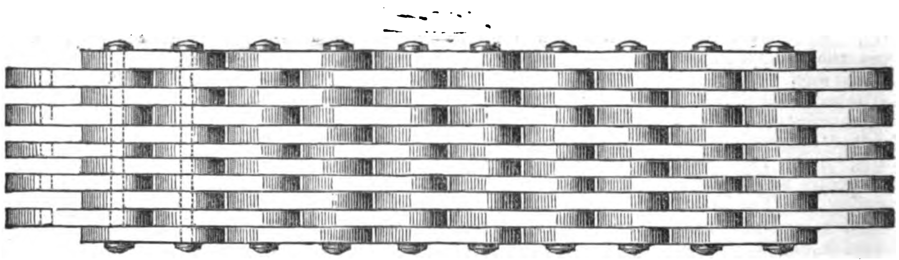
The largest artificial reservoir of water in the world was completed last month to supply the city of New York with water. It is situated in the central park in that city. The purchase of the land cost £100,000, and the formation of the reservoir cost £300,000; 96 acres are covered with water. The depth of the reservoir is 50 feet, and it would hold 1,100,000,000 gallons of water.

REVOLVING FIRE-ARMS.



AN IMPROVED MILL BAND.



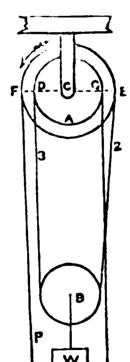


PAYNE'S FLAX MACHINE.

THIS machine, patented by Mr. B. Payne, of Chard, Somerset, consists of a box or case in which the flax or other fibrous material to be operated upon is to be placed. The bottom and sides of the box are provided or lined with corrugated, roughened, indented, or toothed metal friction plates, as shown in the above engravings, against which the fibrous material is rubbed by the action of the beaters, and is thereby submitted to considerable friction. Part of the bottom of the case is formed of a steam chest, which is supplied with steam from a boiler, and is covered with a plate of copper and another of lead, with a layer of felt between them. By this combination of plates of copper and lead, with a sheet of felt between them, a bed is obtained possessing a certain amount of elasticity, and one that is also capable of holding and tempering the heat given off from the steam chest. A perforated steam pipe is also let into a suitable recess at the bottom of the case, and steam is injected therefrom into or on to the mass of fibres in the case, while the material is being submitted to the friction of the beaters. The back part of the case is made moveable on a hinge, and is adjustable so that it may be moved into a forward or backward position on such joint by means of the screw adjustment. The screw passes through a nut in a crosshead, fixed in jointed arms, attached to the moveable part of the casing, and this moveable part is secured in any desired position by means of a click or pall, which takes into the ratchet wheel on the end of the screw. Hollow beaters provided with toothed, serrated, indented, or roughened surfaces, both at their faces, backs, and sides, are secured on the ends of arms, which are mounted on pivots at the upper end of the vertical standards. A tappet wheel provided with arms, is mounted below the projecting ends of the beater arms, and as the tappet wheel rotates, it will lift up the beaters, and allow them to fall upon the raw flax or other fibrous material that is placed in the apparatus. Openings are made in the sides of the case to allow the dust from the fibres to pass off. This beating action creates a considerable amount of friction, and, in addition to this, steam is injected from the perforated pipe. By the combined operation of the beaters with the steam and heat, the woody parts of the plant are detached from the useful fibres, and the latter are rendered soft and brought into a proper state for the subsequent operations of heckling, combing, and spinning.

DIFFERENTIAL PULLEY BLOCKS.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."



SIR,—For your own satisfaction as to the truth of my previous note, I beg to enclose you a copy of the passage in Carpenter's "Mechanical Philosophy," which I referred to.

"An extremely simple and ingenious application to the pulley of the principle which has been mentioned under the head of the Chinese wheel and axle, has been devised by Mr. Moore, of Bristol. Its beauty consists in permitting an increase of power to any extent by the employment of only two pulleys. Its construction will be readily understood from the accompanying diagram. A is a fixed pulley with two grooves of which one is a little larger than the other. An endless cord passes over the larger groove from F to E, then beneath a moveable pulley, B; after which it returns over the smaller groove from D to G, and hangs down, so as to become continuous with the first line. Now, if a power be applied at P, so as to draw down the line 1, the line 2 will be raised to the same amount, and the circumference of the pulley A will move through the same space. Supposing that the line 3 were fixed at its extremity, the pulley B would be raised by half the amount to which the line

2 is shortened. But the revolution of the pulley A, whilst it draws up the line 2 over one groove, lets down the line 3 from the other. If the 2 grooves were of the same size, therefore, the pulley B would not be raised, since the line 3 would descend as much as 2 ascends. But, in consequence of the different size of the grooves, the line 3 does not descend as fast as 2 ascends; and the rise of the pulley B will, therefore, be equal to half the difference in the amount. But if the larger groove have a circumference of 18 inches, and the smaller of 15 inches, the line 2 will be drawn up by one revolution of the pulley A through 18 inches, whilst the line 3 will descend through 15. The moveable pulley B, with the weight attached to it, will consequently be made to ascend through 1½ inch, whilst P descends 18, and the power gained will be 12.

"The reason of this gain of power is at once seen, by considering that the action of the weight upon the string 3 tends to turn round the pulley in the direction of the arrow nearly as much as the action of the string 2 tends to turn it in a contrary direction; and that a small force applied to P will, therefore, overcome the difference. If, as in the present instance, the distance from C to D be 15, and from C to E 18, a weight bearing on the string 3 would cause the pulley A to move in the direction of the arrow with a power of 15, whilst the same pressure on the line 2 would make it turn in the contrary direction with a power of 18. The difference between the two strains, therefore, will be the real amount of resistance to be overcome by a power applied to the circumference of the larger groove of the pulley A; and this will be one-sixth of the strain upon either of the strings. But this strain is only half the total weight suspended to B, and the power of the combination will hence be 12. It may be increased to any amount, by diminishing the difference between the two grooves. Thus, if the larger one have a diameter of 100 parts, and the smaller one of 99, the resistance to the motion of the upper pulley will only be 100th part of the weight bearing on each string, or 200th of the whole weight suspended to B. As the cord has no fixed extremity, and as the action of the pulleys would be altogether destroyed if it had the power of *sliding* over them, it is necessary to take some means of preventing this. The simplest is the employment of a chain, instead of a cord, the links of which are laid hold of by pins projecting from the surface of the wheels. The author may express his surprise that this ingenious invention has not come into more general use, since it enables any amount of power to be obtained without any corresponding enlargement of the apparatus, or increase of friction."

I now find that Mr. Weston has patented this invention of twenty years since—another instance of wasted money from imperfect investigation.

I am, Sir,
Yours obediently,
ARTIZAN.

London, 15th Sept., 1862.

AN IMPROVED MILL BAND.

The above engraving illustrates a mill band of a novel construction, which consists of a number of small pieces or links of leather, pinned together in such a manner that a flexible band is secured. The inventor, C. M. Roullier, of Paris, proposes to use waste pieces of leather for the purpose, and to gain sufficient strength the outer links may be of metal. The straps can be made of any width to suit any class of machinery. We feel confident our engineers, generally, will see the advantage of the above invention, which will tend to obviate the great loss of time occasioned by the breaking of straps.

DOUBLE GUNBOATS.—SUBMARINE CABLES.

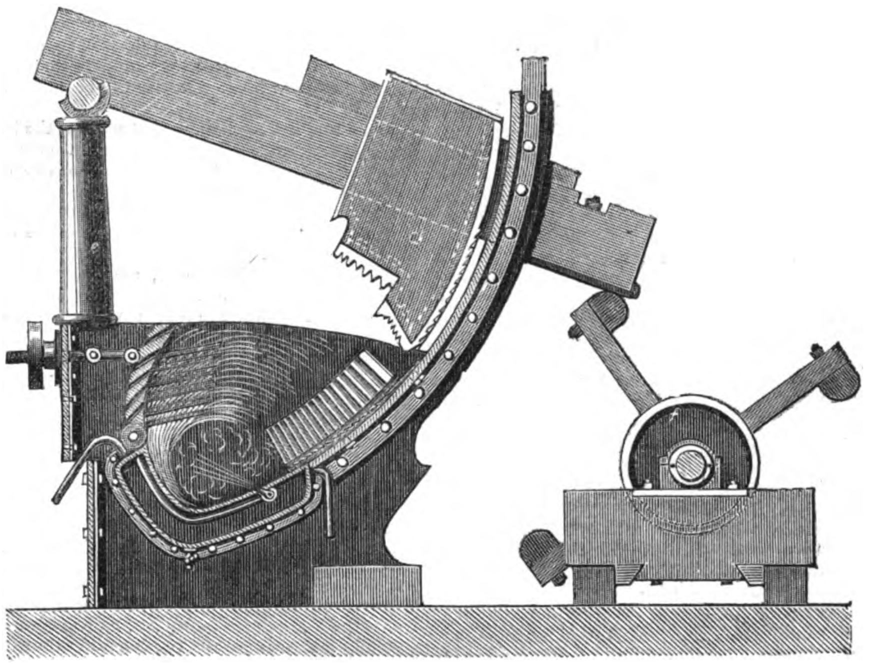
TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

Dear Sir,—There are two subjects to which reference is made in your last number, and in which I am particularly interested. I refer first to the Atlantic telegraph cable, and secondly to the proposition about double gunboats made to the admiralty.

I hope you will allow me to make a few observations on each of these.

With respect to the latter, I am much obliged by your recalling to the recollection of your readers (no inconsiderable portion of the scientific public) the fact that, some time since, I had written a letter to the Mechanics' Magazine on the subject, proposing the utilization in this way of our fleet of old gunboats; and I have to remark that the proposition, which is now mentioned as being listened to at the admiralty, embraces some fallacies, from which I had thought it necessary carefully to guard my project.

PAYNE'S FLAX MACHINE.



One of these fallacies is the heaving of two bows. Were this done, I do not hesitate to say that the speed would be more likely to be four knots than twenty-four. Not being so sanguine, and having possibly a little more experience of what gunboats *will do*, I should be very well satisfied to get the half of 24 knots, and I should expect to obtain that result—not by complicating the machinery with *anybody's* paddles, but by using the two screws as they are. The gunboats would be as useless as they are now for purposes of coast defence against rams or molten iron, shells, if they did not carry armour; and I do not believe that this could be done efficiently if there were paddles, horizontal or vertical, under water or above it, applied at the sides. The ram to which they certainly ought to possess can be no where so safely placed as between the two bows, while being there it would prevent the water getting "wedged" at that part, which would certainly cause, if it did occur, quite as much retardation as I have just stated.

Of course I do not believe that these are the best vessels which could be constructed for the purpose, but it would be a cheap way of trying the experiment of double screws, rudders, &c.; and I believe that two or three of such vessels would be very awkward customers for any of our present ironsides, which are no more safe against rams than the oldest wooden ship.

It should be remembered that longitudinal compartments as well as transverse ones are the only real defence (if defence be possible) of an iron ship against rocks and rams. It is all very well to say that merchant ships have been saved with one compartment, or even two, full of water; but what, we may ask, would be the consequence if in that or those compartments had been situated in a man-of-war, the engines with their fires, the magazine with its supply of powder, the shell-room, or even the shot-locker; longitudinal partitions, therefore, must be built answering to what used to be called the wings of the orlop deck, and which were always kept clear for stopping shot holes, when taking place, as every sailor knows they did, at or below the water line. These must be placed fore and aft the ship (they might contribute largely to the strength of the structure) at least 10 feet in from the side, or as far as the blow of a ram might be likely to bulge in or pierce it. These compartments, again, should be divided into cells by transverse *fixed* partitions so as to confine the leakage as much as possible.

As none of the modern armour plated ships carry their armour, even with all their coals on board—much more than five or six feet below the water line; and as they do not seem, to say the least of it—*indisposed to roll*—it follows that on active service, they would very frequently be pierced below the armour by shots and shells of certain descriptions, while that of course is the part which will always be attacked by a ram.

There is but one form of vessel which could attain a high speed, carrying efficient armour throughout above, and unpierceable by rams; that is, an extremely wide and shallow one, great beam and light draught. But this is not easily compatible with screw propulsion, though there are other methods which might be adopted. My present aim is to show how defects may be remedied in existing structures, not to make proposals of the best possible new one. I certainly cannot regard any of those recently built, or now building as being great strides towards the "*Fleet of the future*," seeing that there is not one of them that would dare to closely ngage an efficient ram, even if only a tenth of her size.

The Submarine Telegraph.

But I turn to the other subject, one which I confess has many more attractions for me than any scheme for the improvement of means of destruction. The submarine telegraph, one of the great bonds of peace to the whole human race; and here, too, I wish to overthrow some fallacies.

If any of your readers will take the trouble to look at Captain Dayman's soundings they will see that there is a distance of about ten miles between each of them wherever this could be done. I have not the book before me at present, but I can affirm that in the presence, and with the assistance of Captain Becher, examined the latitudes and longitudes of each of the soundings near what has been falsely called the Irish precipice. On reducing the miles distance between those soundings into feet, as also the depth, we found that the rise was about 1 in 16—a little less steep than Holborn-hill.

I am credibly informed that even this is more than can be proved to exist since the "Porcupine" has sounded over the ground again. But who in their senses, if it did exist, would think of such a declivity as a "precipice," or try to show that this was the cause of the damage to the late Atlantic cable, unless to cover *peculiar proclivities.*

"Bad workmen always find fault with their tools," and the "moral causes," which never

should have existed, as well as the physical causes, which never did exist, have been far too heavily blamed for shortcomings of the gentlemen who have been learning "*how they cannot do it*." But the special value of the "Porcupine's" voyage of discovery seems to have been divided between the finding of a "gap" which nobody wanted, and the survey of a cod-bank, which can surely have very little to do with a cable. On which of these subjects is the Admiralty about to make a communication to the Atlantic Telegraph Company, with a view, of course, to the raising of fresh capital, and what will be the security against further loss to shareholders?

Mr. Cyrus Field, who is certainly a most energetic director, can, I fear, as little galvanize into life a defunct company as a destroyed cable; and one would imagine that the Federal government, who may or may not be now at Washington, have nearly enough to do with what money they have (leaving paper out of the question) without helping us to lay a cable.

If the problem of an Atlantic cable is to be rightly solved, it must be done by a company who have been fortunate enough to profit by the experience, without having incurred the losses incidental to a want of success; and though this may seem hard measure, it is not really so, for companies are not in the same position in this respect as individuals.

A company may always be re-constituted, and those who lost by the first scheme can always, if they choose, try to recover their loss by a wise use of the experience they have bought. But no person having a choice would be likely to attach himself to an association, which rejecting experience, fighting against facts and advocating unumbered fallacies, should offer only the old encumbrances which have ruined, and the old method which have failed, backed by a bet, that this time it *will* be done, that bet being very much on the principle of heads I win tails you lose.

I have lately also seen a notice of the lying of a cable across the North Sea with the aid of fishing boats stationed at intervals. I hope the said fishing boats will not be brought forward as a good idea for the Atlantic cable; but there is no telling what folly may not be proposed, I confess I think it a very clumsy expedient even where it *was* adopted, and it certainly does not seem to have had the effect of getting rid of kinks. They speak of these occurring and the "*brave*" way in which they were pulled out. When will cable manufacturers and *layers* be convinced that the wise thing to do, is to avoid making kinks, not to claim credit for pulling them out? and that this can only be done by winding on a reel, not coiling in a hold?

Half or two-thirds the damage which has been ascribed to other causes arises from this source, and it cannot be too strongly impressed on those who study the subject, that a kink may be, and often is, fatal to the insulation of a copper conductor, whether pulled out or not, and certainly never does it any good.

Another thing is, that no ship ever anchors in water so deep as 60 fathoms if she can help it, and can very seldom recover her anchor if she does, so that damage from that cause ought to be much more limited than has yet been the case.

In shoal water there is, no doubt, considerable difficulty from ships' anchors, but this might be met by heavy rewards for conviction of offenders, almost as well as by heavy cables which involve great difficulty in lifting when damage occurs, which it is sure to do sooner or later. I should prefer, even here, a moderately light cable, with the strength in the centre, for the greater portion, to be laid slack, and a considerable reward for everyone who, having caught it, threw it off uninjured, or for conviction of any one who wilfully damaged it. There are certain portions of every shore off which vessels never anchor. Let these be chosen for the telegraph route rather than the straightest line between two points, and then the submarine companies may look for a rise in the dividends, and their cables will not be such bugbears in the accounts. This is the reason why some submarine lines *have not cost a shilling for repairs*, while others go far into thousands of pounds for the same purpose. Telegraph companies would often do well to remember that "the longest way round is sometimes the shortest way home," under the ocean as well as on it.

I was told not long since that some of the leading telegraphic engineers express themselves "sick of submarines." I am delighted to hear it, for now the nautical engineer may have a chance of being listened to, and of showing that all science is not confined to those who know nothing of the sea.

That the difficulties can be, and will be, overcome, that the cable will eventually be laid, I am as confident as that the earth moves. That I may be one of the humble instruments in doing so I fervently hope, and try to qualify myself for—not by ignoring, but by consulting facts—not by pride and prejudice—but by patience, perseverance, and as much sweet oil as I can afford—for fallacies.

J. N. SELWYN, Capt., R.N.

Chequers Court,
Tring, Herts.

AN AMERICAN IRON-CLAD STEAMER.

The United States iron-clad gunboat "Passaic," which has been known as the Ercisson Battery, No. 2 (the "Monitor" being No. 1), has been successfully launched at the Continental ironworks, Greenpoint. The "Passaic" is an iron-clad steam gunboat of 1,000 tons burden. She is 200 ft. long, 45 ft. wide, 12 ft. deep, draws 7 ft. of water now, and will draw 9½ ft. when laden. These figures would give a good idea of a wooden vessel; they can convey no impression of this one. She looks like a huge coal barge with a sloping house on deck. She is as thick as two ordinary vessels. The width of iron which is laid on a hull of extraordinary strength is 5 in. The turret is covered by wedges twice as heavy, being no less than 11 in. thick. The mail covers the entire craft, and goes beyond the bow, where it becomes a ram. It also extends 3½ ft., or half the entire draught of the vessel, below the water-line. In action, then, a ball cannot strike an exposed part, because there is no part exposed. Even the prow, or ram, might be broken clear off without serious damage to the vessel. Under each deck-beam of the upper part of the vessel, from turret bulkhead, there are three rows of stanchions of 2¾ bar iron, fastened by 1-in. bolts. Aft the turret bulkhead there will be only one central row of stanchions. Rope stanchions are placed around the vessel at intervals of 10 ft., to be made of wrought iron, with an eye at the top for receiving the rope rail. A series of powerful strong belts are also introduced all around the vessel. The vessel is provided with six water-tight compartments, connected with each other, with suitable doorways. They are formed of 1½-in. plate, butt-jointed and riveted flush. The turret is 21 ft. internal diameter. The plates, which are 11 in. thick, are applied in 20 sections, and joined vertically in such a manner that there is only one joint at any one place. The turret plates rest on a flat ring, made of composition metal 1½ in. thick and 12 in. wide, provided with a vertical flange on the inside 2½ in. high and 1½ in. thick. The top of the turret is formed of wrought iron plates, 1½ in. thick, resting on forged beams and railway bars, placed 3 in. apart inside the turret. Certain portions of these plates are perforated with holes 1 in. diameter. In the centre of this plating a circular aperture is made, 6 ft. in diameter, over which the pilot house, of equal diameter, is to be placed. The armament will of course be in the turret, which is intended for two 15-in. Dahlgren guns. The machinery consists of two engines, which are on board. They were built at the Delamater Ironworks, and have cylinders 40 in. in diameter and 22 in. stroke. The blower engines and blowers are of greater size than those of the "Monitor;" and, instead of being placed in the engine-room, are applied under the turret roof, forcing air into the boiler room and other parts of the vessel. Two boilers, of Martin's plan, are attached, of 10 ft. face, 9 ft. 3 in. high, and 12 ft. 6 in. long, with three furnaces in each. These boilers rest on 16-in. floor plate, to be felted and leaded, and furnished with all approved appurtenances. The propeller is made of cast iron, 12 ft. in diameter, with 16 ft. pitch. The "Passaic" cost 400,000 dols., which is the price to be paid for all her sister ships.

THE TRUE PRINCIPLES OF AIR NAVIGATION EXPLAINED.

TO THE EDITOR OF "THE MECHANICS' MAGAZINE."

SIR,—I feel I ought not to trespass further upon your valuable space in discussing this subject; but, as Mr. Cheverton regrets that I have not improved by his previously edifying epistles, perhaps you will permit me to enquire, how is it that he condemns the competency of his favourite authority, to whom he has pointed as worthy of my consideration? He states: "I refer him to Hutton's table of experiments, from which he may ascertain that the air will oppose to such a wing surface a resistance of about one-tenth of an ounce!" and afterwards informs me that "at any rate, be the number of strokes what they will, and however we may stumble in calculation, a resistance of the air proportional to the square of the velocity, or a little beyond it, [how liberal!] and a series of absolute resistances determined by experiments [was Hutton's table the result of absolute experiments, or the conclusion of his 'theoretical phantasy?'] and which, perhaps, for sundry reasons, are somewhat greater in fact [how reliable!] than are given in Hutton's tables."

I certainly was unprepared to apply the strict law of the squares, which altereth not, in the liberal manner permitted by Mr. Cheverton; but in his way it certainly seems capable of meeting the requirements of the case; for, after squaring the velocity, if that fails, "the amount of resistance should be doubled" for concave surfaces; and another authority informs us that it should be trebled for convex surfaces; and, should this still prove insufficient, we may reduce the velocity as 1·414 to 1. Then, if this still fails to satisfy the requirements, we are permitted to "increase the velocity of the down strokes in the same ratio (of course without the bird's consent), which will reduce the number of strokes to seventeen, and this number may be again further reduced (perhaps half), for the other reasons mentioned," in Mr. Cheverton's letter or elsewhere, when at last "we should arrive at a number of strokes per second not at all extraordinary!" So I think: for it is not at all wonderful that, after all this squaring and doubling, and trebling and reducing, and increasing and reducing again and again, as the case may require or demand, that at last it should give results somewhat similar to those actually observable in nature, viz., that a wing surface which at the outset would only obtain a resistance equal to about 0·1 oz. will, after all this modification, prove capable of raising a bird weighing 1¼ lbs., or obtain a resistance 280 times greater than at first, which is a very satisfactory conclusion!

But I had thought that we might, like flying animals, take a shorter cut to attain this result, by demonstrating that the weight of the body on the surface of the propellers is proportional to the weight of the air upon the same surface, and that their respective velocities, therefore, must also be proportional; and which, I hope, may sooner or later meet Mr. Cheverton's approbation.

Mr. Cheverton also asserts it "to be a serious error to bring forward the elasticity of air as affording resistance to compression on which propelling efforts in flying are to act;" and requests me to "check suddenly the motion of a pasteboard surface 1 foot square," saying, "I shall not perceive the slightest elastic rebound from the compression of the air." What a powerful proof of its non-existence! Suppose, however, the pasteboard surface to be carefully cemented to the top edges of a cubical vessel of the same area, and then taken to a considerable height in the atmosphere, will the surface then experience even "the slightest elastic rebound from the compression of the air?" Of course not—because the vessel was simply filled in the open air; that is, if all the sides be sufficiently strong, and the pasteboard surface sufficiently weighted, to overpower such elastic force, due to the pressure of the atmosphere, at or near the level of the sea, and which, at a height of three miles, would exert an internal pressure equal to about half a ton on every side. Will such pressure or resistance be due to its weight, inertia, gravity, or what? Mr. Cheverton afterwards tells us: "Still it is possible that compression and elasticity come into play with very low veloc-

ities." Mr. Cheverton's faith in his own assertions surely begins to waver; and, I believe, if he will study the subject a little further, he will soon become fully prepared either to deny or admit its existence altogether, and not partly acquiesce in an opinion involving his imaginary "serious error." In the meantime, I shall be happy to follow his advice as proposed, and if possible, "correct my views by practical experiment." Allow me, sir, also to return the compliment, and propose to Mr. Cheverton to withdraw his "balloon-directing" ideas from the question, and try for himself the experiments he suggested for my consideration; he may then attach such importance to the results as seemeth him best.

I am, sir, your obedient servant,
W. QUARTERMAIN.
10, Clarendon Place, Edgware Road.

THE WAVE LEVEL.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

Sir,—The wave line, as a water line for a ship's bow has been proved to be disadvantageous. Ships have had the concavity filled up and they have been improved by the alteration.

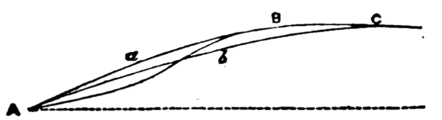
The sailing ship "Fiery Cross," which won the prize from China last year, bringing home the first teas, was designed, I believe, by Mr. Rennie; and the lines of her bow between the light and load water-lines are convex—I think they are parabolic curves.

I know of no vessel having the wave-line bow which is pre-eminently fast, unless her speed may be fairly attributable to her engines. In sailing vessels the wave-line may be said to have been fairly exploded. I also know of a yacht, designed by Mr. Russell himself, the property of the Duke of Sutherland, which vessel is now lying in the Victoria dock; and, although the production of that talented gentleman himself, she must, as regards speed, I am afraid be deemed a failure.

The bow-line, which will enable the vessel to pass through the water with a minimum of elevation to the fluid, appears to me to be the best line, but I have never seen a vessel with a wave-line bow under weigh without observing a great elevation of water at that part where the greatest concavity of curvature takes place, or where what a ship master called that d——d hollow in his bow.

The wave-line is a source of weakness, and it diminishes capacity. These considerations are important.

Those who argue in favour of the wave-line bow ignore the latter consideration. Let A B be a wave-line bow, and A a B a convex-line bow.



They argue as if the question were between those two lines, forgetting that with the latter there is a great increase of capacity and buoyancy; the former commercially advantageous, and the latter contributing to the structural strength of the vessel The real question would be between the wave-line and the inner convex line A b c. For this line would produce about the same capacity.

Now, if any gentleman, having a vessel distinguished for her speed, with a wave-line bow will be kind enough to state her name, I will undertake to design a vessel which shall beat her in speed, with *the same* capacity, length, breadth, and depth. Perhaps the above illustration will be sufficient to indicate to your readers why I should be able to do so.

I say nothing of wave or concave lines below the water-line, they are indispensible, and every practical naval architect knows why.

NAUTICUS.

THE STRAIGHT LINE *VERSUS* THE WAVE LINE FOR VESSELS.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

Sir,—It is with great pleasure I recognise in Mr. Young the candid disposition which enables him to perceive, and, yet more, to acknowledge, his misconception on one point of my observations on this subject If the same estimable quality of mind had been conjoined with a little more attention, it would have preserved him also from the misapprehension of supposing that, whilst alluding to the form of a fish as affording a better analogy for consideration in determining the shape of the bow of a vessel than "the glacial wave-line cutwater," I had failed to mark the distinction between a body floating on and wholly submerged in water. I thought I had sufficiently indicated, although in a word only to the wise, the respective conditions of human and piscine existence, and thence the necessity of some modifications in any form suggested by the analogy, when I said that "we wish to keep our skins dry, but fishes would rather keep theirs wet."

It would, however, be easy, from the contemplation of the heads of fishes, to argue very plausibly in favour of straight lines for the bow of a ship rounded off at their junction with her sides, but, in truth, I have little faith in conclusions derived from analogies, except in regard to certain leading principles, and those only in the abstract; for nature herself, in their application, subordinates them, more or less, to the conditions or exigences of the several varieties of existence, even down very near to particular cases. The pike and the carp have their forms determined in accordance with the nature of their food; and whilst the principle of the inclined plane for the diminution of resistance is obvious enough in the one case, because it is a fish of prey and requires to move with great velocity, in the other, judging at least by the outlines in elevation, the principle would almost appear to be ignored. The whale presents a more glaring instance of departure from principle, doubtless in fulfilment of high purposes, and in obedience to a higher law in the domain of final causes. Man, indeed, in his contrivances, is less trammelled with conditions than nature, and is enabled to give a more perfect allegiance to principles, for his objects are narrow and exclusive, and working upon dead matter he is freed from the necessity of keeping up the vital continuity of parts. I advance, therefore, no argument from analogy on my side of the question. I merely retorted, that it would be more to the purpose, from that point of view, to select the form of a fish after which to fashion the bow of a vessel than nature's "wave-line glacial cutwater." And yet it is not wholly undeserving of notice, that the heads of fishes are not in any instance, to my knowledge, moulded with hollow lines, although a prolongation of the snout, in a few cases, may present a short filled-up inward angle at the juncture with the head.

I have adverted to the subordination of principles to circumstances, to which the *ultras* of all opinions are ever inclined to demur, except in cases special to themselves. Now, if any gentleman can show that there is more to be gained in matters of importance by the violation of principle, in choosing hollow lines in preference to straight lines, than there is by an adherence to it—and I do not say the thing is impossible—I will at once give up the point in dispute; for, though I admit the influence of principles according to measure, I disclaim the advocacy of any action therefrom absolute and without restraint, as being an exhibition of tyranny in the government of thought. But I must say, that at present the *onus* is on the other side, and that I am not bound to bring forward "other proofs," and "something better than" I have "hitherto done." However, I will think of it; perhaps a geometrical construction would be more convincing.

I cannot conclude without a few words on the "glacial wave-line cutwater." Mr. Young asks, in reference to my explanation of the mode in which a current operates to produce hollow lines, in this ice-formed exemplar for the bow of a ship—"What more can be wanted by way of proof that here we have the form of least resistance?" The least resistance—of what kind?—as involving least destructive action, or least mechanical action? By simply raising this destruction we arrive almost at once at a solution of the difficulty, but which did not more readily occur to Dr. Thomas Young, although a very practically-minded philosopher, than it has done to Mr. Chas. F. T. Young. I have already admitted the first alternative, but have contested the second, which comprises the real point in dispute—the comparative expenditure of power as depending on form. But is the distinction valid? Does not the first-mentioned action follow as a consequence for the second? Certainly; but the second action is not necessarily less because the other is less, and this is the gist of the point in dispute; for there are conditions on which the effect depends existing in the one case which do not exist in the other. Imagine the cutwater to be of adamant, and the effect vanishes altogether, and along with it the proportionality of its mechanical cause. But, suppose the materials of the cutwater to remain the same, and to vary only in form, still there is no proportionality between the mechanical action, the cause, and the destructive action—the effect. The same elements of strength, simply by a different arrangement of them, may be made to withstand a force which otherwise would overpower them; and this increase of efficiency, by the very fact, negatives rather than necessitates the conclusion that the assailing force must have been virtually lessened by such change of form, in consequence of being deprived thereby of some advantage in the attack. On the contrary, the fact might be quite consistent with the force being greatly increased on account of it; and this happens to be the case. Less resistance, of a kind involving destruction in detail, is perfectly compatible with a greater resistance being required to oppose a movement in the mass. Even in a case where the resistance is of the same kind; where, for instance, a given weight of materials is arranged in the form of a hollow cylinder instead of a solid one, a greater strength might be gained in this way, although a greater strain should be brought upon the cylinder through the extension, within limits, of the length also in the alteration of the form. A favourable balance in the profit and loss account on the side of durability in the cutwater is much more likely where the effects produced, instead of being homogeneous, concern things so diverse in nature as attrition and inertia. The admission, therefore, of either of the above alternatives does not establish the other, and accordingly, a vessel with hollow lines, although exposed to less abrasion, if that were anything worth caring about, might only all the more have to contend with resistance of a retarding kind; whether she actually would or not, depends on another independent line of argument, which I have heretofore gone over. I am only showing now, that less destructive resistance does not necessarily imply less mechanical resistance.

Yours, &c.,
BENJ. CHEVERTON.
Sept. 15.

PROTECTING SHIPS' SCREWS.

TO THE EDITOR OF "THE MECHANICS' MAGAZINE."

Sir,—With reference to the notices which you have been so kind as to make of my Screw Protectors, I beg to communicate to you what must be considered very interesting information on this subject. It is believed that the suspension of the propelling power of the Confederate Steam Ram "Arkansas," and which finally led to her destruction, was owing to the Federals having led her amongst warps purposely laid out to entrap her, and which, being taken up by her screw, soon rendered her motionless. In that helpless state she drifted on shore, and the *finale* we have clearly stated in the public papers. To prevent her getting into the hands of the enemy, a slow match and train to the magazine were arranged; the crew left the ship; and in a few minutes this hitherto impregnable ship was blown to pieces! Here was a powerful engine of war, that had caused the greatest consternation amongst the Federal squadron—a few days before defying the heaviest cannon that could be brought to bear upon her from ten times her own force, and indeed holding triumphant sway, *so long as the propelling power of her screw was in existence.* Mark this: but when that vital part was touched—by what?—not by a powerful Armstrong or Whitworth butt—not by any costly engine of war of that description—but by a few fathoms of (rope!) this dreaded monster becomes helplessly disabled, and falls an easy prey to her enemies! Now this is very striking, and cannot fail to suggest anxious considerations regarding our own costly ships of war. The same efficient means used in the disabling of the "Arkansas" can be used in a far more extensive and deadly manner than I am persuaded is generally supposed. I have already designed most comprehensive arrangements, whereby I have no question in my own mind, approaches to harbours can be protected against the passage of screw war-ships most completely; that is, provided the screw remains in its present unprotected condition. There is no provision at present to protect the screw against hawsers and warps. It is true that an impression is entertained by many naval officers, that the velocity and power of a screw propeller are such as to enable it to cut through any impediment in the shape of hawsers. A plan has also been suggested to extend the cutting power of the screw, by bringing it close up to the stern port, and forming the foremost edge of the screw into a scissor-like shape, so as to make it act as a shear to cut through hawsers, &c., and to assist this effect by doing away with the after beams, to enable the screw to clear itself of the severed parts of the hawser. I cannot help believing, however, that it is unwise to depend on such means to protect the screw from fouling, and I have my doubts, too, that

this will have any effect at all under certain circumstances. In the first place, to obtain the necessary cutting power that is to sever a hawser of large size, say a seven or eight-inch hawser, the s rew must have at the moment considerable velocity. That supposing the ship should have slackened her speed, or at the moment that the hawser fouled the screw she had only commenced to turn a-head, the screw, of course, moving very slowly, then I believe it admits of great doubt if the screw would succeed in cutting a hawser of any considerable size. Dealing also with chain. It would not be difficult to employ this for purposely fouling the screw of an adversary, and in that case I have my further doubts of the efficiency of their cutting arrangements. In smaller vessels, too, such as gun-boats, where the cutting energies of the screw would be more feeble than in larger ships, it may be questioned if this means for clearing the screw could be depended upon. A particular kind of screw must also be employed. A propeller of the Griffith description would surely not do.

I maintain, therefore, that the most efficient and reliable way of dealing with the subject, is to provide means for preventing hawsers or warps getting to the screw at all; and, until ships of war are provided with means for accomplishing this object, they are in a delutive condition to meet the casualties incidental to modern warfare. Now, I maintain, that the simple and inexpensive means which I have produced fully provide for the desired want. My hawser-guards bid entire defiance to hawsers, warps, &c., encountered in the manner they would be in warlike operations. It is impossible to foul the screw with my guards. This has been most decidedly proved by the experiments I have made at Portsmouth; and with this immense addition to the defensive powers of the screw war ship, is also the striking feature in my invention, that the protectors, when not required for use, do not in any way affect the efficiency of the ship with reference to speed and steering powers. Indeed, even when the protector is down, it offers very little impediment to the ship's progress through the water. The radius bars being made of flat iron, oppose a very thin edge to the water, and the guard-chains offer a very slight resistance. I believe that in a frigate of the Shannon class her speed would not be diminished a knot and a-half by the application of the protector, and there would be little or no influence exerted in the steering powers of the ship. I beg also to allude to the extreme simplicity of my invention. It can be applied to a ship in a few hours, and, if need be, taken off in half-an-hour. The experiments which I have lately made in regard to towing ships have also been very satisfactory. Our ships of war are frequently employed on this service, and it is always one of anxiety; for the least slackening of the towing hawser renders it liable to be taken up by the screw. I find, however, that my guards effectually prevent this, and a captain would be able to perform this service with much greater confidence, and even ability, than can be done at present.

I am strongly impressed with the belief that the subject I have taken up is one of the deepest interest to modern navies. Until the screw propellers of ships of war have protective provisions against hawsers, warps, &c., they are not, as I have before said, in an efficient condition to meet the casualties to which they may be exposed. Perfect as their artillery may be—impervious as their sides may be—costly and perfect as all their provisions of war are, still there is that vital part—the screw—at present unprotected and apparently uncared for; and which, at once neutralizes the value of all other power. The disabled and lost "Arkansas" reads us a lesson it would be wise not to lose sight of. We cannot tell what services our ships might be employed upon in the event of another war. We saw during the Russian campaign that men-of-war frequently went up rivers and other confined waters, admirably adapted for using screw-fouling means against an enemy; and it has often been a marvel to me that, with all the ingenious contrivances provided by the Russians for crippling our ships, they had never thought of, or at least tried, means for fouling the screws. The story of the "Arkansas" will, however, suggest the employment of such means for the future.

I must ask leave to be permitted to address you again on this and some other kindred subjects, and

I remain, Yours obediently,

H. D. P. CUNNINGHAM.

Bury House, near Gosport, 10th Sept., 1862.

During the past week the number of 15 wrecks was reported, making a total for the present year of 1,193.

Correspondence.

[We do not hold ourselves responsible for the opinions of our Correspondents.]

EXPLOSIVE BULLETS.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

Sir,—In the "Scientific American" of the 6th inst. there is a letter on explosive bullets being used by Southern Americans in the present unhappy war, and the editor's note on it is as follows:—"Explosive bullets are old and well-known, but for some reason, probably owing to their expense, our Government has not used them. They were used in the Chinese war to set fire to ammunition trains."

I enclose the letter of Gen. Sir Richard Airey, which was embodied in my memorial to H.R.H. the Commander-in-Chief, proving that I invented the rifle explosive shell as far back as the year 1823, and also the report of the select committee at Woolwich, dated September 4, 1826.

I am, &c.,

International Hotel, J. NORTON.
Bray-street, Wicklow,
September 15th, 1862.

The following is the report referred to:—

Office of Ordnance,
Sept. 4th, 1826.

Sir,—I am directed by the Master-General to acquaint you that the Select Committee convened for the trial of the rifle shell of your invention, have reported their opinion that these shells, although they would probably fulfil your expectations of exploding the powder contained in tumbrils or carriages, could not with advantage be introduced into the service as part of the ammunition of Rifle Corps.

I have the honour to be, Sir,
Your obedient servant,
Captain Norton. FITZROY SOMERSET.

TO CORRESPONDENTS.

Received—W. de St. C., T. L. and Son, J. C. and Co., W. C. P., E. B., Capt. N., Capt. S., I. H. D. W. T. T., N. W., J. R., W. T., W. P., An Aspirant.

GOSSIP.

The French Minister of Marine has just issued a circular recommending the captains of merchantmen to protect their vessels with lightning conductors.

The project for establishing steam communication between Australia and England *via* the Cape of Good Hope, is gradually assuming shape.

Workmen have commenced to erect the new railway station at North Shields, for the Tynemouth branch of the Blythe and Tyne railway. It will be close to the House of Correction, and adjoin the turnpike road, and will be much more convenient for the North Shield people than the present station.

Admiralty orders have been received at Chatham dockyard for eight new vessels of war of various rates and tonnage, from a 4-gun vessel up to a 91-gun line-of-battle ship, to be built at this dockyard as soon as vacancies arise on the several building slips.

At the inquest of the death of a lady in the Crystal Palace branch of the London and Brighton Railway, Mr. Humphreys, the coroner, said, in his summing up, what the public had reason to complain of was that, whether the driver of the pilot engine had authority, or had not, to start without permission, he was enabled to enter on the main up line without any mechanical check whatever. If the traffic on the line were so enormous that it was impossible to give time for a passenger train to enter the London station before empty carriages were brought out to be shunted, some means ought to be devised which would prevent the driver of a pilot engine from entering on the main up line without the permission of the signalman. It appeared to him that, under the existing system, a miscalculation in time to the extent of half a minute, or a miscalculation in the pressure of steam to the amount of half an ounce, might be the means of carrying the driver of a pilot engine beyond the point, and so jeopardize the lives of a train full of people. It would seem that in their shunting arrangements the company, to use a homely but expressive phrase, sailed a little too close to the wind. If they did not wish to change the system they must only take the consequences.

A monster album, manufactured by M. Rollinger, of Vienna, originally intended to receive the autographs of all distinguished visitors to the Exhibition, has been offered to, and accepted by, the corporation of the city of London. The album is six feet long, three and a-half feet wide, and about eight inches thick. In the centre of the upper corner are the City arms, and in metal panels at each side are engraved the emblematic rose, thistle, and shamrock. Other panels are formed of mosaic leather, arranged with great taste, and with a marvellous amount of care. The inside of the book is lined with a rich moiré silk, every page has a border of rich gold and delicately-coloured ornamentation, and the weight of the book is upwards of 700 lbs.

On Thursday week, a new park was opened at Glasgow, on the south side of the river. The Park, which is named after her Majesty the Queen, comprehends a superficial area of 143 acres, although only about 60 acres have been put in proper order.

The railway from Fribourg to Lausanne, in France, has just been opened. The most remarkable feature of this line is, the lofty viaduct of Grandley, made of iron from the foundry of Creusott, which crosses th same at a height of 78 metres from the water and is 333 metres in length.

An Edinburgh paper says:—"A somewhat unusual incident occur ed on Wednesday in the neighbourhood of Croy station, on the Edinburgh and Glasgow Railway. A number of workmen were engaged boring for minerals, and when they reached the coal seam a stream of gas issued from the bore, which, on being lighted, burned to a height of nearly nine feet. The supply of gas was so abundant that it continued burning throughout the day."

"The common experiment," says the *American Journal of Science* "of pouring iron filings into water slowly boiling into smooth glass vessels to increase the ebullition, can be instructively varied by substituting powdered ice or granular snow for the iron filings. Snow that has thawed partially and then frozen, so as to become hard and granular, is the best; but powdered ice will answer, if kept so cold by freezing mixture as to be perfectly dry. If a spoonful of this ice or snow be thrown into a smooth flask nearly filled with water slowly boiling, intense ebullition at once takes place, a portion of the water being thrown out of the flask. The particles of ice thus act like particles of iron or sand, before they have time to melt and set free the steam."

The iron trade of South Staffordshire continues to present increased activity. At several works orders for certain kinds of iron are declined at the prices previously accepted, and most of the works are now in full operation. For ordinary merchant bars there is not an active demand, but the price is firmer. Pig iron is decidedly dearer, and a good many sales have been effected at an advance of 2s. 6d. per ton on the price paid at the beginning of the present or the end of the last quarter. Best native hot-blast brands are at £3 5s. to £3 7s. 6d.; cinder iron, £2 12s. 6d., with a gradual range between these prices. The attendance at the meetings last week was good, and the manufacturers were in better spirits, though the advance in pigs, without a corresponding increase in manufactured iron, was considered to be perplexing. Scotch pigs maintain the advance, the price yesterday being 55s. 6d. cash.

The forthcoming meeting of the British Association for the Advancement of Science, at Cambridge, promises to be a prosperous one. The first general meeting will be held in the town hall on Wednesday, Oct. 1, at eight p.m., when William Fairbairn, Esq., LL.D., F.R.S, will resign the chair, and Professor Willis will resume the presidency, and deliver an address. The various sections will assemble in the rooms appointed for them, for the reading and discussion of reports and other communications, on Thursday, Friday, Saturday, Monday, and Tuesday, Oct. 2 to 7, at eleven a.m.

It is said that the contractors of the Rome-Naples railway continue to urge on the Vatican the great advantage of bringing the two cities within eight hours of each other, but without success.

The Newcastle monument to George Stephenson, our great engineer, is completed, and will shortly be inaugurated. It has been erected in Neville-street, and consists of a massive stone pedestal, bearing a colossal statue of George Stephenson, by Lough, together with certain emblematical figures, viz., that of a blacksmith, naked to the waist, sitting and leaning against an anvil, while his right hand grasps a hammer; a pitman carrying a "Geordie" lamp; a platelayer holding a model of Mr. Stephenson's old fith-bellied rail; and an engine-driver leaning against a locomotive. The monument to the late Robert Stephenson will be placed nearer to the railway station.

Mr. George Bourn says:—"The remarks of Dr. Robert Angus Smith, at page 150, of Sept. 5, quite accord with my ideas of explosion with

paraffin, &c. If I wished to cause an explosion, I should get two cans, one empty and the other full, and put a large funnel in the empty one, then place a lighted candle a few inches above the nozzle of the empty one, at the side of the funnel, and then pour from the one into the other; by so doing, the air and gas would be driven out against the flame of the candle, and if there were no explosion, I should be quite disappointed. If such an experiment were tried in a room, I am strongly inclined to think there would be a *double* explosion."

The second annual meeting of the Miner's Association of Cornwall and Devonshire, will be held at Falmouth on the 24th day of September, in the Council room of the Royal Cornwall Polytechnic Society, when papers connected with the subject of mining, during the operations of the Association will be read.

On Thursday next, Messrs. R. Steel and Son, of Greenock, launched from their building yard a vessel of 480 tons o. m., for Messrs. Charles Saunders and Co., Liverpool. Her dimensions are—150 feet length of keel, and 16 feet 9 inches deep.

On Monday last, the contractors commenced operations in Old-street-road, St. Luke's, in connexion with the great Middle Level Sewer through Shoreditch, which will come out at Old-street. In the High-street a connexion is being made simultaneously with the main line of sewer from Bethnal-green, so as to continue the system through Old-street, *via* Wilderness-row and Clerkenwell to Bloomsbury, where it will unite with the western main drainage at Oxford-street. The works at the East London end present some formidable engineering difficulties.

Messrs Samuda, of Blackwall, are now busily engaged in the construction of floating-docks, iron steam-vessels, &c., for the Peruvian Government, with a view to the more complete navigation of the river Amazon, and to develope the resources of the vast region on the Atlantic side of the Andes.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

THE Abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following Table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved, and combined with all the advantages of a division into classes. It should be understood that these abridgements are prepared exclusively for this Magazine from official copies supplied by the Government, and are therefore the property of the Proprietors of this Magazine. Other Papers are hereby warned not to produce them without an acknowledgement:—

STEAM ENGINES, &c., 546.
BOILERS AND THEIR FURNACES, &c., 570.
ROADS AND VEHICLES, including railway plant and carriages, saddlery and harness, &c., 573.
SHIPS AND BOATS, including their fittings, 545, 552.
CULTIVATION OF THE SOIL, including agricultural and horticultural implements and machines, 565, 587, 598.
FOOD AND BEVERAGES, including apparatus for preparing food for men and animals, *None.*
FIBROUS FABRICS, including machinery for treating fibres, pulp, paper, &c., 548, 563, 576, 580, 584, 590, 590.
BUILDINGS AND BUILDING MATERIALS, including sewers, drain-pipes, brick and tile machines, &c., 539, 542, 566, 592.
LIGHTING, HEATING, AND VENTILATING, 544, 555, 571, 577, 578.
FURNITURE AND APPAREL, including household utensils, time-keepers, jewellery, musical instruments, &c., 540, 541, 549, 551, 554, 556, 558, 567, 568, 569, 588, 591, 593, 597, 599, 606.
METALS, including apparatus for their manufacture, 557, 561, 575, 581, 585.
CHEMISTRY AND PHOTOGRAPHY, &c., 564, 574.
ELECTRICAL APPARATUS, &c., 538, 562, 594.
WARFARE, &c., 572, 589, 595.
LETTER-PRESS PRINTING, &c., 582.
MISCELLANEOUS, 536, 537, 543, 547, 550, 553, 559, 560, 579, 583, 586.

536. W. SMITH. *Improvements in the method of making cigarettes, and in the apparatus and materials to be employed therein.* (A communication). Dated Feb. 27, 1862.

Instead of employing cigarette paper folded and inserted inside the cylinder, the patentee prepares sheets of the paper, or other material of the requisite size, and forms books of them by placing them one in advance of the other. He then gums a broad part forming the overlapping pieces, thus securing one edge of each sheet to the next. When it is required to make a cigarette, a sheet of this paper, having on one of its edges a strip of gum, is placed around the outside of the cylinder, and upon the edge being moistened it adheres and forms a tube or case. The tobacco is then charged into the cylinder in the ordinary way, and the end of the paper tube extending beyond the cylinder being secured, the rammer is used to force the tobacco into the cigarette case or tube. The cigarette is then completed. The apparatus is provided with an external leathern or other case, which may be made to contain the paper, tobacco, fusees, and the machine. *Patent completed.*

537. J. TANGYE. *An improvement or improvements in hydraulic lifting jacks.* Dated Feb. 27, 1862.

This invention is not described apart from the drawings. *Patent completed.*

538. Sir C. T. BRIGHT. *Improvements in electric telegraphs and in apparatus connected therewith and employed in the manufacture thereof.* Dated Feb. 27, 1862.

This invention will be specially noticed in a future number. *Patent completed.*

539. T. BRAY. *Improvements in ornamenting wood in imitation of inlaid work.* Dated Feb. 27, 1862.

For the purpose of this invention, the patentee proceeds as follows:—He coats the surfaces to be ornamented, which should be of white or light-coloured wood, with a glutinous matter; after the glutinous coat is dry, he applies to the parts of the surface, which are to appear as white or light-coloured, a spirituous preparation of gums and other materials. The desired pattern or design having been traced on the surface, in this preparation, and the preparation applied being dry, he stains the whole surface with a water stain. *Patent completed.*

540. R. SEAGER. *Improvements in the manufacture of boots and shoes, and in apparatus employed therein.* Dated Feb. 29, 1862.

This invention consists in first producing a sole, or a sole with a heel, and then fastening the same to the upper, by which much less skilled labour is required than heretofore. For these purposes, when making a sole to which no heel is applied, or a sole with a heel thereon, suitable moulds are employed, within which the materials used are pressed into the desired forms. When leather is used, if only in one piece, the same is cut by a cutter into the proper shape; the leather is then moistened, and placed in a mould, and is subjected to considerable pressure therein, by which the leather will not only be rendered compact, and its grain rendered close, but the inner, as well as the outer surface, including the edges, will be made most accurately to the desired form. *Patent abandoned.*

541. T. R. FOSTER. *Improvements in the manufacture of bullion fringe or cord.* Dated Feb. 27,1862.

Hitherto, the bullion fringes or cords for cornices and furniture have been ordinarily manufactured by merely twisting the materials of which they are composed. Now, this invention consists in first weaving the materials into a fabric, and afterwards twisting the fabric, so woven, in order to form bullion fringes or cords. *Patent completed.*

542. W. S. WOOD. *Improvements in valves for regulating the flow of steam, water, or other liquids, and in means or apparatus for working or actuating them direct from the governor, or when worked by expansion cams in connection therewith.* Dated Feb. 27, 1862.

This invention consists of a duplex disc valve, or double disc valve with suitable openings or perforations therein, mounted upon a spindle passing through a stuffing box in a box or casing suitably formed with inlet and outlet ports, and arrangements for connecting the same to, or between, the conducting pipes. This duplex disc valve is placed between two disc seats, faces, or surfaces, one, or both, of which are capable of adjustment to obtain proper jointing or fitting thereof to the faces of the valve. Steam, water, or other fluids may be admitted, either between the two discs or faces of the valve, and pass through the openings thereof, and of the seats, when such openings are placed opposite to each other; or such fluids may be admitted, and pass through the openings of the seats, and thence through the openings of the valve. The valve is caused to turn upon its axis by means of a lever fixed on the spindle thereof, and actuated by the governor, thereby opening or closing the apertures of the valve and seatings. *Patent completed.*

543. J. REVELL. *Improvements in oil cans.* Dated Feb. 27, 1862.

This invention consists in the construction of improved oil cans, in which screws, corks, or other parts hitherto connected with the feeding portion of the can, are dispensed with, unless desired for the purpose of removal when cleansing the interior of the cans. These improved oil cans are made of any required shape, and they each consist of two main divisions, one the upper part, or air chamber, and the other the lower part, or chamber for containing the oil. The upper part is separated from the lower by a partition in the body of the can, and contains the air which passes through a feeding tube, fixed to the partition, and extends to nearly the bottom of the oil chamber. The delivery tube or spout of the oil can passes from the underside of the partition through, or past the air chamber, and is made of any required length. With these improved oil cans there is no possibility of leakage, and the oil will not escape if the can should, by accident, fall to a horizontal position. *Patent completed.*

544. P. D. AZEMAR. *An improved mechanical arrangement for the winding-up and the setting of the hands of watches by means of the knob of the pendant.* Dated Feb. 28, 1862.

This invention relates to a mechanical arrangement for the winding up and the setting of the hands of watches, by means of the knob of the pendant instead of by a special watch key, thus entirely doing away with the use of this latter, the said arrangement, (called remontoir), forming part of the watch, and being contained with the ordinary movement in the casing of the watch; so that, at the outside, a watch provided with this remontoir offers no difference to an ordinary one, except the pendant knob and a small stud protruding through the rim of the casing. The invention is based on the application, for this purpose, of a three-armed or crutch lever, an endless screw or screws for actuating the minute hand pinion, and the main spring arbor in combination with a Brequet key clickwork, and other suitable parts, in such manner that by turning the knob of the pendant the watch may be wound up without acting on the hands; whereas, by pressing at the same time on a stud protruding through the rim of the watch, the turning of the pendant knob will cause the hands only to move, thus allowing the setting of the same as required. *Patent completed.*

545. W. H. MUNTZ. *Improvements in paddle-wheels.* Dated Feb. 28, 1862.

These improvements apply to the ordinary radial form of paddle-wheel employed for propelling vessels, and consists in affixing the floats of such paddle-wheels to the arms lengthwise, instead of across the face of the wheel as usual, the floats being narrow, and in length about two-thirds of the radius of the wheel. Each arm of the wheel may carry its own float, or the floats may be attached to each alternate arm. Each wheel may be composed of only one set of arms and floats, with their corresponding rim and boss, or of two, three, or more sets of arms, floats, rim and boss, keyed side by side on the shaft, and braced together by diagonal or other tie rods. *Patent completed.*

546. A. W. MAKINSON and W. F. BATHO. *Improvements in locomotive engines.* Dated Feb. 28, 1862.

The objects of this invention are to reduce the oscillatory motion which occurs in locomotive engines of the ordinary construction when running at speed; to reduce in number and simplify the working parts of the engine; and to reduce the friction and resistances to onward motion. To effect these objects, and to adapt the engine to the requirements of actual traffic, the patentees construct the engine with one cylinder only, which they place in the mid-section of the engine, the piston-rod, cross-head, and half the weight of the connecting rod by weights, having a reciprocating motion in an opposite direction to that of those parts; and they enable the driver of the engine readily to start it at whatever part of the stroke the piston may be. *Patent completed.*

547. J. C. RATLIFF. *Improvements in the covers for bindings for books and blotting cases.* Dated Feb. 28, 1862.

This invention consists in making the covers or bindings of books, ornamented by the use of woven figured fabrics, either of silk, cotton, wool, hair, or other fibrous material. *Patent completed.*

548. G. MCKENZIE, W. F. MURRAY, and J. HAMILTON. *Improvements in machinery or apparatus for the manufacture of bobbins or holders for textile materials.* Dated Feb. 28, 1862.

This relates to the arrangement and construction of machinery or apparatus for moulding bobbins from clay, which improvements are based, to a certain extent, upon a previous invention, for which Letters Patent were granted to the said Geo. McKenzie and John Hamilton, bearing date the 26th day of November, 1860. According to the present invention, the dod or cylindrical piece of clay to form the bobbin is first made by pressing the clay through an aperture of the proper diameter, and is then moulded by means of four moveable dies or moulds, which form the external shape of the bobbin, whilst the tubular aperture through the centre of the bobbin is formed by a self-acting spindle which passes through the dies that form the ends of the bobbin. *Patent abandoned.*

549. J. POLLOCK. *Improvements in apparatus for protecting trousers from mud.* Dated Feb. 28, 1862.

This consists in attaching a shield to the hind portion of the heel of a boot or shoe, whereby the mud which is raised in the act of walking is caught by the under side of the shield, in place of being thrown on to the legs of the trousers. *Patent abandoned.*

550. J. L. CHARCOUCHET. *Improvements in machinery for breaking stone.* Dated Feb. 27, 1862.

This invention consists of a new method of breaking stone by machinery, worked by steam or other motive power. A strong cast-iron frame-work contains, or encloses, a sifting apparatus formed by a series of parallel bars of the shape of prisms, on which the stone to be broken is placed. The sides of the sifting apparatus are firmly bolted to a timber frame, to the longitudinal cross timber of which a powerful hinge is fixed, whereon two moveable anvils work underneath the sifter. These anvils have grooves or channels cut on their faces so as to correspond with the bars of the sifter into which they fit when the anvils are in their uppermost or horizontal position. These anvils are raised to a horizontal position, and lowered alternately to an angle of about 45°, by means of eccentrics, working on a shaft at the top of the cast-iron standards of the machine. From these eccentrics connecting rods descend, one on each side of the machine, and are attached by hooks to the hammers. Above the hinges of the anvils a broad leather or steel band passes over a copper pulley, and is attached to the hinged extremity of the anvils by means of a projection or stop running along the ends of the channels. Two cranks on the same shaft, which works the eccentric, give a vertical reciprocating motion to two connecting rods, at the lower end of each of which a heavy block or hammer is attached. These hammers, aided by guides in the standards, are consequently caused to descend upon the stone placed on the sifters and moveable anvils. The stone is thus broken into pieces, the size of which may be regulated according to the spaces between the bars of the sifters. *Patent completed.*

551. R. A. BROOMAN. *Improvements in the manufacture of hats and bonnets.* (A communication.) Dated Feb. 28, 1862.

This invention consists, first, in making hats with a body of felt, and with the outer covering of silk plush; and, second, in making hats with a body of felt or felted fabric, and with a covering of felt or of felted fabric. *Patent abandoned.*

552. J. PARKER. *An improved mode of applying steam as a motive power for propelling vessels and for other purposes.* Dated Feb. 28, 1862.

The first part of this relates to a previous patent, dated Oct. 2, 1860, and which consists in discharging high-pressure steam into a pipe or tube of uniform diameter, and leading through the bottom of the vessel at or near the stern into the water. The present invention consists in using super-heated steam, of whatever degree of pressure, instead of high-pressure steam in its natural state of saturation. The invention also consists in the construction and combination of the steam jets, and of those parts into which the steam is discharged, and through which the air

is forced into the air-pipe or chamber leading to the water. *Patent completed.*

553. T. Cowburn. *Improvements in apparatus for raising and discharging boiling soap, and for dividing the same into bars when congealed.* Dated March 1, 1862.

These improvements consist in raising boiling soap from the pan in which it has been boiled to the required level by a vessel containing a self-opening and closing valve, to admit and discharge the boiling liquid, which vessel is raised and lowered by a suitable friction-hoisting apparatus, driven by a separate steam-engine or otherwise, and consisting of a paper or other bowel acting on a friction wheel, which is nearly surrounded by a break clip; the barrel for the rope or chain is connected to the friction-wheel, which is brought in contact, or moved out of contact, with the paper or other bowel by a lever. *Patent abandoned.*

554. J. Bradford. *Improvements in washing-machines, for cleansing domestic garments, fibrous materials, and for manufacturing purposes.* Dated March 1, 1862.

Here the patentee uses one or more eccentric or round rollers, and drives them by hand, or steam, or water power, each of which rollers has one or more ribs or projections running longitudinally from end to end, and revolves in an oblong, square, or other suitably shaped washing-tub or vessel, in which vessel he places frames underneath roller or rollers for supporting one or more elastic rollers, between which and the aforesaid round or eccentric roller or rollers the materials to be washed are carried and rubbed by the projections, the elastic roller yielding to the pressure of the round or eccentric roller or rollers, and thereby regulating themselves to the various thicknesses of the fabric acted upon. He also, when required, covers the round or eccentric roller or rollers, or the projections upon them, with india-ruber, or other elastic material, so as to be adapted for various washing purposes, or he makes the rollers entirely of india-rubber. When one round or eccentric washing-roller is used, he works it, when desired, with a foot-treadle and fly-wheel, so as to leave the hands of the operator at liberty. He also places in the washing-tub or vessel a cage or perforated box, and traverses it to and fro from one end to the other, in order to supply the fabric or material to the elastic rollers, and receive it from them. *Patent completed.*

555. J. Sim. *Improvements in the construction of gas-meters.* Dated March 1, 1862.

This relates to certain improvements applicable to the construction of wet gas-meters, the principle upon which it is chiefly founded being that of causing the gas to pass over or come in contact with an extended surface of water in a separate vessel or vessels, whereby it takes up and absorbs, or becomes saturated with, moisture previous to being admitted into the measuring compartment of the meter, and thus preventing the absorption of the water contained therein by the gas, as is the case when the latter is introduced in a dry state, the effect of such absorption necessarily being to alter the level of the water contained in the measuring compartment. The water contained in the separate vessel or vessels is also constantly evaporating, the results of such evaporation passing upwards into the measuring compartment, and thus assisting in preserving the water level therein. *Patent completed.*

556. H. C. Muller. *Improvements in the manufacture of imitation bearskin caps.* Dated March 1, 1862.

The inventor takes racoon skins, and dyes them jet black to the roots, then shapes the skin and forms the imitation bearskin cap of any suitable shape, with the skin so disposed and arranged that the hair in its natural position inclines or stands upwards. He now treats the skin with a strong solution of linseed water, combing and brushing it well, and training the hair in the reverse direction to its natural inclination, causing it to fall down and stand straight out from the cap, which presents the appearance of the real bearskin cap. *Patent abandoned.*

557. M. Dodds. *Improvements in machinery for moulding, forming, or shaping articles of iron or other malleable metals, and for shearing or cutting such metals.* Dated March 1, 1862.

This has reference to a previous invention patented, dated 8th August, 1860, according to which invention the machines for moulding, shaping, or forming articles of iron and other metals, are provided with a pair of rolls, and the axes of the rolls carrying the swages are geared together by means of toothed wheels fixed upon their ends. In order that the swages or operating parts mounted upon these rolls may act with precision, the patentee causes the axes of the rolls, in place of being geared together by toothed wheels, to be each provided with a crank, and those two cranks to be connected by rods with a parallel or other suitable motion, operated by a driving axis or other motive power, to give a partial rotary motion to each of such axes; by which means, whenever motion is given to one axis, motion will also be simultaneously given to the other, so as to ensure the operating surfaces of the swages acting in unison. There are other features included. *Patent completed.*

558. R. H. Boyer. *Improvements in the manufacture of of boots and shoes.* Dated March 1, 1862.

This invention refers to the manufacture of half or ankle boots and shoes, and consists in making the uppers entirely without seam, as hereafter explained. The invention takes a piece of leather of a size suitable for the intended boot or shoe, and renders it supple by soaking in water or other suitable liquid. He then removes it from the water, and while still wet, by means of a forked lever, presses it into contact with every part, except the bottom or sole, of a last, which is the counterpart of the boot or shoe to be manufactured. He then secures the edges of the leather to the bottom of the last, and when dry, or nearly so, the blocked upper is ready for the reception of the well and sole, which may be applied by pegging or sewing. Springs may be inserted in the uppers, for which purpose incisions must be made to admit them. *Patent abandoned.*

559. P. J. Guyet. *Improvements in taps or valves.* Dated March 1, 1862.

This invention is not described apart from the drawings. *Patent abandoned.*

560. M. and A. Gabriel. *Improvements in the bases of artificial teeth.* Dated March 1, 1862.

Here the inventor forms a compound of india-rubber, sulphur, phospate of lime and soda, in the following proportions: India-rubber 7 parts, sulphur 2, phosphate of lime 2½, soda 2; so as to form a substance that will give a representation of the natural bore, and at the same time resist the action of the acids of the mouth and stomach. The compound is then moulded and hardened by a well-known process, and being adapted and polished after the usual method, the entire piece is submitted to the action of a powerful electro-galvanic battery, for the purpose of depositing a thick coating or envelope of pure gold over the entire base, or in such parts only as may be required by the peculiarities of the case. *Patent abandoned.*

561. S. Hagne. *Improvements in machinery or apparatus for raising hammers and stamping with them hot or cold metals.* Dated March 1, 1862.

The specification of this invention comprises much detail, which we cannot give space to here. *Patent completed.*

562. A. E. Ragon. *Improvements in electrical alarums for telegraphic pressure.* Dated March 1, 1862.

This consists in constructing electric alarums with differential wires, for the purpose of destroying all residuary magnetism, and for rendering the same instrument so delicate and sensitive as to obtain during the transmission of the electric current the maximum of effect of the "line battery." This destruction of the residuary magnetism dispenses altogether in this alarum with the necessity for using any kind of regulating or winding mechanism; at the same time, the adjustment of the alarum is not in any way deranged or affected by the wood stand on which the alarum is mounted and fixed. *Patent completed.*

563. A. Potts. *Improvements in machinery or apparatus for scutching and refining flax, hemp, and other vegetable substances.* Dated March 1, 1862.

This consists in certain novel and improved combinations and arrangements of machinery or apparatus designed for performing the operations of scutching and refining flax, hemp, and other fibrous vegetable substances; and in so constructing the said machinery or apparatus, and combining the several parts thereof together, as to effect the scutching of the fibrous substances—first, by operating on both sides thereof at one time; second, by holding the fibrous substances, suspended during the scutching thereof, and at the same time advancing the said fibrous substances in a horizontal rotary direction; third, in reversing the position of the fibrous substances, or, in other words, causing one part of the machinery to operate upon the exposed parts of the suspended fibrous substances, and then causing another part of the machinery to take hold of the scutched portions of the fibrous substances, and let fall and hold downwards the upper ends of the unscutched parts of the fibrous substances, and afterwards to scutch those parts thereof, and thus to operate upon the whole length of the fibrous substances in one and the same machine. *Patent completed.*

564. P. Robertson. *Improvements in treating yeast, and in the manufacture of ammoniacal salts, and a substitute for animal charcoal.* Dated March 1, 1862.

Here, in order to obtain dry yeast, which may be kept a considerable time without prejudice to its quality, the inventor first separates as much as possible by subjecting the yeast to the action of a centrifugal machine, to pressure, or otherwise, and then finally dries it in a chamber or vessel having shelves or supports, on which are placed trays containing sulphuric acid, chloride of calcium, carbonate of potash, Canadian potash or lime, so as to be surrounded with the shelves or supports having thereon the yeast to be dried. A vacuum is obtained in the chamber or vessel by exhausting pumps or otherwise, and in time the yeast will be completely dried. The yeast is then reduced to powder, and it is then fit for use. The powder may be stored in bottles or other close vessels. In using yeast, in order to manufacture ammoniacal salts and a substitute for animal charcoal, the yeast in a moist state is mixed with clay and carbonate of lime or chalk; the mixture is to be dried and then calcined. —*Patent abandoned.*

565. S. G. Reynolds. *Certain improvements in power-spading machines.* Dated March 1, 1862.

This invention is not described apart from the drawings. *Patent completed.*

566. J. G. Jennings. *Improvements in the construction of chimneys or flues.* Dated March 1, 1862.

This is applicable more especially to chimneys or flues used in connection with open fire-places. In order to prevent the smoke being forced out into the room in which the fire-place is situated by a sudden puff of wind descending the chimney, the patentee enlarges the chimney at a short distance over the fire-place, by building into the brickwork a chamber, made either of earthenware or cast iron, and having both an inlet and outlet passage corresponding in size with that of the flue. He prefers to make this chamber hexagonal, as it appears when in position in front and back view, and with flat ends. The inlet and outlet passages, also, which are generally opposite the one to the other, he prefers to form as sockets to receive the ends of earthenware pipes, of which he usually forms the chimneys or flues. The chamber may be made in one piece, and it is preferred so to make it, but it may be formed in two or more pieces if desired. The use of chambers in this way admits of the use of much smaller chimneys or flues than those usually employed in combination with open fire-places. *Patent completed.*

567. J. B. Kendall. *An improved horse-shoe.* Dated March 1, 1862.

This consists in an improved compound or duplicate horse-shoe, one part of which is secured to the hoof by nails in the ordinary way, and is intended to be removed only when the growth of the hoof renders it necessary, whilst the outer or supplemental shoe is made removeable, and is furnished with calks to prevent the horse from slipping. *Patent completed.*

568. L. Martin and O. Penfold. *An improved candle-lamp.* Dated March 1, 1862.

According to the construction of the ordinary candle-lamp, the heat of the flame and contiguous parts melts the candle more rapidly than is necessary. Now, the object of this invention is to obviate and overcome these disadvantages by the agency of a current or currents of air passing through or among the heated portions of the metal, and thrown upon the upper surface of the candle, whereby the melting of the same is, as it were, regulated or modified, and the due performance of the lamp ensured. *Patent completed.*

569. C. Booldს. *Improvements in fastenings for gloves.* Dated March 1, 1862.

This consists in letting one or more elastic gussets into the wrist of the glove, either in the middle part, the back, or at the side or sides thereof. *Patent abandoned.*

570. J. W. and F. Davis. *Improvements in apparatus for supplying feed-water to steam boilers.* Dated March 1, 1862.

This consists in an arrangement of pipes and valves for supplying the boiler with water. A self-acting steam valve is placed on the top of the boiler, and is actuated by means of a float supported on the surface of the water therein. As the level of the water in the boiler descends, the float actuates a lever in connection with the valve, and raises the same, whereby steam is admitted into the water supply reservoir, and the water therein is expelled into the boiler. *Patent completed.*

571. H. Bowen. *Improvements in gas meters.* Dated March 1, 1862.

This relates to the system or mode of maintaining the proper water level in wet gas meters, by compensating for the evaporation or other loss of water in the meter, and comprises much detail which we cannot quote here. *Patent completed.*

572. R. Shaw. *Facilitating the loading or charging of guns, rifles, fowling-pieces, or other firearms, by a more convenient way of placing the ramrod in position.* Dated March 3, 1862.

This consists in holding the ramrod in its place with the the larger or heavy end near to the stock of the firearm, thereby facilitating the loading or charging thereof. A convenient mode of performing the invention is by attaching a socket, provided with a spring to the stock, and another socket at the end of the barrel, and an open clip between the two; the ramrod is thus securely held between the two sockets, and stayed by the middle clip. *Patent abandoned.*

573. P. Remond. *Improvements in double-rim bridle bits.* Dated March 3, 1862.

This invention is not described apart from the drawings. *Patent completed.*

574. J. Bell. *Improvements in apparatus for distilling shale and other bituminous minerals.* Dated March 3, 1862.

In one modification of this apparatus there are two or more furnaces, one of which communicates with a central vertical flue, having formed round it an annular retort chamber, whilst the other furnaces communicate with flues outside of or encircling such retort chambers. A pipe or pipes is, or are provided, to convey away the volatile matters, and valved hoppers are arranged at the top of the retort chamber for the introduction of the minerals. The refuse or waste matters pass off by discharge tubes disposed between the furnaces, the bottom of the retort chamber being funnel-shaped at each place, to guide the matters into the tubes. The bottom mouths of these discharge tubes dip into tanks, which are filled with water to a height sufficient to seal the tubes, and the refuse is removed from the tanks as it accumulates. Fresh minerals may be applied gradually or at short intervals, and the process may be carried on continuously or nearly so. *Patent abandoned.*

575. A. and J. Sheldon. *An improvement or improvements in smelting furnaces.* Dated March 3, 1862.

Here the inventors have constructed a smelting furnace, in which there are two flues passing from the body of the furnace into the chimney or stack; in one of the said flues, being that contiguous to the smelting chamber, there is a damper conveniently situated, which can be lowered or transposed preparatory to or during the smelting process, which more effectually confines the spelter to the smelting bed or chamber, until the "yellow metal" is in a condition to be removed therefrom. Near the centre of the furnace, and inside it, there is another damper contiguous to the other flue before-mentioned, by means of which the smoke is released and regulated. *Patent abandoned.*

576. J. Schofield. *Improvements in looms for weaving.* Dated March 3, 1862.

This relates to means for letting off or delivering the warp from the warp beam as the weaving proceeds, and consists in applying and arranging apparatus so as to maintain uniformity of tension on the warp threads, and only to let off, deliver, or supply the said warp as it is taken up or drawn forwards by the introduction into the shed of the weft threads, and by the beat-up of the lay or batten. *Patent completed.*

577. A. Tevendale. *Improvements in the apparatus used in connection with cooking stoves and domestic fire-places for the manufacture and supply of gas.* Dated March 3, 1862.

Here the inventor distils coal or cannel, but he prefers common coal mixed with a small quantity of lime or oxide of iron, in an ordinary retort, and places the said retort in such a position that the waste heat from cooking stoves or domestic fire-places shall be economised for heating the said retort, providing suitable dampers, so that the waste heat may only act on the retort when desired. From the retort he caries a pipe or pipes into a suitable vessel to receive any condensed matter thence direct to the burners. He provides, in addition to the foregoing, a pipe for carrying off the steam and other incombustible gases given off immediately after charging the retort, and for permitting the escape of any extra pressure or surplus when a supply is no longer desired. *Patent abandoned.*

578. T. Zillano. *An improvement in purifying gas.* Dated March 3, 1862.

This consists in the use of oxide of manganese, in combination with lime, and with sawdust, or cocoa-nut refuse, or ground bark, as an auxiliary filtering agent. Or, instead

of sawdust, other ordinary filtering agents may be used in combination with the oxide of manganese and the lime. *Patent completed.*

579. A. BEDBOROUGH. *Improvements in pillar letter boxes and letter bags.* Dated March 3, 1862.

This consists in so constructing bags for the inside of pillar letter-posts that, on the carrier opening the door to take the letters, the bag instantly drops and becomes locked by the springing together and closing of the frame of the bag. *Patent completed.*

580. J. B. A. QUIQUANDON. *Improvements in jacquard machines, and in the pattern cards to be employed herein.* Dated March 3, 1862.

This relates to an improved mode or method of working the pattern cards in jacquard machines, and to a peculiar construction of pattern card, which improved card the inventor calls the "composteur quiquandon," and by the use of which one set of cards may be made to serve for any number of different designs, by suitably adjusting or modifying the same to suit the particular design or pattern to be produced. According to this invention, the series of pattern cards, in lieu of being connected together in the form of an endless well or chain, as heretofore, and, consequently, occupying a considerable amount of unnecessary space, are used separate and detached from each other, one card being placed immediately behind another, in a suitable support or holder in front of the needles. The front card, after having acted upon the ends of the needles, is made to descend, and is deposited by a traversing carriage, or other convenient arrangement of self-acting mechanism, in the rear of the other cards, whilst the second card comes into operation, and is in its turn lowered and placed behind the first, and so on throughout the series. *Patent completed.*

581. G. BISCHOF. *Improvements in treating ores and solutions containing copper and iron, or either of them, to obtain products therefrom.* Dated March 3, 1862.

To the solution to be treated the inventor adds chloride of calcium, or other chloride of an alkaline earth, or of an alkali, which is capable of separating the sulphuric acid from sulphate of copper and sulphate of iron. It will probably, however, in almost every case, be most convenient to use chloride of calcium. In this way he obtains in solution chloride of copper and chloride of iron, or one of these, and a sulphate of an alkaline earth, or alkali, either soluble or otherwise, which is separated. This being done he adds to the solution of metallic chloride, lime, magnesia, or baryta. Lime, or a mixture of lime and magnesia, will, however, be most useful. In this way he obtains a precipitate of oxide of copper and oxide of iron, or one of these. Mixed oxide so obtained may be readily smelted to obtain metallic copper; oxide of copper, if obtained separately, may be similarly treated, or otherwise used as oxide of copper. Oxide of iron, if obtained separately, may be applied to any use to which other precipitated oxide of iron is applicable. *Patent abandoned.*

582. W. CONISBEE. *Improvements in colour-printing machines for letter-press or block printing.* Dated March 13, 1862.

This invention is not described apart from the drawings. *Patent completed.*

583. H. BUNNING. *Improvements in the manufacture of lubricating or compounds.* Dated March 3, 1862.

This consists in combining one or more of those natural mineral oils or matters known as American petroleum, also as rock oil, Cuba rock oil, and rangoon oil, or earth, with vegetable oils or grease, or with both, and with an alkaline solution. *Patent completed.*

584. F. B. HOUGHTON. *Improvements in the manufacture of paper.* Dated March 3, 1862.

This consists in boiling the chaff (which the patentee prefers to be cut longer than heretofore—say from an inch to an inch and a-half) to an extent sufficient to reduce the more fibrous parts to a pulp, having the knots and weeds as little disintegrated as may be, and then, having washed out the alkali, a coarse "knotter" is used, which will allow the disintegrated vegetable matter to pass, whilst the extraneous matters will be arrested. The pulp so obtained will retain its fullest strength and weight, and require the minimum of bleaching material to act upon it. The "knotter" he prefers consists of a plate with square or oblong holes, sufficiently small to impede the passage of the knots and weeds. *Patent completed.*

585. J. GJERS. *A material or sand for the formation of moulds for casting iron and for other like purposes.* Dated March 4, 1862.

The patentee claims the use of furnace slag reduced to the required state of fineness or division (either alone or mixed with natural sand) in the formation of moulds for casting iron or other metals. *Patent completed.*

586. J. ELLIS. *Fastening chains, or any other thing to which it can be attached, and of any dimensions.* Dated March 4, 1862.

This guard is formed to resemble a common chain swivel of any size, but arranged so as to be detached and united by means which cannot accidentally occur. The link resembling that in a common chain swivel, is cut so close to the stem, which works and revolves in the cap, as to barely leave space for the cut point to slide along a rifle groove, first on the outside, and afterwards along the inside of a groove in the cap. A screw ferrule works on the end of the hook and the stem, so as to form a complete link when screwed up close. The head of the hook at the end of the stem, when raised above the cap in order to detach it, comes into contact with the link or fastening to which the cap is suspended. A groove in the head of the hook allows it to pass, so that it may be completely reversed. The point of the hook has then to be guided along the inner groove of the cap, and the hook is thus freed or separated from the swivel cap. *Patent abandoned.*

587. B. STANDEN. *Improvements in the preparation or manufacture of portable manure or fertilizing compound, and in the collection or extraction therefrom of a certain liquid applicable to various purposes, and also in machinery or apparatus to be employed therein.* Dated March 4, 1862.

The aparatus employed for carrying out this invention cannot be described apart from the drawings. *Patent completed.*

588. PHILIPP SCHAFFER and FREDERICK SCHAFFER. *Improvement in travelling bags, portmanteaus, and other similar bags and cases.* Dated March 4, 1862.

The object of the present invention is to prevent access to the contents of the bags, portmanteaus, and other cases by cutting, and the patentees effect this by inserting between the outer leather or other like material, and the lining, metal cloth or wire gauze, or they form the lining itself of such cloth or gauze. They prefer to employ that metal cloth composed of split steel rings. *Patent completed.*

589. COLONEL SMITH. *Improved sight of fire-arms, applicable also as an apparatus for measuring angles.* Dated March 4, 1862.

This sight or apparatus is composed of a tube in which two prisms of equal refractory power, independent of each other, are fitted in such manner that they may be made to revolve through equal angles in opposite directions. *Patent abandoned.*

590. W. TONGUE. *Improvements in machinery for breading, rubbing, and scutching, flax, hemp, or other vegetable fibrous materials, and in processes for treating silk waste.* Dated March 4, 1862.

We cannot here quote the voluminous details of this invention. *Patent completed.*

591. A. J. SEDLEY. *Improvements in metallic bedsteads, sofa bedsteads, and folding chairs or seats.* Dated March 4, 1862.

Here, when constructing a metallic bedstead, the head and foot frames are hinged or connected to the side rails of the bottom frame of the bedstead in the following manner:—The ends of the side rails of the bottom frame are bevelled or inclined, and within a few inches from each end of these side rails one end of a link is attached by a pin joint, the other end of such link being attached also by a pin joint to the lower end of the side rail of the head or foot frame of the bedstead, and the lower end of this rail is also formed to a bevel corresponding to that of the end of the side rail of the bottom frame of the bedstead; so that, when the head and foot frames are set up, the inclined end of each of the side rails of the head and foot frames butts against the inclined end of its side rail, and the links which connect the head and foot frames to the side rails are then horizontal, or nearly so. To fold down the head and foot frames, it is simply required that such head and foot frames should be lifted, when the links will allow of the folding. *Patent completed.*

592. G. A. COTTAM and H. R. COTTAM. *Improvements in horticultural buildings and other glazed structures.* Dated March 4, 1862.

Here the metal rafters, or the sashes or parts to be glazed, are formed with a succession of steps, according to the number of sheets of glass to be used from the top to the bottom; and it is preferred that these steps should be in the forms of groves, so that the succeeding sheets of glass may be slid into their places and overlap at their edges, though a single groove may be used of sufficient depth to receive the thickness of glass one over the other. When walls are used in constructing a building, the rafters are connected therewith by metal plates, in the form of inverted troughs, either extending the whole length of the building, or else at such intervals apart as will suit the distance apart at which the rafters are desired to be attached to the wall. Where required, tie or guage rods or bars are applied, to retain the rafters in position. When using wrought iron sash bars, in order to connect them to the structure or to each other, cast iron sockets are used, which are fixed to the ends or other parts of the sash bars by pins or rivets, or otherwise; and when required such cast sockets are made with branch sockets at a right angle, or such other angle as may suit the angular direction in which it is desired to fix the ends of other sash bars to the primary one to which the socket is fixed. At the surface of the ground, where necessary, a sill or bar is fixed or applied in any convenient way, but it is preferred to use a row of wood posts or stakes, driven into the ground, the parts so driven being well charred. *Patent completed.*

593. T. GREENWOOD. *Improvements in sewing machines.* Dated March 4, 1862.

This relates to an improved form of driver for propelling the shuttle in platform sewing machines, whereby the shuttle is more securely held, and the liability to miss the loop is reduced. In the extremity of the vibrating arm, which communicates motion to the shuttle, a socket is made to receive a pin, which is jointed to and projects laterally from the shuttle driver. By this means, therefore, the vibrating arm and shuttle driver are connected together by a kind of loose musical joint. The driver is formed with two projections, which serve to embrace the shuttle. One of these projections is forked, and embraces the nose of the shuttle, and the other bears against the rear end thereof; and the shuttle, although effectually secured by the driver, will move freely backward and forward in its race. The invention also relates to the arrangement for regulating the presser foot over the feet wheel to suit the work under operation. Instead of attaching to a fixed point the tension spring, which gives the downward pressure to the presser foot on the face of the guide box, in which the vertical needle stem and presser foot stem works, a lever arm is mounted for holding one end of the tension spring. Bearing upon the outer end of this arm is a regulating screw, which is tapped into a lug attached to the guide box. By turning, therefore, this regulating screw the lever arm may be readily caused to increase or diminish the tension of the spring, and thereby put any required pressure upon the presser foot. *Patent abandoned.*

594. G. F. GUY. *Improvements in electro-magnetic motive-power engines.* Dated March 4, 1862.

This relates to a peculiar construction, arrangement, and combination of apparatus for obtaining motive power, by the aid of electro-magnetism, and consists in the use of one or more series of electro magnets arranged in circles, and made to act successively upon a ring of soft iron, which is made to roll over their faces or poles. This ring is connected to the main shaft of the machine by any convenient arrangement of universal joint which permits of its gyrating in all directing in all directions round the shaft, whilst it is at the same time coupled thereto, so as to be incapable of rotating without carrying the shaft round with it. *Patent completed.*

595. J. SIDEBOTTOM. *Improvements in fire-arms and ordnance, and in projectiles.* Dated March 5, 1862.

This consists in an improved mode of constructing the breaks by which the recoil of the barrel is regulated or controlled, as described in the Specification of Letters Patent, granted to the present patentee on the 24th of July, 1861 (No. 1853). According to the present improvement, he makes the break in the form of a wedge, and he applies it in the bearing by which the barrel of the fire-arm or piece ordnance is supported. The improvements in projectiles are applicable to smooth-bored and rifled fire-arms and ordnance, and they consist in making the rear end of the projectiles conical; the front end of the projectile is rather less in diameter than the bore of the barrel, so that it may easily be introduced, either from the muzzle or at the breach. On the conical end of the projectile an annular ring of iron or other metal or material is placed; this ring is either solid, or provided with one or more diagonal grooves, slats, or perforations. When the powder explodes the annular ring is forced up the conical end of the projectile, and in so doing its outer circumference is expanded until it accurately fits the bore of the barrel and the rifle grooves (when the barrel is rifled), thereby preventing windage, and imparting the full force of the powder to the projectile. In some cases the exterior of the annular ring may be made to fit the rifle grooves of the barrel. Another part of the invention consists in constructing projectiles of a series of discs of cast iron or other metal, which discs are held together by a central bolt. These projectiles answer the purpure of grape shot. *Patent completed.*

596. W. TONGUE. *Improvements in machinery for preparing silk, flax, hemp, or other fibrous materials.* Dated March 5, 1862.

This refers to a previous patent, dated 27th Jan., 1859 (No. 249), in which the fibrous material, in its passage from a pair of feed rollers, or screw gill feed apparatus, to a pair of delivering rollers, is operated upon by the teeth of a comb having a reciprocating motion given to it in the direction of the length of the sliver of fibrous material. The first improvement consists in so arranging the moveable or reciprocating comb, as to cause the teeth to be mounted or to pass downwards through spaces or openings in a plate or frame into the sliver of fibrous material, a brush or other instrument being employed to support the sliver when the teeth of the comb are withdrawn. The invention also consists in giving an intermittent movement to the delivery rollers, so that they may be at rest, or nearly so, whilst the teeth of the reciprocating comb are withdrawn from the sliver, and whilst the comb moves backwards to enter the sliver. Another improvement consists in causing a series of points to enter the sliver, and arranged in combination with the brush or other depositing instrument, in order to hold the fibres and prevent the derangement thereof during the backward movement of the reciprocating comb or combs. There are various other features included. *Patent completed.*

597. J. SOMERVELL, R. M. SOMERVELL, and M. BLANC. *Certain improvements in the manufacture of boots and shoes.* Dated March 5, 1862.

This consists in the manufacture of boots and shoes with soles of walnut, or other suitable wood, an angular groove being cut in the edge of the sole, to which the upper is attached by strong wire nails, or otherwise strong wire staples U-shaped. A piece of leather is then sprigged on to the sole and heel of the boot, or shoe, so as to cover them, and this leather is protected by hobs or other strong nails, tips, or plates. Also in the formation of an imitation welt, by which the heads of the wire nails are entirely hidden. This is accomplished by inserting the nails a short distance from the edge of the upper; the margin of leather thus left is then worked up, and afterwards set. Also in a shaped iron plate, which is screwed on to the waist of the sole in some cases, so as to add to its strength. *Patent completed.*

598. W. KENSMAN and W. KENSMAN, JUN. *Improvements in apparatus for tilling land by steam power.* Dated March 5, 1862.

This consists of a frame or carriage mounted on six wheels—two land and four furrow wheels. To the plough beams, shares and coulters are affixed in pairs on the opposite side, of the beams, which are capable of being lifted and reversed at the end of each course. At the side of the plough there is a sliding rod, connected by chains to draw links, to lay the drag rope in its proper place ready for the return course. The plough beam and coulter have a plain or indented bead, and the coulters are secured to the plough beam by improved adjustable clamps. The improvements in apparatus for transmitting power from the steam engine to the plough consists in a novel mode of lifting the pinions out of gear with the rope drums, and checking the revolutions thereof by a simple lever. *Patent completed.*

599. J. CHUBB and H. M. BURTON. *Improvements in apparatus for displaying or exhibiting jewellery and other valuable articles in glass cases.* Dated March 5, 1862.

Here apparatus is applied below the table, or surface on which the articles are placed, in such manner that the articles may at any time be enclosed in an iron or other suitable metal safes. *Patent completed.*

PROVISIONAL PROTECTIONS.

Dated April 30, 1862.

1278. A. Prince, 4, Trafalgar Square, Charing Cross. A new composition for casting to represent marble. (A communication.)

Dated July 21, 1862.

2074. A. Naudain, West Farms, West Chester, New York; J. Peacock, Morrisania, West Chester, New York; and W. H. Walton, New York. Improvements in looms for weaving all kinds of textile fabrics.

Dated July 31, 1862.

2176. W. E. Newton, 66, Chancery Lane, civil engineer. Improvements in lubricating compounds. (A communication.)

Dated August 12, 1862.

2252. J. Ramsbottom and G. Hacking, Accrington, Machinists. Improvements in machinery or apparatus for measuring and registering the flow of water and other fluids.

Dated August 13, 1862.

2269. J. R. and F. C. Tussaud, Marylebone Road. Improvements in the treatment of representations formed from wax, or from compositions of wax with other matters.

Dated August 14, 1862.

2286. G. White, Torquay, plumber; F. Buckland, Newton Abbott, auctioneer; and C. Rees, Newton Bushel, accountant. Improvements in the manufacture of water-closets.

Dated August 15, 1862.

2300. A. Shepard, 55, Victoria Street, Westminster. Improvements in obtaining light and in apparatus connected therewith.

2304. J. Carter, power loom regulator, and J. Maher, manager, Victoria Mills, Lockwood, near Huddersfield. An improvement in the construction of power looms.

Dated August 25, 1862.

2361. M. J. Haines, 4, Victoria Road Rope Walk, Bristol. Improvements in the manufacture of driving bands or straps.

Dated August 26, 1862.

2366. T. Richardson, Newcastle-upon-Tyne, Chemist, and R. Allison, accountant, Moorgate Street, City. Improvements in the manufacture or treatment of articles of steel, and in the apparatus employed therein.

Dated August 28, 1862.

2388. G. Biddle, Birmingham, brush maker. Improvement or improvements in the manufacture of brooms.

2390. E. Lachenal, Little James Street, Bedford Row. Improvements in gas meters. (A communication).

2392. G. Cooke, Mornington Crescent, Hampstead Road. Improved apparatus for securing or fastening doors to prevent robbery or intrusion.

Dated August 29, 1862.

2394. P. L. Guilbaud and N. V. Thiré, Paris, 60, Boulevart de Strasbourg, Practical Engineers. An improved self-inking hand stamp.

2396. F. H. Lefranc, Paris, Gentleman. Improvements in the manufacture of casks.

2398. J. Davis, Liverpool, Merchant. Improvements in the manufacture of spoons, forks, and similar articles. (A communication.)

2400. G. W. Dyson, Tinsley, York, Forge and Mill Manager. Improvements in machinery for finishing and polishing circular metal rods, bars, and shafts, applicable also to the manufacture of metal tubes and pipes.

2404. W. Upfill and W. Morton, Birmingham, Iron Merchants and Manufacturers, and W. Asbury, Engineer. Improvements in the construction of wheels and axletrees for carriages.

Dated August 30, 1862.

2406. E. T. Hughes, 123, Chancery-lane. Improvements in the manufacture of woven fabrics, and in apparatus employed therein. (A communication.)

2408. F. Le Conte, No. 10, Rue des Tarisses, Tournay, Belgium. Improvements in the construction of furnaces for steam boilers used in sugar mills, distilleries, breweries, and other mills or factories.

Dated September 1, 1862.

2414. J. Walker, Glasgow, manufacturing chemist. Improvements in the treatment of kelp, and in the manufacture of products therefrom.

2416. J. Ellis, Old Market Street, Bristol, staymanufacturer. Improvements in corsets.

Dated September 2, 1862.

2424. D. B. Peebles, Edinburgh, engineer. Improvements in wet gas meters.

2426. W. Hunt, Tipton, manufacturing chemist. Improvement or improvements in the manufacture of muriate of ammonia.

2428. R. Glanville, Bermondsey, Engineer. Certain improvements in marine and other engines.

2430. W. Roberts, Millwall. Improvements in apparatus for regulating the amount of water discharged by a pump, chiefly applicable for regulating the amount of water thrown by a steam fire-engine, or for regulating the amount of water fed to a steam boiler.

Dated September 3, 1862.

2434. C. Garton, Bristol, brewer. An improved method o applying heat in the manufacture and refining of sugar and in malting, hop drying, brewing, distilling, and vinegar making.

2438. W. H. Atkinson, Cavendish Club, Regent-street, gentleman. Improvements in studs or fastenings adapted to holding together parts of shirt fronts, wrist-bands, collars, gloves, and other articles of wearing apparel.

2440. E. Dyson, Little Hulton, near Bolton, cotton spinner. Improvements in throstle spinning and doubling machines.

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

1278. A. Pnirce. Composition for casting. (A communication.)

1312. T. Snowdon. Manufacture of steel tyres, hoops, and cylinders. (A communication.)

1313. J. M. Heppel. Permanent way.

1314. E. Herdman, A. F. Herdman, and J. Herdman. Manufacture of wrought iron and steel.

1332. C. Binks. Obtaining hydrogen gas and certain gaseous compounds of hydrogen and carbon.

1341. J. Adcock. Measuring and indicating distances.

1345. A. Morel. Heckling machines.

1355. J. E. Ransome, W. Copping, and L. Lansdell. Harrows.

1358. E. Bourdon. Construction of blowing fans.

1359. C. V. de Berville. Safety coupling bar.

1362. T. H. Hopwood. Raising sunken vessels.

1365. J. Johnson and A. Chapman. Preventing collisions.

1372. D. Marchal and A. C. de Wiart. Preventing the destructive effects of vibration or jar on the permanent way of railways, and on the wheels, axle-trees, and other parts of carriages, and the working and other parts of machinery liable to shocks.

1385. L. D. La Peyrouse. Treating neutral and acid, fatty or oily substances, resins, and resinous substances.

1387. G. F. Greiner and J. H. C. Sandilands. Construction of pianofortes.

1389. L. D'Aubreville. Metallic cross-sleepers for railways.

1390. T. K. Mace. Guards or protectors for hats.

1394. T. Fawcett, jun. Plaited fabrics.

1403. W. Clark. Manufacture of felted and other fabrics.

1404. R. Moore. Indicating the presence, position, or accumulation of liquids, gases, and vapours.

1409. J. House. Machinery for crushing or reducing substances.

1412. J. B. Cristofini. Tents.

1415. H. Walker. Handles for crochet-needles, pencils, penholders, and other articles.

1416. J. Milnes. Exercising the human body.

1417. G. Fuhrmann. Melting and boring cast steel barrels.

1424. H. Cartwright. Propelling and steering screw steam vessels.

1425. W. N. Hutchinson. Screw-propelled ships.

1427. H. Ashworth. Opening and carding fibrous substances.

1429. A. B. Freeland. Preparation or treatment of hops.

1431. T. Buckney. Portable "tell-tale" timekeepers.

1432. S. B. Ardrey and S. Beckett. Manufacturing spindles.

1441. R. A. Boyd. Manufacture of bacon.

1443. W. Clark. Generating motion in fluids. (A communication.)

1453. R. A. Brooman. Production of photographic and stereoscopic portraits and pictures.

1461. A. Nicole. Stop watches and time-keepers, and instruments for measuring accurately short intervals of time.

1482. R. Laming. Constructing and using electric telegraphs.

1492. F. Stocken. Carriages.

1494. A. V. Newton. Cutting leather. (A communication.)

1495. A. V. Newton. Cutting boot and shoe soles. (A communication.)

1517. A. V. Newton. Splitting leather. (A communication.)

1519. M. A. F. Mennons. Applying screw power to the locomotion of railway trains on steep inclines. (A communication.)

1576. G. A. Huddart. Superheating steam.

1594. G. H. Daw. Fire-arms.

1624. F. Datichy and E. Sabatier. Making pulp.

1722. A. J. Joyce. Lighting and heating.

1827. B. Fabbricotti. Polishing and grinding belt. (A communication.)

1894. M. A. F. Mennons. Prevention and reduction of synovial and other swellings or tumours in the limbs of horses.

1971. J. M. Gille. Calendar inkstand.

2006. M. A. F. Mennons. Floating batteries. (A communication.)

2077. T. Meriton. Steam engine governors.

2145. Z. Colburn. Steam pumping engines.

2241. T. Holdsworth and J. Crossley. Warping, scouring, sizing, stretching, measuring, cooling, drying, and beaming yarns for weaving.

2331. J. Standish and J. Gooden. Preparation of cotton, wool, flax, or other fibrous materials to be spun.

The full titles of the patents in the above list can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list who have given notice of their intention to proceed, within twenty-one days from the date of the *Gazette* in which the notice appears, by leaving at the Commissioners' office particulars in writing of the objection to the application.

LIST OF SEALED PATENTS.

Dated April 29, 1862.

683. J. and R. Cunningham.
684. J. Hunter.
687. J. Wadsworth.
692. R. A. Brooman.

NOTE.—Specifications will be forwarded by post from the Great Seal Patent Office (publishing department) on receipt of the amount of price and postage. Sums exceeding 5s. must be remitted by Post Office Order, made payable at the Post Office, High Holborn, to Mr. Bennet Woodcroft, Great Seal Patent Office.

The contractors of the Rome-Naples Railway have been very urgent in recommending the Vatican to bring these two cities within eight hours of each other, but their appeals have not been reciprocated.

The tombstone that covered at Longwood the grave of Napoleon I., together with the rusty iron railing that enclosed it, were left at Cherbourg in 1840, when Prince de Joinville landed the coffin out of the "Belle Poule." These memorials are now to be also forwarded for exhibition at Paris, and are to figure in that wing of the Louvre where the saddle, camp bed, writing desk, &c., of the first Bonaparte may be seen.

We have to announce the demise on Monday last of Mr. Charles Pearson, who for many years was the solicitor to the Corporation of the City of London, and the original promoter of the great scheme of the Metropolitan Underground Railway.

CLOSING FRUIT JARS.—For the preservation of all kinds of fruits, use glass bottles or jars. Select those of even thickness, or rather of even thinness, for they are often exposed to considerable heat, and while they should not be so thin as to break in common handling, or burst from internal pressure caused by fermentation, still they should not be thick, or of pressed glass, when blown-glass jars can be readily obtained. So much for the bottles. Now, as to closing them air-tight, we know corks will not do it. The very substance of the structure is against it, unless cork of the most velvety character is obtained, and this is costly. We recommend waxed cloth tied over the jar, as a substitute at once cheap and effective, and have never found anything superior to it. Prepare the cloth in this way:—Melt together some resin, beeswax, and tallow in equal parts; tear the cloth in stripes four inches wide, or, at least, wide enough conveniently to tie over the mouth of the jar, and dip these strips, drawing them through the hot wax and stripping nearly all the wax off. With cloth thus prepared, after the jar is filled with hot preserves, and while still hot, close the mouth and bind it on with good linen cord. Then, with shears, trim off as much of the waxed cloth as is desirable, and then dip it in some melted wax, which should be made with only about half as much tallow. Sealing-wax may be used instead if desired. The jars should be put where the wax will cool at once, so that the exhaustion caused by the cooling of the preserves and the condensation of the steam, may not cause the wax to run through the cloth. Nothing can be more thoroughly air-tight than bottles so prepared.—*Homestead.*

THE
MECHANICS' MAGAZINE.

LONDON, FRIDAY, SEPTEMBER 26, 1862.

OUR WEEKLY SUMMARY.

WHAT with Horfall guns, Whitworth projectiles, and destructive infernal machines, our iron-cased vessels made and making cannot be said to be invulnerable. The Americans have hitherto been principally famed for constructing infernal machines, but, if report speak truly, a Finlander in the Russian service has invented the best machine of the kind. The apparatus is said to be extremely simple, and to cost but little in construction. It consists of a glass reservoir, which, when filled with powder, will float at a certain depth, and when brought into contact with a ship's bottom will produce disastrous results. Experiments have recently been made with this machine in the royal dockyard at Nyholm. The first experiment shattered the framework of the gunboat, and sent some of its planks to a height of 80 or 100 feet. The second experiment threw up a column of water 100 feet high, and the shock was felt for a considerable distance. We give currency to this report with considerable reserve, as it may have been put in motion by the inventor himself. Inventors, when describing their plans, make their own ducks swans.

The accident at Malvern-hill railway tunnel appears to reflect on the engineering capacity of Mr. Liddell, engineer to the Worcester and Hereford Railway. A correspondent informs us that the principal portion of the tunnel has been bored through hard cyanite rock. On the Worcestershire side there was constructed an air-shaft about 100 yards in the tunnel. This shaft, which was built of brick, rested on the arch of the tunnel, which gave way, carrying the whole of the shaft with it. Luckily, indications of the coming disaster were seen in time for the workmen to get out of the way, and no lives were lost.

The bread-making-by-machinery controversy still continues in a morning contemporary; and, as far as we can judge from the many letters which have been published, Stevens' machine is condemned by most practical bakers. The inventor of that machine gets severely criticised for the manner in which he has caricatured the universal baking trade. Many a baker has stepped forth to vindicate his own establishment and others with which he is acquainted. One correspondent, who had tried Stevens' machine, and Vicars & Co.'s. mixer, speaks highly of the latter. He thinks the only effectual way to give the public pure bread, is for the bread to be manufactured in large quantities by public companies or large capitalists, employing the best machinery, in large, open, and healthy workshops. Then, and not till then, he says, will the baking trade be brought on a level with other manufactures, and the public have a chance of receiving that which they have a right to expect—namely, pure bread. Another correspondent, Edwin Clayton, of Nottingham, gives an account of a bread-making machine which he patented in the first year of William the IV. The machine consisted of a rotary barrel and revolving knives, the motion or action of each being quite independent of each other. The entire materials of the batch of bread are placed within, the lid closed, and the machine worked by two men; and in ten minutes fifty stones of dough may be made ready to lighten, without being touched by hand or seen by eye. A machine made on this principal has been used in Southwell House of Correction for nearly thirty years. The inventor says "that a two-sack machine made on his principle will cost about twelve pounds; and, as "the patent right has long since expired, any-"body may use it." What becomes of the patent rights of the bread-making machines which have adopted this principle of rotary barrel and revolving knives? What becomes of Mr. Steven's patent rights? This controversy on bread-making is an important and interesting one, and we shall return to it.

The wreck register shows a fearful increase of casualities on the British coast for the year 1861. The statistics of the Board of Trade give 1,494 shipwrecks during that year, being a considerable increase upon the number during any of the preceeding nine years, and 260 above the annual average of the last six years. The estimated loss of property on these 1,494 wrecks is upwards of one million; the more serious loss of human life was 884 persons. The question is pertinent—could any precaution have lessened the number of these casualties? The well tabulated returns of the Board of Trade do more than suggest that many of them were preventable. We have applied ourselves, not unsuccessfully, in lengthening the tenure of human life on land, by diminishing those contingencies which increase our bills of mortality. We may not avert the storm or the gale, "man's control stops with the shore," but by proper precaution in providing for danger and wrestling with it when it comes, we may confine disaster and death within the narrowest limits which human efforts can impose upon them. We find that 10 wrecks took place in a perfectly still sea, 14 in light airs, 51 in light breezes, 43 in gentle breezes, 103 in moderate breezes, 171 in fresh breezes, 149 in strong breezes, 66 in moderate gales, 124 in fresh gales, 230 in strong gales, 311 in whole gales, 102 in storms, 52 in hurricanes, and 68 in unknown and variable weather. Of these 619 took place amongst ships in the home and coasting trade, commanded by men not required by law to have certificates of competency; 266 wrecks only occurred amongst vessels commanded by masters holding certificates of service. In all, there were 842 wrecks amongst our rotten collier class of vessels. Again, with regard to collisions, it appears that, during the last six years, 750 have taken place in clear and fine weather, 378 from bad look-out, 264 from neglect of rule of road at sea, and 61 from actual want of seamanship. So, then, unseaworthy ships, incompetent masters, and another cause or two—which we may not hint at, but with which "Lloyds" is not altogether unacquainted—have led to the destruction of many lives and much property, and swelled the list of casualties on our coasts for the year 1861. With causes so well defined, is not the remedy obvious?

It is quite natural that the great cotton question should continue to occupy a considerable amount of public attention. During the week the annual meeting of the Cotton Supply Association has been held at Manchester, and we are sorry to see that the report and the speakers took a rather desponding view of the matter. We have been induced to look at India as the principal field from which we might obtain cotton supplies. But what good are a productive soil and industrious lands if the means of transport be wanting. Mr. Haywood, who was sent to India by this association, says that no doubt India is capable of supplying from 4,000,000 to 5,000,000 bales of cotton annually; and that, had land and water communications been more extensively opened throughout the country, our present imports from thence would by this time have been doubled; that the rapid completion of railway will prove of enormous advantage, by hastening the establishment of European agencies in the interior; that branch feeders, whether railways or roads, will be required to connect the main lines with the remoter districts; and that more bridges are required, the construction of which would save thousands of miles of circuitous traffic. In fact, India wants the civil engineer and capitalist more than the cotton cultivator. The capacity is there to supply our wants, but the means of bringing the produced article must also be supplied. In this important crisis of our national history we are sorry to find that the government has not done more to promote productive works in India. Much blame is deservedly fixed on Sir Charles Wood, for his wooden-headed resistance to all improvement. In fact, the Manchester meeting called for his dismissal in most unmistakable language. That he is an incompetent minister there can be no doubt, and that he occupies his present position, not from any merits of his own, but by virtue of family influence, is equally well known.

It is not at all an unlikely thing that Turkey will by-and-bye be enabled to send us at least 100,000 bales of cotton annually. But Turkey, like India, wants English engineering skill, capital, and experience. The Turkish government is even showing more interest in the matter than the English government. In the International Exhibition there are contributions from thirty-five sources of cotton supply, yet the country had essentially depended on one of them. Should peace be established in America to-morrow, the Southern states would not be able for years to come to send us the accustomed supply. It therefore becomes a question of national necessity to get large quantities of the article supplied from other quarters.

In our last number we drew attention to the various substitutes proposed for cotton, during the past few weeks. Since then, however, another important step has been taken, which raises our anticipations to a higher pitch, and causes us to hope that the substitution of sea-weed may not turn out a disappointment. If, indeed, this should occur, there will be nothing to regret in the actions of the discoverer, who has manifested throughout singular disinterestedness.

The discoverer of the new fibre, Mr. Henry Harben, of Oxford-villa, Haverstock-hill, while spending a holiday at Harwich, tried various experiments upon sea-weed, and then upon *Eostera Marina*, which is known as common grass-wrack, growing in abundance on the sea shore. Though not a sea weed, it grows among them; the leaves, resembling a long narrow tape, often reach from three to four feet. It is found from the North Sea to the Mediterranean, in the Indian Ocean, and on the Arabian coast. It is not unknown to the country, having been used for a long time for stuffing cottagers' cushions and beds, and has also been introduced into the paper-makers' vat. Mr. Harben, at the committee meeting at the Manchester Chamber of Commerce, exhibited several specimens of the fibre in its natural state, and as used as paper, and as dyed, and dried. So sanguine was he of the results of any experiments that might be made upon this elastic, and it is said silky, texture, that he advised the unemployed operatives at once to collect it from all the sandy coasts of the country.

Whatever may be the feeling relative to this

discovery, and the admiration in which the discoverer is now deservedly held for his disinterestedness, it is still a question to be solved whether, after all, this is a material that can be converted into a substitute for cotton. There are many things to be said in its favour; and yet there are certain considerations which await solution, upon which the worth of the discovery depends. It must be ascertained whether it grows in such quantities as may be required, and then whether the fibre is capable of being spun on the machinery used for cotton; and, lastly, the essential consideration must be determined whether it will be as cheap as cotton. Specimens have been exhibited during the week, and favourable opinions have almost universally been expressed, so that it is not really a question whether it is likely to be in the abstract successful. That it can be turned into a substance which may be used as cotton, has, we think, been almost universally acknowledged; but the questions we have submitted for solution are important ones, and bear materially upon the acceptance of this new material.

It may turn out, however, that Mr. Harben was not the first to discover the capabilities of sea-weed as a substitute for cotton. A Mr. C. M. Archer in a letter states:—" Permit me to state that so long since as November, 1855—a period when there was a panic concerning an apprehended scarcity of fibrous material for paper—I then, residing at Haver stock-hill, after the usual labour, experiment, and expense, received professional protection and specification, No. 2,696, November, 29, 1855, from the Commissioners of Patents, for the 'production of fibre and paper pulp from sea-weed, and for the production of textile fabrics from the same.' I could descant on the question if required, but will be content if you will allow this fact, in fairness, to appear in the same columns that gave Mr. Harben's 'discovery' to the world; consoling myself with the old saying 'Sic vos non vobis."

THE IRON MANUFACTURE OF GREAT BRITAIN.

It has seldom fallen to our lot to introduce to the notice of the scientific public a more valuable work than that of which the title will be found at the foot of this page of the Mechanics' Magazine.* It is evidently the result of long, careful, and practical observation; and it forms at once a glorious monument to the memory of its author, and an excellent guide to those who are directly or indirectly interested in the great subject of which it treats. In the preface to the first edition of "The Iron Manufacture of Great Britain," it was truly said that, "among the manufactures "of this country, that of iron has risen to a "magnitude which entitles it to rank as the "most important, both as regards the value "of the products, and the direct bearing they "have on the progress of civilizstion and "commerce." If this were true at the time it was written, most assuredly its truth comes home to us now with intensified force, for the development of the iron manufacture of Great Britain, during the past few years, has been marvellous; and at this moment that development, so far from exhibiting signs of abatement, is proceeding with increased spirit. It is needless to trace the momentous consequences which result to us, as a nation, from this ever-growing and persistently-energetic demonstration of material wealth and industrial talent. Those consequences are well known at home and widely felt abroad. The railroad, steamboat, the armed leviathans of the ocean, everything that mind can conceive or devise, and skill realize in the form of iron manufactures, are helping to maintain this country as the foremost among the nations of the earth; and, humanly speaking, there is small chance of our national declension, so long as superiority in the manipulation of iron is preserved to us.

The book which Mr. Truran has left us as a rich legacy, and which his moral and literary executors, Messrs. Phillips and Dorman, have taken great pains to place in the best and most available form before the scientific world, fills a void which, despite the efforts of many other able writers, existed in relation to the iron manufactures of Great Britain. It at once illustrates the progress which has heretofore been made in the wide and well cultivated fields of industry of which it takes cognizance, and indicates the directions in which present and future workers in that field must persevere if they would achieve yet further success.

The preliminary chapter of the work deals with various ores which are obtained in the iron districts; and with great minuteness describes their peculiarities, and individual characteristics. It is not, perhaps, needful for us to follow the author, and his *collaborators*, through this interesting and instructive department of their subject, although it must be admitted that it is fraught with importance, as metallurgists have not paid so much attention to it as they ought. Suffice it to say, that for the sake of facilitating explanation, the ores from which crude iron is omitted in Great Britain are divided into four great classes:—1st, the argellaceous ores of the wet formations, having clay, but sometimes silica, as their chief impurity; 2nd, the carbonaceous ores of the same formation distinguished by their large per-centage of carbon; 3rd, the calcareous ores, principally obtained from the limestone of the coal measures, and having lime as their chief earthy admixture; and 4th, the siliceous ores, having silica as their predominating earth. The last class is sub-divided into the red and brown hexmatites, the ores of the oolite formation, the white ex-carbonates, and the magnitu oxides. Careful descriptions follow of the circumstances under which the several ores referred to are usually found, and also tables, demonstrating the proportions in which the impurities named are generally enveloped on analysing the ores themselves. We are not aware of the existence of any more complete or practical exemplification of the nature of the iron ores of this country, than is afforded by the work under review; and we imagine, therefore, that to iron smelters this chapter will be of especial value. As a natural sequence to their account of this branch of iron manufacture, the author leads us to a consideration of the fuel and flux employed in the elimination of the crude iron from its natural companionship and native adulterations. "The fossil fuel with which this "country abounds is now almost exclusively "used in all the various operations connected "with the manufacture of iron. Charcoal is "now, from its high price and scarcity, only "used for the conversion of malleable iron into "plates and bars for tinning, and other pur-"poses where a very superior quality of iron "is desired. The South Wales basin is at "present that from which the largest quantity "of coal is being extracted and used in the "iron manufacture. Its great area, and the "superiority of its products over those ob-"tained from any other formation in this "country, will, doubtless, enable it to main-"tain this position for many centuries to come. "It possesses, indeed, coal of nearly every "quality with which we are acquained. On "the eastern side the seams are generally of a "bituminous character. Further west, fol-"lowing the northern outcrop, they are found "to be semi-bituminous, as at the Rhymney, "Dowlais, and Penydarran works; and in the "Neath Valley the different seams are changed "into anthracite; and the characteristic of the "Welsh coals, and which distinguish them "from all others, is the large amount of carbon "they contain. In smelting, as well as in "other operations of the manufacture of iron, "the useful effect of coals is in direct propor-"tion to their richness in carbon. The Welsh "coals used in the blast furnace ordinarily "yield from 80 to 92 per cent. of carbon."

Following this testimony to the efficiency of the coals of the Welsh seams, for the purposes of smelting, and we are given lucid tabular statements of the coals of the Scotch and other fields and their varying components. To the iron founder it is needless to expatiate upon the importance of the information thus conveyed, because he will be fully aware of the good or bad effects which invariably follow the use of good or bad coal. It was, he well knows, a point upon which the quality of his castings much depends; and, next to obtaining irons suited to the particular work he has to produce, is the employment of the right fuel for melting them. It has been too much the practice of those who have the working of iron foundries to depend rather upon their own limited knowledge, or rather their own practical observation and experience, than to look round them for those general, but yet inevitable, laws which govern the operations of the furnace, and determine the quality of the castings which emanate from them. It is in the furnaces that this future casting has its character determined; and how consequential therefore is it, that the materials employed in the furnace should be so well understood, as to ensure good results. This work throws a strong and clear light upon the nature of the raw substances, from which good iron may be obtained, and upon the kinds of fuel, by aid of which, those substances may be made to yield the purest metal. It is of equal moment that in the foundry the rules which have been observed in the process of smelting should be followed because the best materials may there be spoilt by improper or careless treatment.

In the second section of "Iron Manufactures," the question of the calcination of ores is treated of, and the various kinds of kilns employed for the purpose are minutely described, and elaborately illustrated by plates. The importance of this operation is too well known to need any advocacy on our part. Calcination when properly performed, effectually deprives the ironstone of water, sulphur, carbonic acid, and other bodies capable of being volatilized at the temperature maintained in the kiln. The loss of weight resulting from calcination varies in amount with the character of the ironstone, and this loss is carefully tabulated in the book before us. "The rich hexmatites of Lancashire and Cumberland lose about six per cent. in weight by passing through the calcining kiln. The hydrated hexmatites of North Wales, Cornwall, Devonshire, and other places, on the contrary, are reduced in weight by the process, to the extent of 12 or 14 per cent., when clean. But if these ores be mixed with much extraneous matter, which

* The Iron Manufacture of Great Britain, theoretically and practically considered. Including descriptive details of the ores, fuels, and fluxes employed, the preliminary operation of calcination, the blast, refining, and puddling furnaces, engines and machinery, and the various processes in union, &c., &c. By W. Truran, C.E. Second edition, revised from the M.S. of the late Mr. Truran by J. Arthur Phillips, and Wm. H. Dorman, C.E. London: E. and F. N. Spon, 16, Bucklersbury. 1862.

unfortunately for iron-masters, is now too often the case, they are likely to lose 24 or 26 per cent."

We arrive now at another point, which has for some years past occupied largely the attention of practical men, but about which there is much yet to be learnt by many of them, and that is the proper construction of blast furnaces. Comprehensive particulars of the mode of forming those hitherto employed in the various districts in which they are used, and especially of those situated in Wales, are given, and practical suggestions towards improvement also abound. The cupola furnace is dwelt upon at some length, and the advantages resulting from their use demonstrated. Important alterations have been made of late in the apparatus employed for lifting materials to the level of the charging plates, where natural facilities for effecting the operation do not occur, and their alterations are carefully noted.

Without referring to the rather ancient means of accomplishing this object by the aid of water, it may be well to speak at some length of the pneumatic machinery, in several instances successfully used. The pneumatic lift consists of a well, sunk in the rear of the furnace, usually about 7 feet in diameter, and from 8 to 10 feet deeper than the height of lift. This is made water-tight by a brick, cement, or metal casing. A wrought-iron cylindrical tube, open at the lower end, and closed at the top, works up and down in this well. On the top of the tube a suitable platform is fixed, for carrying the loaded barrows. Four chains are attached to the platform, and passed over pulleys on the top of the frame-work, weights nearly sufficient to balance the tube and platform being hung to their extremities. Perpendicular timbers act as guides to the platform, which is furnished with four angular pulleys as guide rollers. A pipe, fitted with a stop valve, is brought from the blast main. This pipe is carried down one side of the wall to the bottom, then turned up in the centre, and brought to within four or five feet of the surface. The well is filled with water to within five or six feet of the top. The wrought-iron tube, open at the lower end, stands in it, and surrounds the central upright pipe. The action of the apparatus is as follows:—Loaded barrows having been wheeled on to the platform, the stop valve in the blast pipe is opened. The blast is thus made to press against the top of the tube with a force proportionate to its density, and to the area of the end of the tube. This force raises the platform, and thus carries the loaded barrows to a level with the charging plate. On arriving there, the blast valve is partially closed, and the tube is, *pro tem.*, sustained by the elasticity of the blast within.

The loaded barrows are now wheeled off, and after their contents are discharged into the furnace, they are replaced on the platform for descent. In order to accomplish this, the inlet valve below is closed by means of a vertical rod, and an escape valve at the top of the tube is opened, to allow of the gradual egress of the compressed air within. The pressure being removed from beneath the platform, naturally descends by force of its own gravity, and this with a spirit governed by the area of the escape valve.

By this admirable and economical arrangement it will be seen that the chances of accident are almost entirely obviated, whilst the workmen, by the use of the simplest possible apparatus, and without manual labour, are enabled to perform the duty of supplying the furnaces with the necessary charges. In ascending, the speed is easily regulated, the quantity of blast admitted being capable of adjustment to the exact requirements of the load to be raised. By partially closing the inlet valve before arriving at the top, the whole weight in motion, and which not unfrequently amounts to thirty tons, may be brought to a state of rest without concussion. It, in fact, floats, as it were, on a pillow of air to the exact height required.

At the Corbyn's Hall new furnaces we are told that "one pneumatic lift, with a tube of "five feet six inches in diameter, lifts the whole "of the materials for four blast furnaces. The "inlet pipe in this instance has a seven-inch "bore, the pressure of the blast being equal to "2⅓ lbs. on the square inch. The area of the "cylindrical tube in square inches, multiplied "by the pressure, that is 342 in. by 2⅓ lbs., "gives a lifting power of 7,981 lbs. The "load of materials lifted each time equals "5,040 lbs., and thus there remains a surplus "power of 2,941 lbs. to cover the unbalanced "weight of tube and all contingencies." The actual working cost of lifting the materials is as great, perhaps, as it would be with the inclined plane or water-balance lifts, but the cost of repairs is undoubtedly less. As, in our opinion, the principal of raising weights by pneumatic means, as well as the application of pneumatic force to other purposes, is likely to be carried much further than it has hitherto been, we have no hesitation in transferring to our pages the results of calculations made in the book, under the notices as to the expense of working the Corbyn's Hall lifting apparatus. The *cost* of accomplishing mechanical operations it need scarcely be said is one of the main considerations which govern their uses. "With an apparatus of the foregoing dimen-"sions, lifting vertically fity feet, the consump-"tion of blast is found to be about 1,200 "cubic feet for every one and a-half tons "raised. Allowing that it requires 8 tons "of material to each ton of pig-iron made, "an expenditure of 6,400 cubic feet, at a "pressure two and one-third pounds per "square inch, will manifestly be required to "raise the weight of materials named. The "cost of compressing air will be affected by "local circumstances (as for example the price "of coals); but at several of the Welsh works "it has been proved that the expenses of "compressing 100,000 cubic feet of air to the "density of two and one-third pounds on the "square inch, does not exceed 3d. This is "equal to three-sixteenths of a penny per ton; "and if to that be added another three-six-"teenths of a-penny, for the cost of erecting and "manufacturing the apparatus, we have a "charge of three-eighths of a penny per ton on "the pig iron made, as the cost of lifting the "materials 50 ft. high." To this statement it is not necessary to append remarks of our own, because it affords ample evidence of the expediency of adopting—wherever, as has been said, material means do not exist—pneumatic appliances for feeding the blast furnace.

The hot blast, now so extensively adopted in the manufacture of iron, is dwelt upon with satisfactory minuteness in the work before us, and to the general operations of the furnace many pages are devoted. This is followed by tables of analysis of the irons of the various seams of this country, as well as of other parts of the world. To these tables, which will add most materially to the knowledge already obtained by most of those persons to whom such knowledge is of value, it is not possible for us further to allude. This compilation demonstrates yet further the extraordinary amount of labour and research which has been exercised by those who have produced this remarkable contribution to the scientific literature of the country. The sixth section of the "Iron Manufacture of Great Britain" is devoted to the discussion of the vital questions of the "produce and quality of metal." As, however, our review has already extended to the full limit which can this week be afforded it, those questions, and the manner in which they are answered, must, perforce, stand over till the appearance of our next issue.

(To be continued.)

THE MANUFACTURE OF GUNPOWDER.*

So long as war continues to be the *ultima ratio* of nations, so long will it be important to pursue those investigations which have for their object the perfection of war *materiel*, whether for purposes of attack or defence. The book before us is an opportune contribution to the art and science of warfare. At a time when the merits of Whitworth and Armstrong guns, armour-clad vessels, &c., are exciting so much attention, and passing through the ordeal of severe scrutiny and unqualified discussion, such an elaborate work as Col. Anderson's becomes invested with more than ordinary interest. The body of the work was written by the late Colonel Anderson, and was intended by him to exhibit the result of his "earnest "study to acquire an insight into the theory "of gunpowder, and by much labour in mak-"ing numerous experiments to test and fortify "the art of manipulation as practised at the "Ishapore Mills." The MSS. were placed in the hands of Lieutenant-Colonel Parlby, who is an experienced artillery officer, and was for some years "agent for the manufactory of gun-"powder and war rockets at Allahabad, in Ben-"gal," and who has, by various notes and additions, sought to exhibit the progress of improvements to the present time. We join the gallant editor in his deprecation of the conduct of the authorities in refusing access to the reports of the experiments made at Woolwich and Shoeburyness at the national expense, and cordially agree with his observation that it would be "very useful if the causes of *the failure* in "every projected improvement were publicly "known and explained." *Failures* are great teachers; and the quotation by the editor of Watts' reply to one who was congratulating him on his extraordinary powers of invention and mechanical skill is very apposite,—"You "are regarding what I have succeeded in, but "you are little aware in how many instances "I have failed in perfecting what I aspired "to do."

In the first twenty pages of this volume we have a very succinct account of the "his-"tory of gunpowder." This account strengthens the generally received opinion that the manufacture of gunpowder originated in China and India, and that the absence of any written records indicating the precise date simply proves the antiquity of its discovery. This is the case with many substances. "Let us," says the editor, "con-"sider the subject of iron alone—the most "useful and widely-distributed metal on the "earth's surface. We know, from the earliest "and most sacred of writings, that the use of "iron may be traced back to the greatest an-"tiquity of the race of man, but all is perfectly "obscure as to the date of its first discovery, "except that it was most extensively used and

* Sketch of the Mode of Manufacturing Gunpowder at the Ishapore Mills, in Bengal, with a Record of the Experiments carried on to ascertain the value of charge, windage, vent and weight, &c., in mortars and muskets; also Reports on the various Proofs of Powder, by Colonel William Anderson, C.B., late Agent at Ishapore, with Notes and Additions by Lieutenant-Colonel Parlby, Retired Bengal Artillery. Weale. London. 1862.

"wonderfully worked up." That gunpowder and fire-arms were in use in India in the earliest ages the oft-quoted passage from Mr. Holhed's translation of the code of Gentoo laws, supposed to have been compiled at the time of Moses, B.C. 1500, sufficiently proves.—"The magistrate shall not make war with any "deceitful machine, or with poisoned weapons, "*or with cannon and guns, or any kind of fire-"arms.*" "The invaders of Northern India," says the editor, "may have brought these. "The repressive influence of the laws of the "Gentoo code, and their effect upon a super-"stitious, submissive, indolent, and uninven-"tive people, may have caused their use to lie "dormant for many centuries after their in-"vaders retired."

Speaking of the "early establishment of the "manufacture of gunpowder in Bengal," our author observes, that "the chief cause of the "inferiority in gunpowder is that, if the in-"gredients are not carefully refined, and care-"fully manipulated, the powder quickly de-"teriorates from its original strength of "propellent force when fresh from the mills. "In the early days of European occupation, "war and battle were too frequent to admit "of the powder being long stored in "the magazines. With native armies the "powder-makers followed the camp; the "women of families often manufactured the "article for the matchlocks of their husbands. "Such, too, at the present day, is the custom "in the wilds of Afghanistan, where the hand "flour-mills of the huts are occasionally seen "grinding the sulphur and saltpetre, to fabri-"cate a coarse powder for the use of the men "on their sporting occasions and plundering "forays."

Up to the year 1784, the Government was supplied, at a high price, from the native manufactories near Calcutta, where several existed. These were subsequently removed, as endangering the city, to Akra, where they continued some years. But this place, being considered too much exposed to the operations of an invading force, the celebrated miser, John Farquhar, who, it is said, speculated in every article of Indian produce, "from silk for the markets of Europe to *pork* for the bazaars of Calcutta," induced the Government in 1794, to exchange with Rajah Nubookessen some lands at Satanooly, near Calcutta, for the factory at Banku Bagnar, now called Ishapore, which he had re-taken from the Dutch. Here the works, which have grown to an enormous extent, still continue, and here some bronze metal machinery, cast under the superintendence of a foreign gentleman from the Mauritius, whom Colonel Galloway induced to settle in Calcutta in 1820, are still in operation. As our East Indian dominion became extended, fresh gunpowder works were established at Alahabad by Captain Taylor, but these, as well as those at Ishapore, were, from economical motives, suspended for three years, during the governor-generalship of Lord William Bentinck, and the former have never since been re-opened; a circumstance which our author thinks has turned out very fortunate, "as in the late mutiny and occupa-"tion of Alahabad by the mutineers, the most "serious results would have followed."

There is an interesting account of "The History of the first Establishment of Gunpowder in England," obtained by a careful study of the papers of the "Public Record Office," kindly permitted by Mr. Hart. The gallant editor thus closes this account:—"Al-"though the manufacture of gunpowder com-"menced in England in the time of Edward "III. (1345), it was not until the reign of "Queen Elizabeth, when the improved art was "imported from Flanders by the Evelyns, that "it was fairly established; also, that until the "reign of Charles II., the quantity required for "the king's service, and of saltpetre also, was "not sufficient, and that large quantities were "imported from various foreign countries."

By various Letters Patent, commencing in the reign of Elizabeth, several parties received permission "to dig, open, and work for saltpetre" in different portions of the realms of England and Ireland, and our author says, "It may be a wrong supposition, but with all "this digging for saltpetre, to the great distress "and worrying of the inhabitants of houses "in the town and country, gardens, orchards, "&c., which led to much discontent, probably "our great Shakespeare took the expression "(Act I., Henry IV.):—

"'And that it was great pity, so it was,
That villanous saltpetre should be digg'd
Out of the bowels of the harmless earth,'

"since the general practice in countries where "it abounds is to obtain it by lixiviation of the "upper soils."

On "The General Principles of Gunpowder," our author observes, "the first object in the "manufacture of gunpowder is to obtain, in "small space and weight, a material which "produces, when excited by chemical action, "a high propellent force, possessing an expan-"sive power which shall be gradual, progres-"sive, and under good control. Such is gun-"powder. Thus, the weight of 2 oz. will, in "its expansion when fired, propel 1,088 oz., "the weight of an iron ball placed before it "in a mortar, the distance of 100 yards" No substance yet discovered possesses these qualities so as to become a substitute for gunpowder. "It is a singular circumstance that, notwith-"standing the advance of science, and the "wonderful chemical progress of the moderns, "there has been no substance yet produced "that possesses all its advantages, and that the "three materials used in its composition from "the earliest times, viz., saltpetre, charcoal, "and sulphur, have not been superseded by "others." The gallant editor, in the appendix to the work, enters into the consideration of gun-cotton, compounds of nitrate of soda, nitrate of ammonia, and chlorate of potash, which have at different times been brought forward to supersede gunpowder, and fully confirms the opinion of the learned author.

"The Chemical Properties of Gunpowder" are fully discussed and will repay for very careful perusal.—"There can be little doubt that in "the first formation of gunpowder, when the "science of chemistry was comparatively un-"known, accidental circumstances led to these "properties (change from a solid to an expan-"sive gaseous or aeriform state by the appli-"cation of heat) being discovered in the "mixture of saltpetre, charcoal and sulphur, "probably in the first instance only saltpetre "and charcoal were used." Modern chemistry has, however, developed the properties in these substances which render them so essential in the formation of gunpowder. Saltpetre, or nitrate of potash, contains nitric acid 54, and potassium 46 charcoal and sulphur are regarded as simple substances, although it seldom happens they are pronounced pure. Gunpowder, therefore, consists of one compound and two simple substances. "The compound "(saltpetre) consists of nitric acid combined "with a base of potash. The nitric acid "consists of oxygen and nitrogen, six parts of "oxygen to one of nitrogen; when saltpetre "is exposed to a red heat, or above 800 deg., "it decomposes gradually, if there be no com-"bustible present, and a portion of the oxygen, "and all the nitrogen, will pass away into the "atmosphere; the other portion of the oxygen "will unite with the potash and form oxide of "of potassium; but when we bring a com-"bustible, as charcoal, into contact with the "saltpetre at this heat, a violent and sudden "decomposition takes place, and consequent "explosion, from its striking the air so sud-"denly. The oxygen combines with the "carbon, forming carbonic acid gas, and the "nitrogen is set free. It is found from experi-"ment that the volume of gaseous or aeriform "fluid thus formed, occupies a space, as a per-"manently elastic fluid, about 240 to 290 "times that of the bulk of the gunpowder "used, when cooled down to the state of the "atmosphere; but at the time of explosion the "heat generated is so great; that the expansion "of this volume of gas is increased from four "to eight times its bulk, varying according to "quantity and quality of the gunpowder and "the circumstances of the explosion. Such "is the cause of the amazing power of the "explosion." After this *rationale* we are informed of the parts the sulphur performs, viz., more complete combustion. the closing of the absorbent pores of the charcoal, and increased tenacity in the granulations, thus rendering it an essential element in the manufacture of good gunpowder. The proportions of these three substances next pass under review, and an instructive table is furnished, based on the theory of chemical equivalents. "And," says our author, "it is "a curious circumstance, that the resulting "properties of chemistry are nearly those "universally made use of by manufacturers "in early times." This the editor illustrates by a carefully-compiled and clearly-expressed table. It has been observed that one measure of gunpowder will yield from 240 to 290 equal measures of permanent elastic gas. If the temperature during combustion be as high as "2,196 deg. Fahr., this will create an expan-"sion, or a propulsive force of about 1,592 "atmospheres; taking the atmosphere at only "14½ lbs., there results the astonishing pres-"sure of 1,592 by 14½, equal to 22,074 lbs. "on the square inch of surface at the moment "of combustion."

Saltpetre abounds in India, but particularly in the presidency of Bengal. This is obtained by the natives, by a process fully described by the author. It is called culmer saltpetre, and is sold to the Gunpowder Agency, at Calcutta; it contains, however, a large per-centage of extraneous salts, which have to be removed before it is fit for the manufacture of gunpowder. This is accomplished by boiling and crystallization. Formerly, the boiling was repeated twice; but by the improved process now in use, one operation suffices. "The "usual impurities of unrefined saltpetre—as "nitrates and muriates of lime, with other salts "having bases of magnesia and soda—dissolve, "and remain in solution, equally, in hot or cold "water, and saltpetre has the property of "excess of solution, as the temperature is in-"creased. Advantage has been for some years "taken of this property, both in France and "at Madras, as well as the saving of labour "occurring in preventing large crystals being "formed by the slow process of cooling, by "keeping the solution in agitation during the "boiling, so as to obtain pure saltpetre, in the "state of fine meal, at one operation. This "new system of refining, has now been im-"proved upon, and adopted at the Royal Mills, "Waltham Abbey, and some other private "manufactories.

"A quantity of unrefined saltpetre, accord-"ing to the size of the manufactory, say 40 "cwt., is put into a copper boiler, holding 500 "gallons, with 270 lbs. of water, and brought

"to a boiling point; the impurities are carefully skimmed off as they rise, and a small additional quantity of cold water is occasionally thrown in, to assist in the precipitation of such salts are are not equally soluble with the nitre, as the temperature rises. After boiling about three and a half hours, the fire is damped, and those salts that have crystallized fall to the bottom. In about two hours a copper pump is used, to pump off the solution into a trough, properly provided with criks, to each of which a canvas bag of the jelly-bag shape, is attached, and the solution runs off through the canvas, into large troughs, 10 ft. by 6 ft. wide, 9 in. deep, lined with sheet copper, and is kept in a state of agitation with wooden rakes until nearly cold. Thus a large quantity of very minute crystals are formed, which are drawn up by a wooden hoe, and thrown by a shovel on a framework wire sieve resting on the opposite sides of the trough; here they are allowed time to drain, and have the appearance of fine white snow; when drained sufficiently the produce is raked over into a washing cistern, conveniently placed, which is 6 ft. long by 4 ft. wide, and 3 ft. 6 in. deep, fitted with a false bottom of wood, which is removable at pleasure." Here the saltpetre uudergoes two washings, and is, after a few hours, found, upon raising the bottom of the cistern, to be perfectly pure. The moisture it contains is thus evaporated in copper trays. The editor furnishes a list of the apparatus for thus refining in one day what formerly occupied six, and for producing 23 hundredweight of refined saltpetre *per diem*. This apparatus is, as he says, trifling in quantity.

We are next introduced to the process of preparing charcoal, which is illustrated by a finely-executed plate, representing a charcoal furnace. To test the purity of charcoal—"One hundred grains must be well digested in hot distilled water, when the solution of nitrate of silver and nitrate of barytes will indicate the presence of muriate and sulphate of soda if any exist. Acids will be rendered apparent by litmus paper. If the solutions contain any alkali, the original blue colour will be wholly or partially restored to the reddened paper."

On the refining of sulphur, the remaining constituent of gunpowder, after a full description of the mode practised in India, we are initiated into the new mode, as practised at the Royal Mills, Waltham Abbey. This is by distillation, and is considered the best for rendering the sulphur pure, and especially freeing it from all acids, which is of great importance. The purity of the sulphur is thus ascertained: a small portion is burnt, by exposing it to heat over a lamp, on a piece of porcelain or sheet platina, when no residue should be left, as the sulphur will pass off, in a state of vapour, into the atmosphere; if boiled in distilled water, the water should produce no discolouration in litmus paper.

The three ingredients, now being prepared and and sifted, "are conveyed to the weighing-house in proper quantities, where the man prepares them in the relative proportions of seventy-five-hundredths of saltpetre, fifteen-hundredths of charcoal, and ten-hundredths of sulphur for a mill charge of 80 lbs. He uses leaden weights of 30, 12, and 8 lbs., dividing the saltpetre into two parts, so as to confine the charcoal and sulphur between them. The whole is slightly intermixed, by hand, in a woooden box, carefully surrounded by a cloth covering, to prevent the escape of any of the light particles." Our author observes, "As the entire loss, by wastage, in the manufacture of the prepared ingredients is about 5 per cent. of the composition, perhaps it would be better if that per-centage were added at first to the mill charge, so as to conclude the process with the full 80 lbs. of powder."

The important processes of dry-mixing, incorporating the ingredients, bruising, pressing, granulating, sifting, glazing, drying, and packing, are next described. The ingenious and often delicate machinery employed is illustrated by accurately-finished engravings, most of which are drawn to a scale, and the various modes, quantities, and results brought vividly before the eye by means of carefully-compiled and clearly-executed tables.

(To be concluded in our next.)

LONDON BRIDGES.

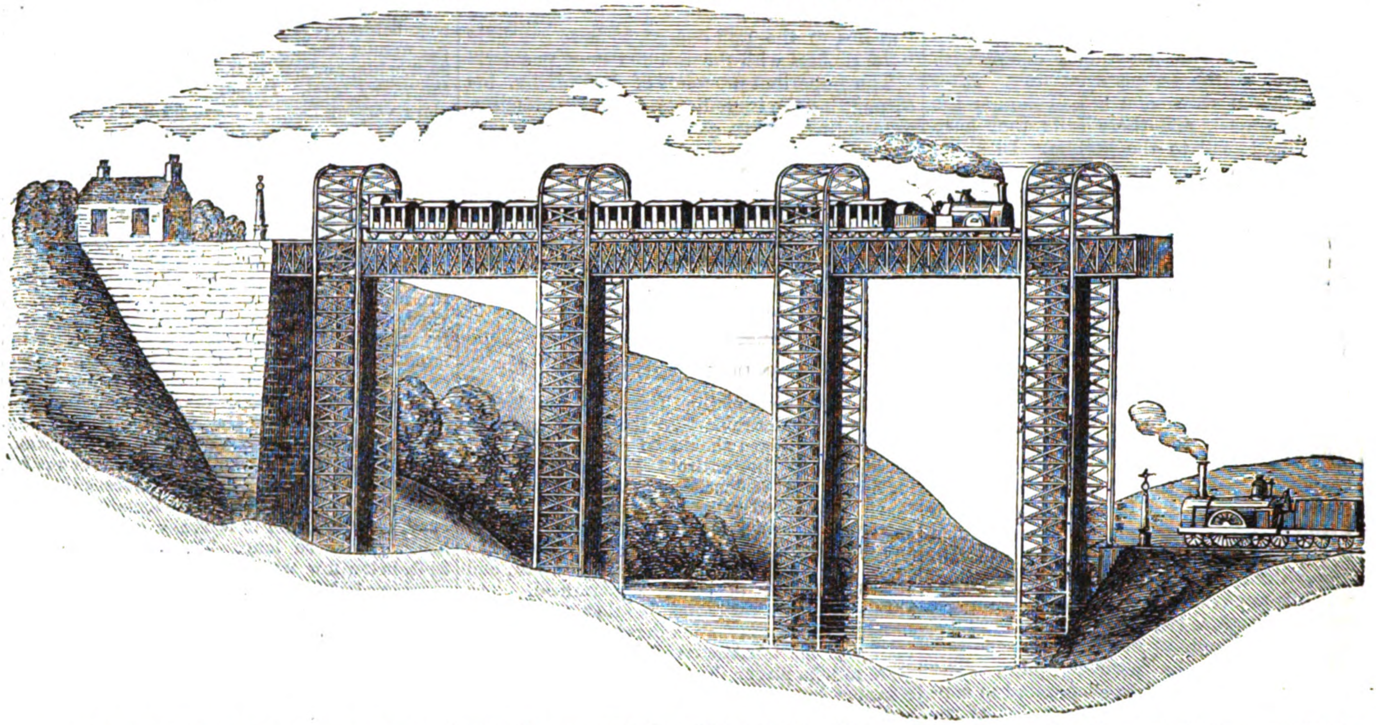
The construction of the Thames embankment will render it desirable that the whole question of London bridges should be reviewed and investigated in its entirety at an early date; for unless that is done, and provisions made to meet the altered *regime* of the Thames, due to increased scour and alteration in the direction of the currents, Londoners may awake some fine morning to find three of their bridges down, and the foundations of others undermined. The reader can more easily imagine than any pen can describe the consternation that would seize on all classes of the inhabitants if such a catastrophe were to take place. The bridges, whose foundations are insecure, and believed to be unable to resist increased scour, are Waterloo, Blackfriars, and Southwark. Engineers declare them liable to go at any time with a deepening channel, such as we shall have after the embankment is completed. The proprietors of Waterloo are nervously alive to the dangers which threaten the Surrey arches of their structure. Blackfriars is propped up, and as to Southwark, is not Robert Stephenson's opinion on record as to the ignorant and unscientific way in which it was designed and erected—the ignorance which made no allowance for the expansion and contraction of iron, according to the variations of temperature, and which have resulted in the splitting and fracture of nearly every part of the fabric? Even London bridge itself is not considered positively secure, and it will be remembered that the late Mr. Rendel, together with Mr. Simpson, declared that new Westminster was not founded deep enough to place the supports of the piers below the level to which the action of the scour might penetrate hereafter, and during the time the edifice might be expected to stand. Although the anticipated scouring effect of a contracted channel may have been exaggerated, and we believe Mr. Page, designs will attain the average duration of existence of like works, the dangers to the three bridges named above remain the same. We do not mean to assert that they will tumble down into the bedof the river before a certain date; but if they be allowed to remain as they are such an occurrence comes within the range of probabilities. Or, if they do not collapse into heaps of rubbish, they are still more likely to crack, from subsidence of the foundations, and become impassable, while they will, at the same time, seriously impede the navigation of the Thames.

Let us see how they have been built.

It certainly does not argue much for the activity of the trade of London, nor for the prudent attention of the inhabitants to its requirements, that, during the whole of the Middle Ages, and indeed until about a century ago, there should have been only one bridge over the river. Ancient Rome had eight, and Paris, under the reign of Henry IV., had six. Even as it was old Lond on bridge could have afforded but very slight accommodation to traffic, until the houses that were built on it, and encumbered the way, were pulled down in 1760. It was a curious quaint structure, such as our grandfathers may have beheld before the alterations were made by Dance and Taylor, and as the old curate of Colechurch designed it. Hawksmoor says the river here was 900 ft. across, and at the water-way below the starlings was no more than 190 ft. No wonder it acted as a dam. It was 296 ft. long, 20 ft. wide, and was 40 ft. high in the centre above the water level. It had 20 arches, carried on piers varying from 25 ft. to 34 ft in thickness; a chapel in the centre, and at each end a fortified gateway, which was generally well garnished with heads of so-called traitors. So difficult were the approaches, that when the houses at the Southwark end took fire, at the commencement of the thirteenth century, and those at the north end were fired, upwards of 3,000 people perished. The roadway passing between two rows of houses that shut the river out from view, was not only troublesome, but dangerous, says Stow; and to augment the dangers of this middle passage, a market was held at one time on the bridge. A curious in the old edifice was the enormous thickness of the superstructure. The roadway was 8½ ft. above the crowns of the arches and had apparently risen by the accumulations of five different strata, one of which was composed of burned wood, the *debris* of the houses that had been destroyed by fire. The foundations were very defective, and it is really surprising they held together so long. The masonry was but 2¼ ft. below low water mark, and rested on oak planking 16 in. wide by 9 in. thick, which in turn was supported by a mass of Kentish rubble, mixed with chalk and flints, thrown in and held together by starlings. Parts of the piers had been faced at some early period, but very ill and carelessly, and no part of the original work rested on piles.

Although in subsequent bridges bearing piles have been used, it is not improbable that their absence in the old bridge was the cause of its standing so long; for, after all, piles do disturb the ground and break it up, when compact as London clay is. In new London bridge the masonry of the piers rests upon 6 in. beech planking, laid on two rows of horizontal sleepers, about 12 in. square, that cover the tops of piles driven 20 ft. into the London clay. The foundations of Waterloo are also supported on beech and elm piles, of the same size and depth as those of London bridge, having sleepers at top, to hold them together, to which a timber flooring was spiked. The piers of Southwark bridge are seated on the clay, we believe, but are enclosed by timber sheet piling. Blackfriars was built on fir piles; and as for old Westminster Bridge, its novel system of founding was a failure from the first; but whether that was due to Labeye not using piling to the piers, or to his caissons, cannot be satisfactorily determined now. It is for this reason that it will be desirable to watch the behaviour of the piers employed in Lambeth and Charing Cross bridges; for if they are found to stand well, and to afford no indications of settlement, bridges may be built over the Thames at comparatively trifling cost, and without impediment to its navigation. London bridge, with the approaches, cost nearly two millions, while Mr. Barlow proposes to build one of his wire suspension bridges at Tower Stairs for something like £50,000. It wiil not be much longer than Hungerford Chain bridge, which cost £180,000. Certainly, if this gentleman be successful, and enabled to construct the two other bridges which he has suggested at Paul's Wharf and Essex-street, London's want of bridges will be pretty well remedied; but unfortunately they will levy tolls, and there will be only three toll free. Now it is really unworthy of a city like London, that tolls should be taken within its limits; for they are a serious tax upon traffic, and tend to divert it from its natural channels. The money which the corporation proposes to spend in erecting Mr. Cubitt's design at Blackfriors would suffice to erect five according to Mr. Barlow's system. Surely it would be better, until after Lambeth bridge has been open for some time for traffic, to ascertian the stability of the structure, and, if found satisfatory, to adopt the new system of construction, in order to give us half a-dozen new bridges in the place of one.—*Building News.*

AERO-HYDROSTATICAL HOISTING APPARATUS.



AERO-HYDROSTATICAL HOISTING APPARATUS.

In the western annexe of the International Exhibition is to be seen two models, illustrating an apparatus for hoisting and lowering heavy weights, such as railway trains, from one level to another. The apparatus is termed an Aero-hydrostatical Balance. The inventor, Mr. Sieler, states that the model has only lately been placed in the building, therefore the jurors could make no mention of it in their report. The principle of the apparatus, which will be partially understood by the engraving, is based upon the displacement of water and of enclosed columns of air, in communication with each other by a tube, and set in motion by a surplus weight, which consists, generally, of a volume of water. When ponderous bodies are to be alternately and intermittently raised and lowered to or from either small or great vertical heights, such as, for instance, a whole railway train, there needs but a surplus weight of from 3 to 10 per cent. (according to the desired speed) of the whole weight to be hoisted or lowered, to enable that same weight to ascend or descend, whatever may be the space of time between each train.

The surplus weight necessary to lower the balance may, in most cases, be procured from an approximate or distant rivulet or stream, made to accumulate its water in a reservoir; no matter whether it be at a much lower level than the ground on which the apparatus stands.

The models before mentioned represent a bridge, upon which stands a railway train, to be raised to a height of 115 feet in less than five minutes, and is made to work by means of a tube 100 feet in length, leading from an air holder.

In full size, it would consist of two cylindrical air chambers or holders, 11 yards in diameter, having together a surface of 180 square yards, upon which rests a bridge bearing a train which, with the weight of the immersed air holders, weigh 550 tons. A 3-feet-diameter tube, provided with a stop-cock or valve, puts them in communication with a *main acting chamber* or motor of an equal surface, 180 square yards, on the top of which is fixed a tank, made to contain sufficient water to equilibrate the 550 tons weight of the train. This acting chamber may be placed anywhere, at any distance where water can be had, and stands between two reservoirs, easily formed one above the other, from which water is procured for adding to the different loads of the train, a surplus weight which enables them to be hoisted or lowered.

The inventor gives the following example: Take from the lower reservoir sufficient water to equilibrate the weight of 550 tons, and force air into the three chambers until double the weight of water, 1,100 tons or 1,440 cubic yards, be displaced from their inside. From this moment, the resistance of the weight is overcome, that is to say, that the entire load floats on the air, which has thereby acquired a tension of 6½ feet of water, or a little above ⅕ of an atmosphere. Then shut the cock and continue to force air into the acting chamber only, until it raises out of the water and reaches a few inches under the level of the upper reservoir. It must be observed that the difference existing between the weight of the acting chamber when in and mostly out of water, is only 8 tons, therefore the amount of the surplus water thus displaced from within the acting chamber is very trifling compared with the immense weight to be lifted or lowered. When once the required bulk of air is forced in, it may be used over and over again, and any escape which may occasionally take place is easily replaced by an ordinary hand air pump. The railway train is made to ascend, by first letting water flow from the upper reservoir into the tank of the acting air chamber, until it is loaded with 5 per cent. above the weight to be hoisted, say 27 tons, and afterwards by opening the stop-cock. This causes the air to be driven into the two air holders in less than *five minutes*, during which the train ascends a height of 115 feet, whilst the acting chamber descends to the level of the lower reservoir. The cock must then be shut, and the train started off. Whilst waiting for the arrival of a train to be lowered, it is necessary to regulate the difference which may exist between the weights of the going and the returning train (always known before-hand.) by either adding water to the tank of the acting chamber, or removing some of it, in order that the train to be lowered may always weigh 5 per cent. above the volume of water to be lifted up by the acting chamber. Several successive trains may also be lifted up or lowered, with a loss of only 5 per cent. of water, by using a couple of acting air chambers, but if there be plenty of water one alone will do.

Mr. Seiler has also designed an aero-hydrostatical apparatus, for instantly raising out of water any floating dock containing ships of any size to be repaired; it will practically be more effective, simple, more handy, and cheaper than any other, because no foundation or masonry of any kind will be required to erect it. Being movable, and floating on air, it can be towed anywhere, in a dock, river, or the open sea.

Mr. Seiler has entered into a contract with some first-rate engine and iron bridge builders in France for the construction of his apparatus, and also wishes to find an opportunity to apply it in England, being fully satisfied that it may render valuable services.

ON THE CHEMICAL EXAMINATION OF IRON SAMPLES, AND OF THE MATERIALS EMPLOYED IN THEIR MANUFACTURE.*

By F. A. Abel, Esq.,

Chemist of the War Department.

(Continued from page 176.)

Phosphorus.—For the estimation of phosphorus, 50 grains of iron borings were acted upon with warm nitro-hydrochloric acid, in a flask with a long neck, and after complete solution of the metal, the contents of the flask were transferred to a porcelain basin and evaporated to dryness; the residue was moistened with concentrated hydrocloric acid, and again evaporated, so as thoroughly to expel nitric acid. The residue then obtained was dissolved in hydrochloric acid, the solution diluted, filtered, nearly neutralized with carbonate of ammonia, and the iron in solution reduced to protoxide by the addition of sulphite of ammonia to the gently heated liquid, and the subsequent careful addition of dilute sulphuric acid to expel excess of sulphurous acid. Acetate of ammonia, and a few drops of solution of sesquichloride of iron, were then added, and the liquid boiled, when the phosphoric acid was precipitated as basic phosphate of sesquioxide of iron, with some basic acetate. The liquid was rapidly filtered, with as little exposure to the air as possible, the precipitate was slightly washed and dissolved in hydrochloric acid, the solution neutralized with carbonate of ammonia, and a mixture of ammonia and sulphide of ammonia added; it was then gently heated, to ensure the conversion of the phosphate into sulphide of iron. The latter was afterwards removed by filtration, washed with dilute sulphide

* Report of Experiments on British Irons, Ores, &c., for the Manufacture of Cast Iron Ordnance.

of ammonium, and the phosphoric acid was precipitated from the solution in the usual manner as ammonia-phosphate of magnesia, and weighed as pyro-phosphate of magnesia, from the amount of which the phosphorus was calculated.

Combined Carbon.—After numerous comparative trials of the several methods in common use for determining the total amount of carbon in cast iron, that which was ultimately adopted (after necessary experiments had fully established its accuracy) consisted in dissolving the metal in an acid solution of chloride of copper, collecting and washing the insoluble residue which remained after the complete action of this solvent, and submitting it, when dry, to combustion with oxide of copper in a current of oxygen, the source of heat employed being the gas combustion furnace. The total amount of carbon in the iron was then calculated from the weight of carbonic acid absorbed by solution of potassa in the usual manner. The carbon, existing in a state of combination with the iron, was represented by the excess which this process afforded over that of the direct estimation of the carbon as graphite, in the manner already described.

Minute Proportions of Foreign Metals.—About 400 or 500 grains of the iron were employed in the examination for metals precipitated by sulphuretted hydrogen, *e. g.*, lead, copper, arsenic, &c. The iron was dissolved in hydrochloric acid, and the solution, diluted and partly neutralized with carbonate of soda, was submitted to the action of sulphuretted hydrogen. After saturation with the gas, the liquid was allowed to stand at rest for several hours, and the small quantity of sediment which had subsided was examined for metals by the ordinary analytical processes.

II.—ANALYSIS OF THE IRON ORES.

The analytical processes employed in the separation of the various constituents occurring in iron ores were, in a great measure, identical with those employed in the examination of metallic iron. Thus, the estimation of oxide of manganese was conducted in a precisely similar manner; and with the exception that no process of reduction was required in the case of clay ironstones and other ores containing the iron already in a state of protoxide, the phosphoric acid was determined by the same process as that employed for the estimation of phosphorus in pig iron. The amount of metallic iron, and its condition of oxidation in the ore, were determined by Marguerritte's volumetrical method, with standard solution of permanganate of potassa; while the proportions of lime and magnesia, carbonic acid, water, hygroscopic and combined, insoluble residue, and the nature of this latter, were determined by following the analytical processes invariably employed in mineral analyses of this description.

Sulphur was estimated by fusion of the ore (or, in the case of clay ironstone, of the clay only) with a mixture of pure carbonate of soda and nitre; the sulphuric acid being precipitated by chloride of barium, from the acidified solution of the fused mass, and the sulphate of baryta collected, burnt, and weighed as usual. The hydrochloric acid solution of the ironstone was examined for sulphuric acid, but it was seldom that more than a trace of sulphur was detected in that form.

III.—ANALYSIS OF THE SAMPLES OF FLUXES.

These materials, consisting of limestone, burnt shale, &c., were analysed by a method precisely similar to that employed in the examination of the ores. In the tabulated statement showing the composition of the limestones, the amount of lime is, in some few instances, represented by the difference, after the whole of the other constituents had been determined. In such cases the sum total of constituents is necessarily expressed by 100 exactly.

IV.—ANALYSIS OF THE SAMPLES OF FUEL.

Sulphur.—For the estimation of sulphur, 20 grains of the finely-powdered coal or coke were fused in a platinum basin, with 500 grains of a mixture of four parts of pure chloride of sodium, two of nitrate of potassa, and one of carbonate of soda. The filtered aqueous solution of the fused mass was acidulated, precipitated by chloride of barium, and the sulphate of baryta, collected and weighed.

Ash.—The ash left on burning a weighed portion of the coal or coke was also determined, and its composition ascertained by qualitative examination.

Results of the Chemical Examination of Iron, and Materials employed in its Production.

A special report has been drawn up on the results of the analytical examinations of each set of samples received from the various works.

To facilitate a comparison between the composition of the irons, ores, &c., tabulated statements have been prepared, of the following description:—

Table I. embraces the numerical results obtained in the examination of the samples of iron.

Table II. exhibits the per-centages of the most important constituents of the various ores; and, Table III. includes, similarly, the principal results obtained in the examination of the fuels and fluxes.

The following are a few remarks which have suggested themselves upon an inspection of these tabulated results:—

The specimens of iron prepared from the ores of the northern district and from the forest of Dean, are remarkably free from phosphorus. This is readily explained by the very high quality of these ores, which are almost perfectly free from phosphoric acid. The considerable per-centage of silicon contained in a great number of the specimens of iron alluded to, is perhaps less easy of explanation. A reference to the composition of the specimen of Ulverston (Hæmatite) iron, given in the appendix to this report, which was smelted with charcoal, and only contains 0·59 per cent. of silicon, would appear, however, to indicate definitely that the high proportions of silicon must be ascribed to the employment of hot blast in the reduction of the iron at those works.

The products of the ores from South Staffordshire and South Wales which have been examined are, with two or three exceptions, of excellent chemical quality. Only three instances occur in these divisions of the series of iron samples (out of 26 samples from eight different works) in which the amount of silicon reaches two per cent. The samples from the Netherton and Old Hill Works (South Staffordshire), and the Blaenavon and Pontypool Works (South Wales), in the preparation of which cold blast is specified as having been employed, the silicon in only two instances (out of 13 varieties of iron) slightly exceeds in amount 1·15 per cent.

The proportions of phosphorus and sulphur in irons from the ores of this district are also inconsiderable in the majority of the samples examined. In the case of three only (out of 26) does the amount of sulphur reach to one-tenth per cent., and the phosphorus amounts to less than 0·5 per cent. in 20 instances; of the other six, three contain less than 0·6 per cent.; one from the Old Hill Works contains 0·63 per cent; and two samples from Brierly Hill Works contain 0·63 and 0·72 per cent. The ores employed at the latter works contain somewhat higher per-centages of phosphoric acid, the effects of which on the composition of the iron produced are, therefore, clearly traced. The per-centages of phosphoric acid in the ores used at the Old Hill Works (particularly in the "Balls," Bilston) are also higher than those in most of the ores used at the remaining South Staffordshire works, and its influence on the quality of the product is, to some extent, shown by a reference to the composition of some of the irons from those works.

That the proportion of phosphorus in the iron is not always determined by the proportion of phosphoric acid existing in the ore employed, need, however, be scarcely pointed out. The fact may be exemplified by reference to some of the samples of iron from the works last alluded to, and to the iron from the Lays Works, near Dudley, in which the per-centage of phosphorus is small, while the phosphoric acid in the ore is comparatively high. The circumstance that the proportion of phosphorus in all the samples of iron from the Blaenavon Works is small, while several of the ores employed contain considerable quantities of phosphoric acid, is probably to be ascribed to the employment of cold blast in the reduction of the iron at those works.

The oolitic ores and the clay ironstones employed at the works in the North Midland and North Staffordshire districts, from which specimens were submitted, as also the ochrey brown ironstones employed at the Northamptonshire Works, contain proportions of phosphoric acid, which are more considerable than those existing in the greater number of the other ores examined. Thus, the ore employed at the South Bank Furnaces contains nearly two per cent. of phosphoric acid; that used at the Stockton Works contains upwards of 1·5 per cent., and very nerly the same amount exists in one of the ores at the Butterley Works, and in that employed at the Goldendale Works (North Staffordshire). The proportions of phosphorus in the various samples of iron from these sources exceed one per cent., except in one sample from the Butterley Works, in which, however, it amounts to 0·72 per cent.

The samples of iron produced from Northamptonshire ores also contain more that one per cent. of phosphorus; the proportions of phosphoric acid in the ores are, however, not quite so high as those last alluded to, amounting to 0·84 and 1·03 per cent. The samples of iron from one of the works (the East End Iron Works) are, moreover, stated to have been produced with cold blast.

The North Staffordshire ore, used at the Goldendale Works, contains nearly 1·5 per cent. of phosphoric acid, and the proportion of phosphorus in the iron produced from it just exceeds one per cent.

A general inspection of the results obtained in the examination of the samples of ores and of the iron varieties produced from them, appears to justify the following conclusions, upon which metallurgic chemists are now tolerably well agreed:—

1. The proportion of silicon in iron is much less influenced by the constitution or quality of the ores employed than by the conditions of smelting. A reference to the composition of the Northamptonshire ores and iron samples (particularly those from the Heyford Works), indicates that under certain circumstances, among which may probably be included a deficiency in alumina in the ore or the flux employed, an ore containing much silica is very liable to furnish a highly siliceous iron.

2. The proportion of sulphur existing even in light grey pig iron is never so considerable as to exert an appreciable influence on the properties of the metal; and none of the descriptions of British ores which have been examined in connexion with this report contain an amount of sulphur compounds sufficient to exert any prejudicial influence on the quality of iron produced from them.

3. The proportion of phosphorus in iron is, in great measure, determined by the per-centage of phosphoric acid in the ore employed, while, at the same time, it is probably to some extent regulated by the temperature at which the reduction is effected (*i.e.*, by the employment of hot or cold blast.)

The various ores examined, if classed according to the per-centage of phosphorus in the iron reduced from them, would stand in the following order:—

No. 1. Northern District and Forest of Dean ores, used by the Whitehaven, Weardale, and Parkened Works.

No. 2. South Staffordshire ores, used at Netherton, Parhead, Old Hill, Lays, and Level Works; South Wales ores, used at the Ystalyfera Works; South Wales ores, smelted with cold blast at the Blaenavon and Pontypool Works.

No. 3. North Midland ores, used at the West Hallam Works.

No. 4. Northamptonshire ores, used at the East End and Heyford Works; North Stafford-

shire ore, used at the Goldendale Works; North Midland ores, used at the Butterley Works.

No. 5. Cleveland ores, used at the South Bank and Stockton Works.

It will scarcely be out of place to conclude these few remarks on the results of the analytical examinations with some notice of the very considerable difference observed in the structure of many of the samples of iron analysed, and particularly in the physical condition of the so-called graphite, as exhibited by fresh fractures of the metal. In some instances a grey iron containing a per-centage of graphite similar to, or even higher than, that in the second sample exhibited a dense compact structure, while that of the other sample was open grained, and showed the existence of the graphite in larger and distinct scales. These modifications in the structure of pig iron are so well known that they are only alluded to because it is to them that must undoubtedly be ascribed, in many instances, the apparent discrepancies (which may be noticed by a comparsion of the results included in this report) between the chemical quality of a sample of iron and the results which it has furnished when submitted to mechanical tests. It is self-evident that a sample of grey iron, compact and uniform in structure, may resist the application, for example, of a much more considerable tensile strain than one which is of higher chemical quality (*i.e.*, containing less silican or phosphorus, but of which the structure is comparatively open and irregular. There is little doubt, also, from the results of numerous experiments which have been made in this direction, that the effect of adding considerably to the strength of some kinds of cast iron by repeatedly re-melting them is, within certain limits, due to no important chemical change effected in the iron, to the gradual production of a more thoroughly uniform mass, in which the graphitic carbon has gradually undergone a material change in its state of aggregation.

BRICKHILL'S IMPROVED CYLINDER AND PISTON FOR STEAM ENGINES.

BRICKHILL'S IMPROVED CYLINDER AND PISTON FOR STEAM ENGINES.

FIG. 1.

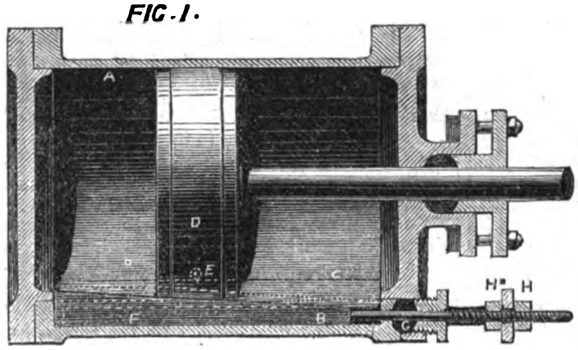


FIG. 2.

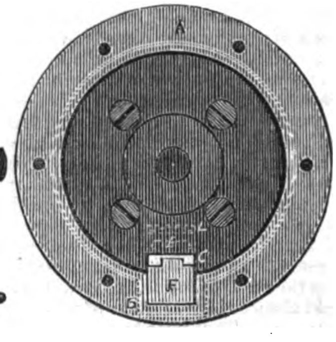

FIG. 3.

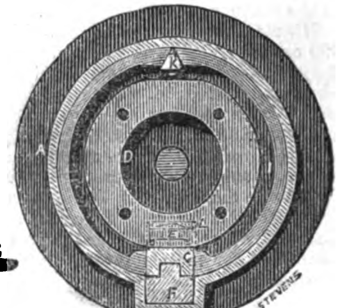

FIG. 4.

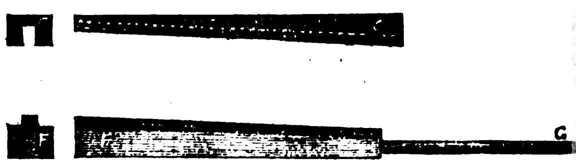

THIS invention, just patented by Mr. W. Brickhill, of Stepney Causeway, is applicable to locomotive engines, and to such stationary, marine, or other steam engines as have their cylinders placed in a horizontal or inclined position.

The object of the invention is to obviate or prevent the great friction of the piston on the lower side of the internal circumference or "bore" of the cylinder, and thereby to reduce the amount of wear, and consequent leakage to which such engines are liable, as well as to reduce the quantity of steam necessary to effect each stroke of the piston.

The improvements consist principally in forming a longitudinal groove in the lower side of the interior of the cylinder, and in placing therein a long key or "feather," on which a corresponding groove or notch in the piston works. A small fricton roller (let into the piston) runs on this key or "feather," and supports the whole weight of the piston, thus obviating the friction of the piston on the lower part of the cylinder. The under part of the key or "feather" is inclined, and a corresponding wedge is placed below the same in the groove, such wedge being attached to a rod passing out through a stnffing box in the cylinder cover, so that by forcing the wedge forwards by means of a nut on the screwed end of the rod, the whole surface of the key or "feather" may be raised perfectly parallel, to compensate for any wear that may take place.

The piston is packed by means of two half rings of metal, expanded by means of a wedge, the lower ends of the half rings embracing the sides of the key or "feather." and keeping the joint steam-tight; the upper surface of the key, or "feather" is packed by means of a packing piece sliding in a groove in the piston, and pressed downwards by means of a spring.

Fig. 1 of the above engraving is a longitudinal section through the cylinder; Fig. 2 is an end view of the same, with the bottom plate of the cylinder removed; and Fig. 3 is a transverse section of the cylinder and wedges, showing the bottom plate of the piston removed. A A is the cylinder, which is cast or formed with a longitudinal groove or trough, B B, in its under side, running from end to end. In this groove B, B, is placed a long key or "feather" C, C, on which a corresponding groove or notch in the piston, D D, works, the weight of the piston being borne on a small friction roller E, running on the key. The under part of the key or "feather" is inclined, and a corresponding inclined wedge, F F, is placed below the same in the groove, such wedge being attached to a rod G, passing out through a stuffing box in the cylinder cover. The under surface of the key, and the upper surface of the wedge, are respectively tongued and grooved, as shown in the detached views of the same. Figure 4. Upon drawing the wedge, F forwards by turning the nut, H, on the screwed end of the rod, G the whole surface of the key or "feather," will be raised perfectly parallel, so as to compensate for any wear of the lower side of the cylinder that may have taken place. H is a lock nut to hold the wedge firmly when adjusted. The piston is packed by means of two half rings, I I, of metal, expanded by means of a wedge, K, the lower ends of the half rings embracing the two sides of the key or "feather," C C, and keeping the joint steam-tight. The upper surface of the key or "feather" is packed by means of a packing piece, L, sliding vertically in a groove in the piston, and pressed downwards by means of a spring. This piece, L, may be made wider than the key, and its edges fitting into grooves in the lower ends of the half rings.

NEW METHOD OF PREPARING IRON PLATES.

AMONG the many new plans for preparing iron plates for ships' sides, may be mentioned an invention by Mr. Mattison, of the Devonport dock-yard. It has been thus described:—The first process, taking the mould for the curve of the plate, is effected by what is termed an "Ordnance box"—that is, a wide piece of iron standing on its edge, through which a number of movable bolts are placed. On the points of the bolts being fitted against the side of a ship they are pressed home into the hollows of the curve until the exact shape is obtained. They are then fastened by screws and thus rendered immovable. In connexion with taking the mould is another instrument, for obtaining the levels and curved edges of the ship's side. It is made of slight polished iron, exceedingly flexible, so that it readily conforms itself to the curve when by movable pieces of iron, crossways and lengthways, the levels are taken. The instrument, on being removed returns immediately to its original flattened shape, the edges only retaining the peculiar form given to it by the ship's side. This instrument is for the levels only, the curve of the ship's side being obtained by the other. The mould being thus taken, is transferred to the machine that actually makes the curve, which consists of a kind of iron box filled with what are termed "peppots," that is, a number of pieces of iron about an inch square and 10 inches long. These, by screws in the bottom, can also be lowered or raised, and the mould being placed on the top of these movable pieces of iron, the exact shape of the curve is secured, and the "peppots" are screwed into their proper position. Another framework, containing similar pieces of iron in a converse position, is suspended over the one already described. When the plate to be curved has to be laid on, the lower framework is drawn out on a kind of rail; the plate, after being heated, is laid on the top of the "peppots" and drawn into its former position, when, by means of a lever, the upper "peppots" are brought down with such power as to secure the reqnired shape. The model is 20 inches wide, 30 long, and 42 high. The plan is said to possess great advantages over the one now in use for taking the curves by means of wooden moulds, which are usually 3½ ft. wide, and 4½ ft. thick, and about 15 ft. long. These moulds are cumbersome and costly. Mr. Mattison's plan has been submitted to Rear-Admiral Sir Thomas Pasley, superintendent, and other officers of the Devonport and Keyham yards, who are understood to have expressed their approval of the invention. The model is to be sent to Woolwich to be tested.

DEFLECTIVE ARMOUR FOR SHIPS OF WAR.

Fig. 1.

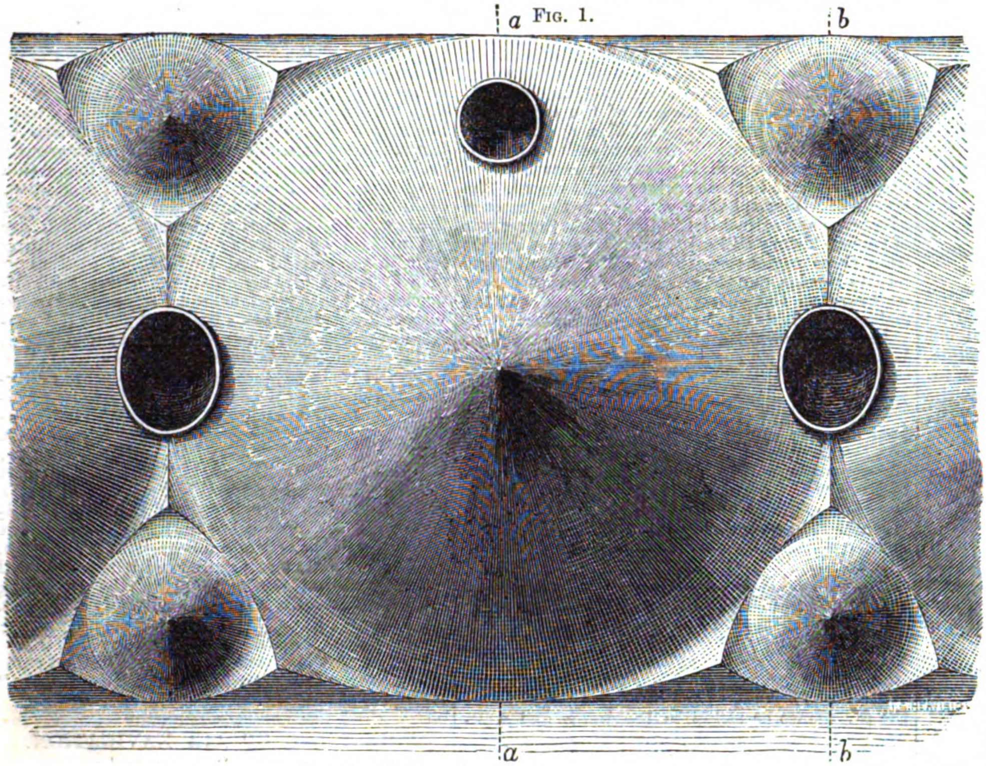

Fig. 2. Section at *a*, *a*.

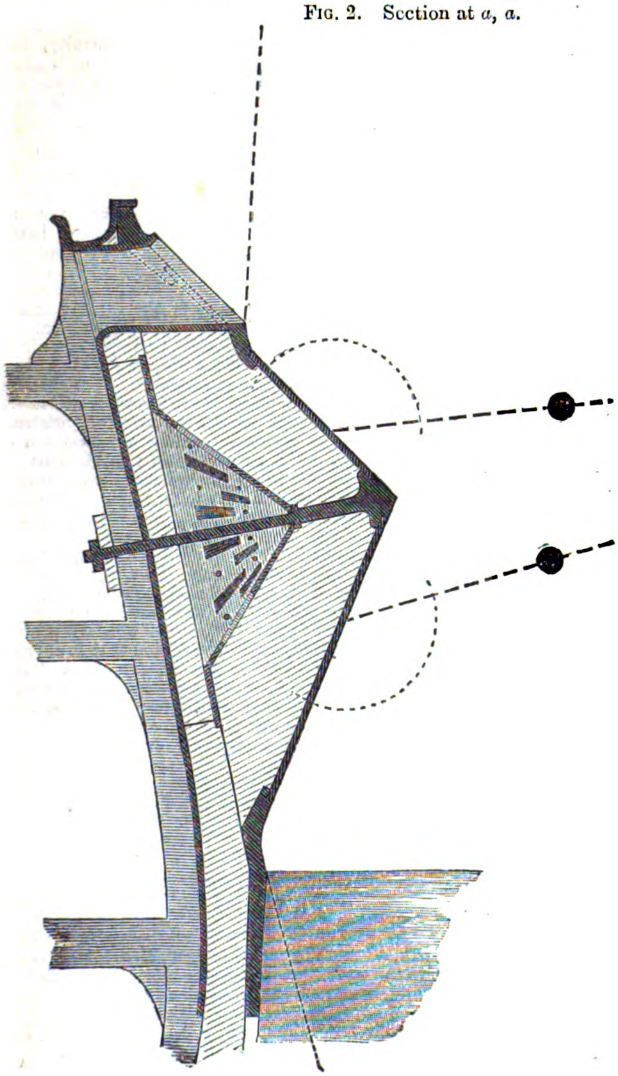

Fig. 3. Section at *b*, *b*.

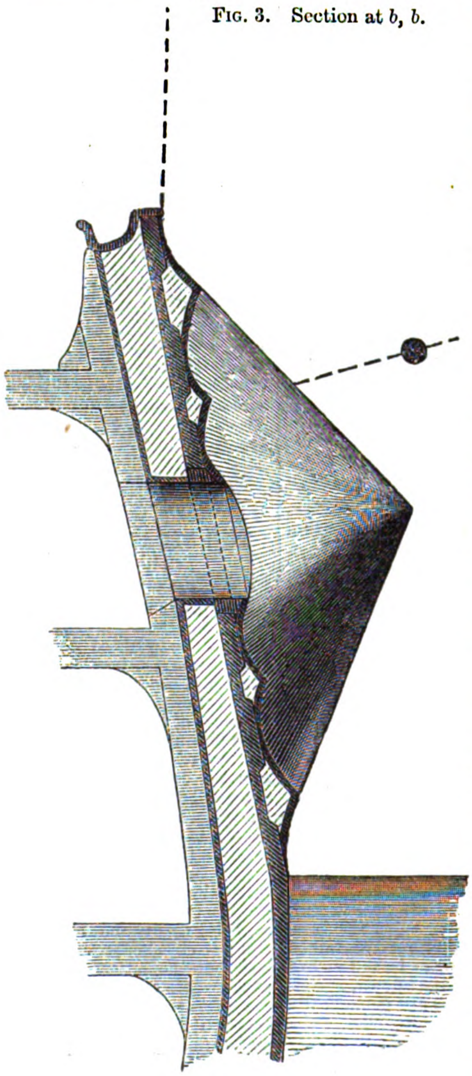

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

The late experiments at Shoeburyness should, I think, convince us that flat iron plates, of whatever thickness, are the most unscientific armour that can be used for ships of war—they receive the shot point-blank. In the second vol. of the "Transactions of the Institution of Naval Architects," published in 1862, I stated that it would be the duty of every artillery engineer officer in Europe to produce guns that will be able to crush these flat plates. The plates may soon reach their utmost thickness, while to the increased offensive power of the gun there will be no stop. However able our ships may be to meet in fair fight, in the open sea, vessels of similar description, covered alone with flat iron plates, they could not approach an enemy's fort, or enter his harbour; they would be inadequate to resist the heavy crushing effect of rifled guns, and the enormous strength of the modern artillery prepared ready to receive them.

It is a well-known fact that shot in motion are deflected in planes inclined to their course; that the more powerful the shot the more certain the deflection of it is prevented giving a point-blank blow. Your valuable correspondent, "Civilian," in page 31 of your journal, admitted this to be correct. He doubted whether the form.of armour I suggested would lessen, as I first imagined, the weight or thickness of iron. This, however, I consider secondary—the first point to be gained is the proper scientific form; this attained, after experiments, might settle the necessary thickness and weight of the shields.

The form I propose is to lay hold, to its full extent, of the principle and power of deflection. I apply the armours not in the shape of flat iron plates, but in the form of shields, of a projecting conical form, each shield having slightly-curved projecting tips, or bases, causing every shot that strikes it to glance, or deflect off in a backward direction towards the quarter from whence it came. The porthole I make either circular or oval, and place or continue the same circular tip round ,them, so that shot glancing over the surface of the shield should be deflected from them. Fig. 1 is the representation of a portion of a vessel's side, from porthole to porthole. Fig. 2 is a section of the same, at *a a*; and Fig. 3, a section at *b b*. The side of the vessel to which the shield is attached forms an angle of 85° with the line of flotation; the upper side of the shield, an angle of 45° with the same line. The black spots shown in Figs. 2 and 3 represent 10-inch shot striking the target and glancing off in the direction of the dotted lines. A shot to strike the lower side of the shield would come at a greater inclination than it

it struck the upper part; the angles, therefore, at the points struck would be about equal.

Now, it is evident that unless a shot striking the shield or target observed two conditions—its diameter being in the same plane with the diameter of the target, and its course an exact right angle to the part struck—it must glance off, whether it came vertically, straight, or oblique; whether it would deflect backward, take an inclination from the curved lip, and return like the boomerang of the Australian savage, towards the quarter from whence it came, must be subjected to proof. It would depend probably upon the greater or less projection of the lip itself; a bold projection might be struck off; a very slight one deflect the shot a mile away.

The shields might be constructed in many various ways. I do not give the present representations as the best that could be offered; but merely intend them to illustrate the principle. The projection allowed the shields would be regulated by the greater or less obliqueness of the sides of the vessel to which they were attached; where they had a bold projection, as shown in the figures, their metal covering need not be of uniform thickness. The figures show 6-inch thickness for the flat part, or lip of the shield, and 1½-inch for the projecting part; the whole being securely backed on timber, and screwed to an inner framework of iron. The shields could be made of a size sufficient to cover two or more fighting decks, placed in two lines, one above another, or dropped six feet below the line of flotation. They may be either oval or circular. The shields can be made either to form part of the construction of a ship, in combination with its framing, or they can be made so that they can be taken off and applied at will. Any alteration in the form and appearance of our present ships of war would certainly not be conducive either to their elegance, or to their sailing capabilities, and it demands more than ordinary courage to advocate any alteration. The love of the old form may be the true cause why thick iron plates, which do not injure it in any way, are used; but now that these plates are found inadequate to resist the heavy crushing power of the artillery that will most certainly be constructed to meet them, a more fitting iron construction ought to be introduced—one that will look like, and really be, a coat of mail—advancing the ship more nearly to the form and shape of the classic Roman galley. In suggesting such a form, I trust that the importance of the subject will obtain for it the earliest consideration of all interested in the question.

C. J. RICHARDSON.

34, Kensington-square.

Correspondence.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

SIR,—I have read with much interest in your last number an important paper on the "Conformation of the Alps, by Professor Tyndal, F.R.S." When Professor Tyndal writes about the Alps, he arrests the attention of every one interested in geological studies; but it nevertheless appears to me that he is very far from correct in attributing the glacial period to a great elevation of the "uplifted land," and in supposing that glaciers have gradually abraded the surface to the present level.

The decrease in the level—necessary for the change of temperature causing this diminution in the size of the glaciers—would be indubitably above three-quarters of a mile in vertical measurement; and even supposing that one-half of this depression were caused by subsequent subsidence, there would remain three-eighths of a mile, or about 2,000 feet, due to the glacier action; and during such enormous abrasion all trace of the first pristine moraines would necessarily have disappeared, whereas they appear to be clearly discernible up to the present day, for they form the base on which our distinguished Professor raises his most interesting superstructure. There is, however, a theory which I have entertained for many years, and which, during at least the last fifteen, I have done my best to make known, in conversation, to such of my friends as are geologically and scientifically inclined, in order to elicit from them some objection which might lead me to modify or abandon it if it could be shown to be in any wise untenable, and as yet no one has brought forward anything that has shaken my adherence to it.

My theory (for the idea will not admit of proof) is, that in some cataclysm which, in remote ages, convulsed that volcanic strip of land which connects North and South America, that neck entirely disappeared and sunk below the sea level, leaving sufficient clear space for the passage of the entire gulf stream towards the shores of China and Russian America and Siberia. Were we to seek for an approximate era in which to place this convulsion of nature, we have in those regions ample record. The travels of Atkinson have revealed to us the traces of a foregone and extinct civilization, while the records of ancient history still exist, marking a vast exodus from those regions which, by the raising of this mighty barrier, and the reflection of the gulf-stream westward to the shores of Europe, changed the smiling cornfields into hyperborean solitudes.

Europe, meanwhile, benefitting by the change, became freed from her icy bondage, which has left its tracings and markings over the whole western portion of it.

In Ireland, England, and Scotland, erratic boulders have been found—similarly also in Norway and Denmark—evidently transported on ice-fields, where no now moving ice-fields exist. The coasts of Norway and Sweden show, likewise, the grinding marks of passing floes of ice at a higher level than is reached at present by the sea, and to a depth of incision which the sea is in the present age unable to carve.

No upheaval of the Alps alone would be sufficient to account for all this, nor is it likely that portions of the crust of the earth, so little separated as are the Alps and the coast of Norway, should be, during the same epoch, moving in opposite directions, viz., subsiding in Switzerland while rising in Norway. Whereas, as I hope, I have sufficiently shown that the divergence or reflection backwards and westwards of the gulf stream, would satisfactorily account for it all.

If doubt remain in the minds of any, I would point to the climate of the Crimea, where, though placed in far more southern latitudes, our troops experienced much greater severity of winter than our English necessities had led us to provide against; or to the streets of New York, where, though situated in a latitude 11 degrees south of London, the sledging season commences earlier and lasts much longer and more severely than is experienced in any part of Great Britain.

It would be easy, yet needless, to multiply such examples.

It is with considerable diffidence that I venture to bar Professor Tyndall's passage in a path so peculiarly his own, but having ascertained, while attending a course of lectures on Light (delivered by him at the British Institution near three years ago), that he is fallible as myself, and that he suffers under some degree of colour-blindness, and is apt to mistake purple for blue, and orange for yellow, I feel less hesitation in thinking that he may likewise have fallen into another error.

I remain, Sir,
Yours faithfully,
CHAS. GUBBINS.

28, York-place, Portman-square.
Sept. 22, 1862.

THE STRAIGHT LINE *versus* THE WAVE LINE FOR VESSELS.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

SIR,—As I suppose the gentleman who signs himself "Nauticus" is the same to whom we used formerly to be indebted for many practical and valuable communications, I am rejoiced to find that he has again become one of your correspondents. I am not less pleased also to observe that he is not an advocate of the wave line theory, but prefers convex lines between the light and full load water levels for the bow of a vessel; for such lines with a very fine entrance differ very little theoretically, and perhaps not at all practically, from straight lines rounded off at three-fourths of their length from the stem, in order to form with the curvilinear remaining fourth a fair junction with the side.

But Nauticus says that "wave or concave lines below the water line are indispensable, and every practical naval architect knows why." It may be so, being an instance of that subordination of principles to circumstances to which I referred in my last, but theoretically they must be as wrong there as anywhere else. I suppose, however, that Nauticus refers to a filling up of the inward angle at the junction of the stem with the hull, in order to a proper fairing of the general form, of which the iron clipper sailing ship, the "Lord of the Isles," is a very good example. But such hollowness, slight, and localized in extent to little beyond the thickness of the stem, is very different from a concavity which runs far back into the hull, encroaching on the breadth of the vessel, and necessitating a more obtuse convexity farther aft than otherwise would be the case. It is not, as Mr. Young observes, every ship "whose bow has a hollow line which is a wave line ship." But even in regard to hollowness of this mitigated sort, might it not be advantageously avoided by allowing a greater retreating inclination to the stem, thus lessening the extent of dead wood, diminishing the dead weight upon the buoyancy of the bow, avoiding friction upon surfaces which are not utilized by inclosing capacity, and acquiring lines in the vertical and longitudinal sections of finer forms. I give my opinion, however, with diffidence, and with great deference to practical knowledge. Undoubtedly this large and nearly flat surface at the bow serves to retard lee way in a vessel, and it cannot, for reasons of construction, be allowed to project far in advance of the hull without receiving lateral support from it—hence the hollow curvilineal lines. But such surface cannot be indispensable, I presume, with steamers, which only hoist sail, I believe, with a very fair wind. I observe, too, that even the sailing yacht "America," of great celebrity, has a very retreating stem, and that the hollowness of her lines, instead of increasing, diminish with their depth below the load water line; but then her keel, by way of compensation, is very deep. If I had been more familiar with the technical terms, doubtless my meaning in the preceding remarks would have been more happily expressed.

Yours, &c.,
BENJAMIN CHEVERTON.

P.S.—In my last communication, in the last paragraph, there is an error in printing "destruction" instead of distinction.

PRINCIPLES OF AIR NAVIGATION.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

SIR,—Your correspondent, Mr. Quartermain, has a pleasant way of smoothing over a difficulty, but no amount of agreeable verbiage can put a gloss upon the fact, that whilst his theoretical phantasy leads him to the conclusion that a bird's wing equivalent to a certain plane surface, acting with a certain velocity upon the air, will meet with a resistance of 1¾ lbs. an appeal to the table of experiments by Dr. Hutton informs us, in a practical trustworthy manner, that with such data the the resistance will be only one-tenth of an ounce. Until he can convict those experiments of being enormously erroneous, it will be useless to continue the discussion, and the only observation which I shall make is, that he does not appear to have understood me in regard to the purport of the experiments I proposed for his consideration and instruction. It is the alleged elastic resistance to impart on air in free space that he must attend to, and not the same under confinement and restraint. Conclusions from one set of circumstances to the other will never do. I cannot part with him, however, without protesting most seriously against a perversion of my opinions, by a rather gross mistatement of them, in reference to my admission of the possibility that compression and elasticity in air may come into play even in a free space, and with very low velocities of the moving body—an admission considerately made in order to let him down gently, as it were. But I was careful to add, what Mr. Quartermain in his quotation chooses to omit, that such "fact is not sensible and can have practical effect only in the great velocities of militarp projectiles." It was only such suppression that could give a colouring of truth to his remark, that "Mr. Cheverton's faith in his own assertions surely begins to waver." It is a duty which disputants on both sides of a question owe to truth even more than to themselves, to discountenance everything which, whether intentionally or from carelessness, is unfair—a word of very mild expression to characterize, according to my notions of polemical ethics, a large portion of controversial tactics.

Yours, &c.,
BENJAMIN CHEVERTON.

"THE WAVE LEVEL"(?)

TO THE EDITOR OF "THE MECHANICS' MAGAZINE."

SIR,—I must beg leave to differ from "Nauticus" as to the wave line, as a water line for a ship's bow having been proved to be disadvantageous *when properly applied*. The line with which he has illustrated his letter, and which he *calls* a wave line would decidedly prove to be disadvantageous.

The truth, in most things, makes slow progress; errors are readily caught at and clung to, and to bring out the truth we must repeatedly strike the right nail on the head; and I must repeat Mr. Young's words, that all concave lines are not necessarily wave lines.

"Nauticus" says, "I know of no vessel having the wave line bow which is pre-eminently fast," &c. Did "Nauticus" never hear of the "America" yacht? and does not the Duke of Sutherland's yacht, referred to by him, steam from eleven and a-half to twelve miles an hour? Will "Nauticus" have the goodness to compare the number of square feet of canvass spread upon the mere jury masts of the latter vessel, with the relative quantity of canvass carried by vessels intended to sail fast, and after doing so call her a failure?

The advocates of the wave line system are quite alive to the importance of buoyancy, and part with much less of that essential quality than their opponents suppose. A vessel is none the worse for having her buoyancy brought aft.

There are two vessels pretty well known for speed, if "Nauticus" wishes to try his hand at designing fast vessels without wave lines, and can persuade any shipbuilder to adopt his design. The vessels I refer to are the "Lyons" and "Orleans," running between Newhaven and Dieppe, built by Mr. Scott Russell, on the wave line system. I am also quite willing to design a vessel which I will warrant to go twenty miles an hour. Will "Nauticus" do the same?

I am, Sir,
Your obedient servant,
T. Moy.

1, *Cliffords Inn*, 23*rd September*, 1862.

P.S.—The following extract is taken from the *Times* of Aug. 12, 1862, and shows, in a remarkable manner, the pernicious effects of the convex bow; referring to the "Pysche," paddle despatch gun-vessel:—

"The diagrams of the indicator and expansion cards were of unusually favourable character. At full speed the ship carried a tremendous wave under her bows, while at half-speed she carried one not a quarter the size. From these circumstances it was evident that as the driving power of the engines was increased from half to full speed, so the volume of water driven before her bows was also increased. If this fact be then taken as the cause of the slight difference in the ship's speed between half and full boiler-power, then the only conclusion arrived at is,—that, had the hull of the 'Psyche' been as perfect in form and capable of doing its work as is her machinery, the ship's speed at sea would equal the speed attained at the measured mile yesterday. As it is the 'Psych' may be looked upon as an eleven and three-quarter to twelve knot vessel at sea, taking the average of weather. The engines and boilers gave the greatest possible satisfaction by their working."

SAMUELSON'S IMPROVEMENTS IN SHIP-BUILDING.

The accompanying engravings illustrate a new method of building ships or vessels, which are to have armour plates applied to their sides, recently patented by Mr. A. Samuelson, of Cornhill.

Fig. 1 shows a horizontal section of a portion of a ship's or vessel's side, coated with armour plating, wherein the upright ribs or frames of the ship or vessel, consist of a series of acute angles, formed by rivetting plates to each other and to angle iron, and which are to be arranged at any desired distance apart, the outer plating or skin forming the base line of such angular ribs or frames. Fig. 2 shows another horizontal section of a portion of the side of a ship or vessel, also plated over with armour plating, in which figure the upright ribs or frames are rectangular; the sectional angular form of the ribs or upright frames may be varied; *b b* are the upright ribs or frames, which are each constructed of sheets of metal rivetted to each other, and where necessary to angle irons, or, if preferred, the sheets may be bent at their edges so as to form flanges, in place of using angle iron at the angles where the sheets are rivetted to each other, or to the plating of which the skin of the ship or vessel is composed. The plates which are to form the armour plating of a ship or vessel are each turned up at their ends so as to form internal flanges; and where the ribs or upright frames are formed to an acute angle in section, the metal of the in-

SAMUELSON'S IMPROVEMENTS IN SHIP-BUILDING.

FIG. 1

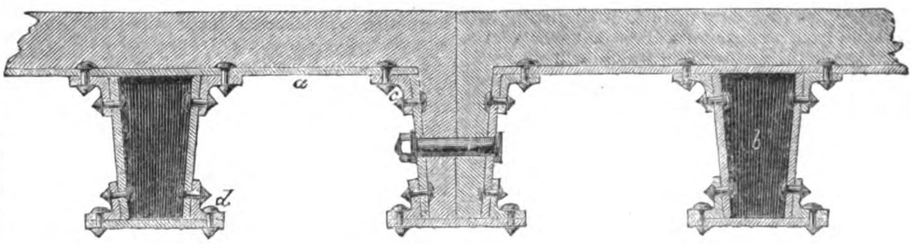

FIG. 2

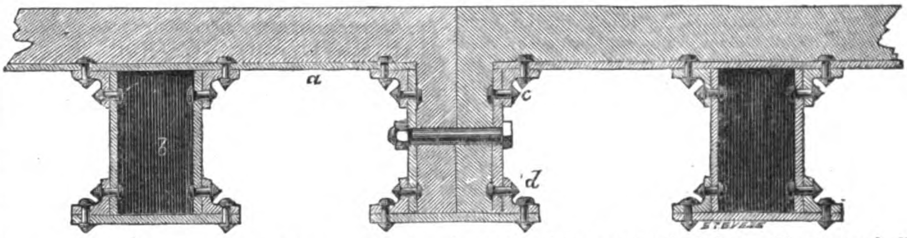

terior flanges of the armour plates are bevilled, so that when the flanges at the ends of two contiguous armour plates come together within a rib or upright frame, they will fill the interior of such rib or upright frame, and the plates of such rib, as well as the flanges of the armour plates, may then be securely fixed by through bolts, which it is preferred should be screw bolts with nuts. By these means the armour plates will contribute great additional strength to the construction of the body of a ship, in consequence of the flanges at the ends of the armour plates entering the hollow ribs or upright framings of the ship or vessel, and by reason of their being fastened thereto, and to each other, whilst the use of bolts through the armour plates is rendered unnecessary. The outer skin of such vessels may be made by plating according to any of the systems of plating heretofore practised, but it is preferred that the edges of the sheets of the outer plating or skin should not lap where they are rivetted together, but that their edges should butt together and be rivetted to butt pieces, as is well understood; this however is not essential. *a* is the plating forming the outer skin of the vessel, this skin or outer plating is shewn to intervene between the back of the armour plating and the angular ribs or frames; this, however, is not essential, as the ribs or upright frames may, when desired, come directly against the back of the armour plating, in which case the skin or outer plating would be used between the ribs or upright frames; or where the ribs or upright frames are triangular in their horizontal section, they may come close together, forming a uniform zig-zag framing, constructed of plates and angle iron rivetted together; *b b* are the angular hollow ribs or upright frames which are produced by rivetting plates to each other, and to angle iron *c c* and *d d* where desired.

THE FEDERAL IRON-PLATED NAVY.

The *New York Evening Post* gives the following account of the iron-plated vessels now being built in the ports in the United States:—

"We published a short time ago an account of iron-clads building, and need only recapitulate. We have given elsewhere in this article a full account of the iron-clads in the Western waters. The other iron-clads afloat are the "Monitor," the "Galena," the "Naugatuck," and the "Ironsides." The latter is just completed at Philadelphia, and sailed from that place August 20. Her destination is kept secret. By her contract she was to have been ready July 15. Detailed descriptions of these vessels have been published. The "Monitor" has, as it were, two hulls, the upper one mailed with iron 6 inches thick, and defending the lower one, which is light, composed of three-quarter-inch iron. The upper hull is 174 feet long, and 41 feet wide. The vessel draws 9 feet; she has in the centre of her deck a revolving turret, 9 feet high and of 20 feet internal diameter, composed of iron 9 inches thick. Her armament consists of two 11-inch Dahlgren guns, fired from inside the turret. These will be replaced by larger guns. She was built at Green-point in one hundred days. The "Galena" was built at Mystic. She is not of the "Monitor" type. Her armour is 3 inches and a-half thick; she is 208 feet long, 36 feet broad, 12 feet and a half depth of hold, 1,000 tons burthen. She carries 6 guns, but is pierced for 18. The "Naugatuck" is an iron-clad canal-boat propeller, 101 ft. long, 32 ft. wide, and 9 ft. depth of hold; she has compartments by which she can be filled with water and sunk to the water's edge. The "Ironsides" is 232 feet long, 57½ feet wide, 17 feet deep, and draws 15 feet of water. She is 350 tons burden. The frigate "Roanoke" is iron-plated at the Brooklyn Navy-yard. She will have three great turrets and a powerful ram. She will be ready in about five weeks. Nine Ericsson vessels are building, which are almost exactly alike—three at Green-point, two at Boston, one at Wellington (Delaware), two at Chester (Pensylvania), and one at Jersey city. Their length will be about 200 feet, breadth 45 feet, depth 12 feet, diameter of turret 21 feet, thickness 11 inches. The keel of another Monitor has been laid at Greenpoint, different from the others. She will be 226 feet long, 48 feet wide, 13 feet deep, and will have two turrets. Reany, Son and Co., of Chester, Pennsylvania, have a contract for the construction of an iron gunboat 236 feet long, 35 feet wide, and 12 feet deep, which will be the only iron side-wheel steamer in the world. Besides these two Monitors are building at the same place. The Navy department has advertised for proposals for side-wheeled steamers of iron and wood combined. It is proposed to plate a number of them. In consequence of the singularity of this proposal several officers have been sent here by the British Admiralty to report what we consider their superior advantages. A novel vessel is near completion at the Dry Dock Iron Works, built by Charles W. Whitney. We gave a full description of her some days ago. Another vessel, on the plan of the Monitor, is building at Boston, to be 240 feet long and 1,300 tons burden. A vessel 250 feet long is under way at Jersey city for California. An iron-clad vessel will be immediately commenced at the Brooklyn Navy-yard, to be 200 feet long. The keel of another, to be 250 feet long, was laid a short time ago at the Delamater Iron Works. Captain Ericsson has recently made a contract with the Government for two immense iron-plated ships of great speed and strength. One will be

320 feet, and the other 340 feet in length. The turret will be strong enough to stand the shock of 425-pounders. Mr. Webb, of this city, has contracted to build an iron ram of immense size, to carry two revolving turrets. The plating will be solid iron, and there will be a cover of 12-inch iron on the bow, from which will protrude a solid projecting iron ram. A submarine iron propeller, built at Nearthenvy's, Philadelphia, for the Government, was recently launched. It is 65 feet long, 6 feet deep, and 5 feet wide. It is sharp at each end, and perfectly round. There is an opening for the entrance of the crew at one end. This can be closed, and the boat then sunk and moved in any direction by means of paddles, of which there are twelve on each side. There is a hole in the bottom, through which a man may pass in submarine armour. We have, therefore, the "Ironsides," "Roanoke," "Monitor," "Galena," "Naugatuck," one submarine iron propeller, and eleven iron gun-boats on the Western rivers afloat, and 12 Monitors and 10 gunboats for the Ohio river, four Mississippi gunboats, one iron-clad, at the Navy-yard, one at Boston, one at Greenpoint, one at Dry-dock, one at the Delamater Works, and one large ram building. It is stated that Mr. Ericsson has a contract for still another, which would bring the number positively built or building to fifty."

NEW ICE MACHINE.

ALL the means hitherto employed for the manufacture of ice commercially have left much to desire; some with regard to the character of the ice obtained, others with respect to the construction of the machines or the fittings; others also on account of the quality of the ice made, which is sometimes of too small density, rendering the preservation of it difficult, or else of such an aspect and odour as to make its use almost impossible.

A new inventor has just discovered and patented a system which has no longer the faults, the inconvenience and the danger of others, but offers, on the contrary, immense advantages in its construction, and in the quantity of ice it produces. The inventor is M. Lespine, who has succeeded, after many years of persevering labour, in furnishing for use machines of a rare perfection, of a simple and easy construction, always certain and regular in their action, liable to no explosion or derangement, and producing much more ice than any other system in use up to this time. The price of a machine capable of producing every hour—

20 kilogrammes of ice is	4,000	francs.
40 ,, ,,	8,000	,,
60 ,, ,,	12,000	,,
80 ,, ,,	16,000	,,
100 ,, ,,	18,000	,,

The profit (at Paris) on the rough ice is guaranteed by M. Lespine at three centimes the kilogramme. The ingenious construction of these machines offers, in addition to the advantages enumerated above, that of answering all the various purposes for which cold is required, without introducing any modification into its machinery.

The production of cold graduated at pleasure between zero and 30 degrees centigrade below zero, adapts these machines for scientific as well as commercial purposes. The different ways in which cold is used may be classed into three divisions: the 1st comprising private uses and the daily necessities of domestic life; the 2nd the preservation of public health, the salubrity and the welfare of the million; the 3rd including the various and different branches of industry.

The following summary gives fuller details of the varied applications of ice and the apparatus of M. Lespine:—

For private purposes and the daily requirements of domestic life:—

1. The production of rough ice at will, soft or hard, transparent or opaque.
2. The manufacture of sherbet and comestible ice in masses, more or less dense, iced wines, &c.
3. The preservation of meat, butter, cream, pulse, and alimentary substances in general.
4. The cooling of beverages of all kinds.

For public health and salubrity, by lowering the temperature in crowded localities, &c.:—

1. As in theatres, factories, work-shops, hospitals, ambulances and dissecting-rooms, slaughter-houses, &c.
2. By employing ice or cold in all its forms, within and without buildings, as a remedy for, and preventive of, many epidemic and endemic diseases resulting from intense heat.
3. The separation of salt from sea water, so as to render it drinkable on board, or to promote congelation.
4. Cooling the cabins of passengers and officers in ships, so as to enable them to defy the heat in the tropics in long voyages, &c.

For scientific and industrial purposes:—

1. Various preparations, and the concentration of a great number of chemical products.
2. The manufacture of essential oils, certain colours, sea salt, sugars, &c.
3. Cooling the wort of beers, and, by consequence, improving the make of beer, especially in warm countries.
4. Concentration of alcohols, spirits, and wines, and the improvement of wines in middling years, so as to admit of their keeping when shipped, &c.

M. Lespine adds to his machine a particular method of action of extreme simplicity of detail, by which blocks of ice may be formed of considerable weight with the smallest possible volume, thus rendering the preservation and transport of the ice more easy.

Gossip.

Experiments were made last week on the Tyne, for the purpose of ascertaining the capabilities of a screw steam hopper-barge, constructed by Messrs. Richardson and Co., Low Walker (the engines by Messrs. R. and W. Hawthorn), from the designs and specifications of Mr. Ure, the engineer of the River Tyne Commission. The object of a hopper-barge is to carry out to sea the sand dredged from the bed of the river, and then to let it fall through the bottom into deep waters, where there is no chance of its being washed backed again into the river. The old arrangement was to have these barges towed, one or two at a time, by ordinary tug-boats; and the object which Mr. Ure had in view in getting the present steam hopper constructed was to reduce the first cost, and the cost of working, by having the cargo of sand and the propelling power in one vessel. This has been most satisfactorily accomplished—as the vessel took out 300 tons of sand from the ballast-ground, 4 miles from the large dredger, in Shields harbour, and returned, after discharging her load, in one hour—her speed, when light, being 9½ statute miles per hour, and when loaded about 8¼. She then took a loaded hopper-barge of the ordinary construction in tow, being loaded at the same time herself, and tried her speed against one of the most powerful of the commissioners' tugs, towing one ordinary hopper-barge loaded; and under these conditions she had a decided though slight advantage in speed; that is to say, she carried 600 tons to sea in the same time as, under the old system, a load of 300 tons was carried; and, when regularly working with a barge to tow, she could load, take out to sea, and return once in every two hours and a-half; thus getting rid of 2,400 tons in 10 hours. Everything about the vessel worked satisfactorily.

A new joint-stock company has recently been formed in London, called the "St. David's Gold Mining Company" (limited), the object of which is to purchase and work an extensive grant of land for gold, silver, and copper, in the parish of Llanaber, Merionethshire, North Wales. The land proposed to be worked adjoins the Vigra and Clogau Gold Mine, specimens of the gold from which are to be seen in class 383 of the British Mineral Department of the Great International Exhibition, and the yield of which is stated to be unusually large.

A scientific balloon ascent for meteorological investigations is shortly to be made in Prussia, under the direction of the Berlin Academy, on the plan of the successful ascents of Mr. Glashier, which have excited very great interest amongst learned societies abroad. A new balloon for military purposes, which can be made to ascend or descend by a peculiar apparatus attached to the car, is stated to have been made by the French aeronaut, M. Goddard.

On the Scheldt, near Antwerp, experiments have been made with a river boat provided with a new propelling power, which has been recently discovered. The boat has neither paddle-wheels nor screw. In the middle of it, however, is a cone-shaped kettle into which the water is pumped up, and from which it is driven out with great force into the river through two curved boxes on the side of the boat, by which means the vessel is propelled forward with great swiftness. By simple machinery the arrangements of the boxes can be so altered that the boat can be turned immediately and steered in any direction. The experiments made with this boat, which is intended to ply between Luik and Seraing, have far exceeded expectation, and will perhaps cause a revolution in the means of propulsion. The new system, which has been discovered by a German, one Mr. Seiber, can be very well applied to large vessels.

The patented ship's rudder of Capt. Warren, R.N., having been experimented upon satisfactorily, by Capt. Broadhead, of Portsmouth, it is stated that the Lords of the Admiralty intend to more fully test the value of the invention, by putting it to the iron ship, Sharpshooter.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

THE Abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following Table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved, and combined with all the advantages of a division into classes. It should be understood that these abridgements are prepared exclusively for this Magazine from official copies supplied by the Government, and are therefore the property of the Proprietors of this Magazine. Other Papers are hereby warned not to produce them without an acknowledgement:—

600. T. BOSTOCK. *Improvements in the manufacture of boots and shoes.* Dated March 5, 1862.

Here the patentee uses a block, perforated throughout its entire thickness with a hole of the size and shape of the sole, heel, or other part of the bottom of the boot or shoe, and he also employs in connection therewith two dies, male and female, corresponding in form on their adjacent upper and under surfaces with the convex surface of the bottom of the last, and accurately fitting at their edges within the perforation of the block. The piece of leather to be operated upon is cut out to the required shape and size for forming the sole, heel, or other part of the boot or shoe, the edge being bevelled, in order that the surface of the leather which receives the convex die shall be larger than the other surface. The piece of leather is then placed between the two dies and within the perforated block; and pressure being thus brought to bear upon the block, by means of a screw or weighted lever, the leather receives the required bedding to the last, and solidifying both of the surfaces and the edges at one and the same time. *Patent completed.*

601. E. PARTINGTON. *Certain improvements in the method of cleansing and preparing rags or other materials used in the manufacture of paper, and in machinery or apparatus connected therewith.* Dated March 5, 1862.

The machinery for effecting the washing and cleansing of the material consists in a chamber having its interior surface furnished with projections, teeth, or tearing points, and being spirally arranged. Within this chamber a cylinder revolves, having projections upon its periphery, also spirally arranged, and passing between the others in its revolutions; so that, by means of the propelling power of the spirally arranged teeth, the dirty material is passed through the machine in one direction, and subjected to their tearing action during its progress, the course of the washing water through the chamber being opposite, so as to meet the material in a pure state, cleanse it, and pass off through the strainer (to retain the fibrous material) when rendered unclean. When the material has passed through the machine, and is sufficiently purified, a large pronged fork is thrust into it from an opening in the side of the machine by a crank, which removes as much as it can contain, and deposits it in a receptacle provided for the purpose. *Patent completed.*

602. F. W. GISBORNE. *Improvements in the mode of indicating numerals or letters in railway tickets and other articles by peculiar devices cut therein, and in apparatus for effecting the same.* Dated March 5, 1862.

This invention is not described apart from the drawings. *Patent completed.*

603. W. E. NEWTON. *An improved process and apparatus for reducing wood, straw, and other vegetable substances to pulp, for the manufacture of paper.* (A communication.) Dated March 5, 1862.

This consists in disintegrating wood and other fibre-yielding vegetable substances for the production of paper stock, by subjecting such substances to the mechanical operation of breaking, beating, or grinding, while it is immersed in and under the chemical influences of highly-heated water, and under the pressure due to such high temperature. *Patent completed.*

604. J. BARKER. *Improvements in, and means and apparatus for, casting drums, pullies, gear, and other wheels and bushes or keys for the same.* Dated March 6, 1862.

This relates to those drum pulleys, gear, and other wheels which are fixed on shafting by conical bushes or cylindrical keys; and the object of the invention is to economize labour and reduce the cost of fitting up or of manufacturing shafting and gearing. *Patent completed.*

605. G. LAWRENCE. *Improvements in the manufacture of flesh-gloves and flesh-straps.* Dated March 6, 1862.

This consists in so manufacturing flesh-gloves and flesh-straps, that the same instruments may be used at different times, either as flesh-gloves or flesh-straps. For these purposes flesh-gloves are made in a manner very similar to that now commonly practised, but with a strap at one end of each glove; and the other end of such flesh-glove is formed so as to be readily joined or connected with its fellow-glove by buttons or otherwise; thus forming a flesh-strap. *Patent abandoned.*

606. T. HACK aud A. E. CARTER. *Improvements in screw-cocks.* Dated March 6, 1862.

Here, to avoid the use of the ordinary packing, the patentees cause the valve-spindle to terminate within the valve-case with a head suitable to receive a key. A corresponding key is placed immediately over the head, and the stem of this key, which is cylindrical, passes out through a corresponding hole in the cover of the valve case, the stem of the key fitting the hole loosely. Beneath this hole a cylindrical chamber, somewhat larger in diameter than the stem of the key, is formed in the cover of the valve case; the lower part of the key is enlarged to fit this hole, and between the top of the enlargement on the key, and the top of the cylindrical chamber, a ring of brass is placed, which is fitted accurately, both to the surfaces above and below it. The fluid within the valve case, being in contact with the bottom of the key, presses it upwards, and keeps the top of the enlarged portion of the key in close and fluid-tight contact with the brass ring; and this latter is, by the same means, kept in fluid-tight contact with the top of the chamber in the cover of the valve case; thus the escape of fluid by the passage by which the key passes out is prevented. In order to steady the screw-spindle, and to keep it truly in its place, its upper end is passed through a guide ring, screwed into the bottom of the chamber in the valve case. This ring also serves to take the upward thrust of the spindle, on which there is an enlargement immediately below the ring. The upper surface of the ring also serves to support a spring, which is employed to sustain the key should the pressure of the fluid at any time be insufficient for the purpose. *Patent completed.*

607. J. G. SHIPLEY. *Improvements in bridle-heads, reins, and bits.* Dated March 7, 1862.

The improvements in bridle-heads and reins consist in substituting studs and holes for buckles or sewing, as hitherto practised. The improvements in bits consist in making each of the checks thereof divided, or in two or more parts or pieces, for the purpose of adapting thereto mouth-pieces of different forms. Also in forming each of the solid cheeks of bits with a piece of metal having a screw formed thereon to receive mouth-pieces of different forms, the ends of the said mouth-pieces having screwed holes formed therein for connecting the same to the cheeks of the bit. *Patent completed.*

608. M. B. NEWTON. *Improvements in the manufacture and construction of junction and other drain pipes in clay or other plastic materials.* Dated March 7, 1862.

The documents relating to this invention are with the law officers under objection, and cannot at present be seen.

609. T. FARRIMOND. *An improved safety cage for mines.* Dated March 7, 1862.

Here the inventor places two horizontal shafts through the cage near the centre, and fixes on each end of the shafts eccentric levers having teeth at their extremities. The said shafts are worked by a coupling and chain connected with the main rope, and one or more springs are attached to the coupling for the purpose of turning the shafts and bringing the toothed ends of the levers forcibly in contact with the guide rods or ropes whenever the main rope breaks, and thereby hold the cage and prevent accident. *Patent abandoned.*

610. J. REVELL. *Improvements in securing the rails of railways and tramways to the chairs.* Dated March 7, 1862.

Here the inventor secures the rail to the chair by means of an improved key wedge or packing. On that side of the key next to the rail he makes a sunk or hollow bed to receive a strong, firm packing, made of hard wood or lead. The packing fits tightly in the hollow bed, and projects a little from the surface of the key, pressing firmly against the rails. On the side of the key pressing against the chair, the upper part may be in contact, or quite free, without any packing whatever, but in the lower part he sinks a rebate or groove, and in connection with it a sunken bed of dove-tail or other suitable shape, into which he places a locking or tying key, previous to the main key being driven between the rails and chair. After the main key has received the packing in the hollow or sunken bed, and also the tying or locking key, it may then be driven into its place in the same manner as the ordinary wedges are now driven; then he turns down or bends each end of the locking keys against the chair in order to keep it firmly in its ace. *Patent abandoned.*

611. J. CARPENDALE and T. MIDDLETON. *Improvements in means of producing raised chasing on copper, silver, and Britannia metal, by the application of pressure.* Dated March 7, 1862.

This invention admits of, and consists in, means for the pressure being determined and applied on an extended scale by the adjustment of the machines. *Patent abandoned.*

612. J. FOWLER, jun., D. GREIG, and R. NODDINGS. *Improvements in apparatus for cultivating or tilling land.* Dated March 7, 1862.

This consists in placing the axis or fulcrum of the balance frame below the axis of the carrying wheels. For this purpose the patentees employ by preference an axle, which they attach to the balance frame at two points across it, and at each end of this axle is a standard or slide bar on which the short axle of the carrying wheel is placed; thus it will be seen that the weight of the frame resting on its fulcrum below the axis of the carrying wheels, causes the standards or slide bars to assume at all times a vertical or neatly vertical position, and the short axles of the wheels, being attached to and centering on the standards, the locking of the wheels does not affect the general level of the balance frame. In the construction of rotary cultivating implements to be worked by steam power, they employ one or more plain cylinders or axles armed with prongs, which by their weight penetrate into the land, and this improvement consists in causing the main cylinder or axle to drive another or other similar axle or axles, also armed with prongs, at a higher velocity than that at which itself rotates; thus the main cylinder breaks up the land roughly, and the second, being driven by it at greater speed, reduces the clods to a finer and better condition. Two such axles with prongs form a cultivator to be turned at the headland, but four or more can be used with advantage when mounted on a balance frame. In constructing winding apparatus, where drums mounted on horizontal axles are employed, they sometimes arrange the boiler, engines, and windlasses so that they can turn partially round on their carriage frames, so as to adjust the plane of the drum to the line of draught. This may be accomplished by a turn plate or table, arranged so that the machinery and carriage frame can readily be fixed in such a position that the hauling rope may be led on at an angle to the carriage or carriage frame. Other similar arrangements may be made. *Patent completed.*

613. T. and W. BATT, and J. WILKINS. *Improvements in the manufacture of warp fabrics in warp machines.* Dated March 7, 1862.

This consists in a peculiar mode of arranging and lapping the warp threads of warp machinery, whereby very novel warp fabrics are produced, one surface consisting of raised pyramids, and the reverse side of corresponding cavities. For this purpose the warp threads are caused to lap, so that the fabric is divided longitudinally and transversely, so that the fabric may be said to consist of a series of square sections, which, by reason of the fabric being elastic, will, when the fabric is free, shrink, and the several sections form themselves into pyramids. The way in which the warp threads are lapped on the needles to produce these effects may be varied; the number of threads used, the size and distance apart of the pyramids may also be varied. The effects produced may also be heightened by using different coloured warp threads, and by using extra or ornamenting threads, particularly at the apex of each or some of the pyramids. *Patent completed.*

614. R. WRIGHT. *Improvements in heating and clarifying saccharine fluids.* Dated March 7, 1862.

This consists in carrying on the heating and clarifying process in vessels or apparatus, such as are described in the specification of a former patent granted to the present patentee, dated 6th September, 1860. (No. 2,153) for evaporating saccharine fluids in the manufacture and refining of sugar; but when heating and clarifying saccharine fluids according to the present invention, the revolving discs or surfaces described in such former specification are not used, the clarifying process not requiring evaporation or motion of the fluid, as when manufacturing or refining sugar, as described in such former specification. By these means of carrying on the process of heating and clarifying saccharine fluids, the bottom of the pan or vessel containing the saccharine fluid is treated by the vapour of boiling water, which is in a vessel below; at the same time the water in this vessel is prevented from coming in contact with the bottom of the pan or vessel containing the saccharine fluid, and is also prevented from using in temperature above 212 deg. Faht. by reason of the vessel containing it being constantly open to the atmosphere. *Patent completed.*

615. J. BROOK. *Improvements in ladies' dresses.* Dated March 7, 1862.

Provisional Protection has not been allowed for this invention.

616. R. RESTALL. *Improvements in apparatuses for connecting and disconnecting carriages and engines on railways, as also signal lines between guard and driver.* Dated March 7, 1862.

By means of this invention carriages may be connected and disconnected whether at rest or in motion. First, the invention consists in attaching to the engine or to the tender, or to any carriage, waggon, van, or truck a stirrup, which is hinged to a plate, a perforated rod, or wormed bar, which passes through the frame, and is connected to an ordinary draw spring, or not, as may be needed. Or the plate may be fixed, or may be connected to a tightening apparatus. The stirrup has fitted to it, and depending from it, a weighted U-shaped bar, while a double similarly-shaped bar is connected by loops to the upper surface of the stirrup; this latter bar has attached to it a cord, strap, or chain, which is carried to some part within reach of the driver, guard, or attendant, and at the side of the U-shaped bar is placed a flat bar, with a sliding loop for connecting and disconnecting a signal between guard and driver; the carriage to come next to that carrying the stirrup is fitted with an ordinary draw hook, or to one or other of the connecting hooks described with reference to the drawings.

To connect the coupling side chains, it is necessary an attendant should hook them on, but there is no necessity for him to enter between the rails, as the hooking on should be performed outside the rails on each side. In order to tighten up the coupling, whether the stirrup or any other coupling, the patentee connects to the plate which carries the stirrup, a rack, which passes through the front or back frame, as the case may be. This rack is geared into by a pinion, which is worked by a handle either directly or through a worm and wheels, or a wheel working on a worm, and the connections are so made as to admit of the stirrup bar being moved outwards or inwards as may be required. The invention also consists of a connecting and disconnecting apparatus, formed of a spiral spring draw bolt, which is raised to release a coupling, or lowered to effect and retain the coupling. The invention also consists in forming a looped hook at the end of each of the side chains, and in carrying a chain, cord, or band within reach of the driver or attendant, so that when required, by pulling on a cord, the chains can be released. He employs a separate looped hook for each side chain. He sometimes hinges on to a plate bolted to the engine, tender, or carriage a weighted looped hook, to receive one end of the side chain or other coupling, and he attaches a line, cord, or chain to the hook in such manner that, on the hook being pulled up, the chain will be liberated. *Patent completed.*

617. T. H. WOOD. *Improvements in apparatus employed in the manufacture of Artificial Fuel.* Dated March 7, 1862.

This invention was described and illustrated at page 163 of the present volume of this journal. *Patent completed.*

618. H. B. COATHUPE. *Improvements in the manufacture of clips, hooks, and other such like fastenings.* Dated March 7, 1862.

Here the patentee proposes cutting or stamping the hooks or clips out of sheet metal, in the form of the letters H. I. Y. or X., and folding such Y pieces when separated from each other (or a series of such pieces in combination), by which one end is formed into a spike or nail, whilst the other can be used to clip or hold the tube, and either to encircle the tube, or only partly so, as is now done by what is known as the gas hook. The right and left hand arms of the X pieces are intended to be turned in two opposite directions, thus presenting a forked piece, to be driven or fastened to wood, or any other material, and another to hold the tube or pipe. *Patent abandoned.*

619. A. W. WILLIAMSON. *Improvements in apparatus for generating steam, or for generating and superheating steam.* Dated March 8, 1862.

Here the patentee uses a number of tubes of moderate diameters, either made by drawing or welding, when they have to stand a very great internal pressure, or formed of rivetted plates, when used for lower pressures, which tubes will afford considerable strength with only a moderate thickness of metal. Each of these tubes is made to act as a steam boiler, or combined steam boiler and superheater, being so arranged in a slanting position, that the water contained in the same is at one end, and the steam at the other, or chiefly so. These boilers are connected together at their lower ends by tubes of greater or less diameter, or size, through which they are supplied with water. In order to give stability, these boilers are firmly fixed at the lower end, and are only so far supported or confined at the upper end, to prevent inconvenient movement, but not to prevent or impede their lengthening, or expansion. The rigid connection at their lower end is effected by a direct connection to a foundation, without putting any strain on the connecting pipes supplying the water; or the boilers are firmly attached to connecting pipes, strong enough to hold them securely to the foundation. The steam is taken from the upper end of each of these boilers by a curved pipe of copper, or thin iron, sufficiently long to admit of its yielding, without injurious strain, to the expansion of the boiler. These small steam pipes open into larger ones, which convey the steam to wherever required. The furnace is so arranged that the flames first strike against the lower part of the boilers containing the water, and pass through spaces left between them, either directly to the flue or uptake, or else to the upper part containing the steam, which, by this means, becomes superheated. The connecting pipes supplying the water are so arranged as to be protected from the heat of the furnace. *Patent completed.*

620. H. FLETCHER. *An improved clip for securing the steel or other expanders of crinolines to the suspenders thereof.* Dated March 8, 1862.

This consists in forming a clip with slits or holes therein, through which are passed the suspenders of the crinoline, and likewise the steel or other expanders, or the expanders may be otherwise connected thereto. By these means the clip cannot possibly become detached therefrom accidentally. *Patent abandoned.*

621. G. EDMONSON. *Improvements in washing machines.* Dated March 8, 1862.

This consists in improvements upon a former patent granted to the present patentee, dated 1st of April, 1861 (No. 798). In that machine he used a single chain for giving motion to the feeding and delivery rollers, and a number of guide rollers. He now substitutes two chains for the single chain, and drives the feed and delivery rollers independently of each other by separate chain pinions, which arrangement enables the stretching pulleys to be dispensed with, and saves expense in the fitting. He uses spiral springs for exerting the required pressure upon the delivery rollers, and also dispenses with the guide rollers, unless the machine is of such dimensions as to require them. *Patent completed.*

622. A. BLAIR. *Improvements in rotatory engines.* Dated March 8, 1862.

This invention is not described apart from the drawings. *Patent completed,*

623. W. PATERSON, W. A. SANDERSON, and R. SANDERSON, jun. *Improvements in finishing woven fabrics.* Dated March 8, 1862.

The patentees claim the method of finishing woven fabrics, and producing the kind of pile thereon, by floating certain of the warp or weft threads over the surface of the same, and then breaking through such floated threads by cards or strong

tearles, and raising such broken threads into a pile, as described. *Patent completed.*

624. S. S. Bromhead. *Improvements in the construction of boxes or receptacles for coals.* Dated March 8, 1862.

These boxes are formed of metal or wood, or of other material, an iron grating or a plate or diaphragm composed of wirework or of perforated material being placed therein, either entirely or partially across the area of the interior of the box. Such grating, plate, or diaphragm may be placed either in a horizontal or slanting position, and has the effect of sifting or screening the coal, or of regulating the pressure thereof upon the lower chamber or compartment of the box. In order to provide for and facilitate the removal of the dust or small coal separated and collected by the agency of the said grating, plate, or diaphragm, a mouth-piece or aperture, with or without a removable cover, as may be desired, is provided at the lower part of the box, such mouth-piece or aperture admitting of the introduction of a slice, scoop, or shovel. *Patent completed.*

625. J. Platt and W. Richardson. *Improvements in machinery or apparatus for cleaning from seeds and for carding cotton, such improvements in carding being also applicable to other fibrous materials.* Dated March 8, 1862.

This relates to that machine for cleaning cotton from seeds known as the Mocarthy gin. In such arrangements a reciprocating blade is used, working in conjunction with a fixed blade and roller. According to this invention the patentees use two reciprocating blades, coming into action alternately. *Patent completed.*

626. J. Deane, jun. *Improvements in revolving fire-arms.* Dated March 8, 1862.

This invention was described and illustrated at page 178 of the present volume of this journal. *Patent completed.*

627. W. N. Wilkins. *Improvements in the manufacture of pigments for oil and water colours.* Dated March 8, 1862.

The object of this invention is the manufacture of white pigments to be mixed with oil and water, as hereafter explained, to supersede white lead and other pigments now used by painters, decorators, artists and others, in laying on colour on pictures, wood, stone, and other materials requiring to be painted. The inventor manufactures his white pigment for oil painting of equal parts of white oxide of zinc and plaster of Paris, chalk, or any white aluminous earth, such as kaolin and pipeclay. He does not limit himself to the proportions stated, as a third, or even less, of the white oxide of zinc with plaster of Paris will give a brighter result, though more difficult to work with the brush. He manufactures the white pigment for water colour by mixing plaster of Paris with size or glue, in proportions according to the consistence that may be required. For grinding and mixing the pigments the machinery and apparatus are the same as those now used for grinding and mixing pigments and colours. *Patent abandoned.*

628. P. J. Guyet. *Improvements in water meters.* Dated March 8, 1862.

This invention is not described apart from the drawings. *Patent completed.*

629. S. Grick. *An improvement or improvements in propellers for propelling ships and boats and other vessels.* Dated March 8, 1862.

Here, on the end of a shaft, similar to that ordinarily used for screw propellers, to which shaft a rotatory motion is given by steam or other power, the inventor fixes a circular plate or disc, to which a hemisphere or dome is secured, by screws or otherwise, the base of the hemisphere being in contact with the said plate. On the exterior or convex surface of the hemisphere, a series of vanes or blades is fixed. The said vanes or blades are so situated on the dome, that their narrow ends meet at the summit of the said dome. The blades extend from the summit of the drum to the base thereof, the course of each blade being oblique, that is inclined to the axis of the dome. The said blades are made deeper as they approach the base of the dome, and the planes of the blades are inclined to the surface of the dome. The base of each blade may be secured to a flange at the base of the dome. *Patent abandoned.*

630. W. Clark. *Improvements in brims and peaks of hats, caps, and other coverings for the head.* (A communication.) Dated March 8, 1862.

This relates to shades or peaks for caps and other like coverings for the head, which is applicable also to the brims of cloth, silk, beaver, straw, and other hats; and consists in fitting the hat or cap peak, or brim, to receive a miniature looking-glass, comb, pencil, &c. *Patent abandoned.*

631. W. Palmer. *Improvements in the manufacture of candles.* Dated March 8, 1862.

This consists in combining tallow, cocoa-nut oil, or palm oil, or products obtained from these, with those fluid mineral oils which filter or run, or are obtained by pressure from American or rock oil, or rangon tar, or earth, or similar natural mineral oils, which retain their fluidity at the ordinary temperatures of this country. It is preferred that these oils should be in a purified state when used. *Patent completed.*

632. J. Fleming. *Improvements in machinery for pressing cotton.* (A communication.) Dated March 8, 1862.

Here a mechanical or lever press is combined with hydraulic apparatus, so that the lever press performs with speed the first or earlier parts of the dressing process, and the hydraulic pressure comes into action when the lever press ceases to act, the lever press being so arranged that at this time it will be in the most favourable position for resisting the pressure exerted by the hydraulic apparatus. *Patent abandoned.*

633. F. W. Gisborne and H. Wickens. *Improvements in the means of indicating the pressure of fire-damp or choke-damp in mines, and of dispersing fire-damp, and also of telegraphing in mines.* Dated March 8, 1862.

The fire-damp or carburetted hydrogen gas which is generated in a coal mine is of less weight or specific gravity than the atmospheric air, and the choke-damp or carbonic acid gas in a mine is of greater weight or specific gravity than the atmospheric air, and this invention consists in the use, in combination with suitable apparatus, of those relatively lesser or greater weights to connect an electric circuit, and thereby cause the required indications or signals to be given. *Patent abandoned.*

634. L. R. Sykes. *Improvements in gloves.* Dated March 8, 1862.

This relates to a novel method of applying purses or money receptacles to gloves, either for ladies' or gentlemen's wear. The inventor proposes stitching a piece of kid or other suitable elastic material of convenient shape or form on the outside of the palm of the glove, one end of which is to be left open and provided with an elastic fastening, or a suitable tongue or metal fastening. There are other modifications. *Patent abandoned.*

635. F. R. Newton and H. Codd. *An apparatus for indicating and measuring the flow of liquids.* Dated March 8, 1862.

This consists in a method of indicating and measuring the withdrawal of liquids from casks or other vessels by means of apparatus in connection with, and operated by, the ordinary beer engines or other means. The apparatus consists of two plates of metal, bolted or pinned together, leaving a space between them for the arrangement of a series of cogged wheels and pinions, similar to the manner of clockwork, the one working the other, and actuating a series of pointers, hands, or indicators, travelling on centres around the faces of dials in front of the apparatus. The dials are provided with numbers, the front dial indicating from units upwards, the second indicating tens, and the third hundreds; or the first pence, the second shillings, and the third pounds, according to the number of teeth in the various wheels and pinions. *Patent completed.*

636. J. J. H. Gebhardt. *An improved fastening for albums and other books, bags, reticules, and other articles.* (A communication.) Dated March 8, 1862.

This consists of a sliding or travelling piece fastener, in which are spiral springs acting in connection with certain studs or stops, and a knob or finger-piece. The travelling piece carries a hook, catch, or holding part, intended, when the fastening is closed, to engage in an eye, wire, staple, recess, or equivalent therefor. *Patent abandoned.*

637. M. A. F. Mennons. *Certain improvements in breech-loading fire-arms.* (A communication.) Dated March 10, 1862.

This invention is not described apart from the drawings. *Patent abandoned.*

638. J. Duncan. *Improvements in the manufacture of vinegar.* Dated March 10, 1862.

For the purposes of this invention weak saccharine liquors, consisting of what are known as charcoal-washings or char-washings, steamings of casks, bag filter washings, and the setel washes of sugar refiners are used. These are mixed together so as to form saccharine solutions of not higher specific gravity than about 30° Beaumé. As these solutions are almost invariably acid, they are neutralized, or even rendered slightly alkaline, by adding to them a suitable quantity of caustic lime, slaked lime, or carbonate of lime in a state of minute division; baryta, strontia, whether caustic, slacked, or in the state of carbonate, may also be used, though preference is given to the lime, its hydrate or carbonate. These neutralized or alkaline saccharine solutions are then introduced into suitable fermenting tuns, where they are mixed with a suitable quantity of ordinary yeast, and sometimes with German yeast in the state of cream. The solutions are kept at a suitable temperature till the various fermentation is completed. *Patent abandoned.*

639. C. Massi. *Improvements in means and apparatus for retarding and stopping carriages used on railways or common roads.* Dated March 10, 1862.

Here the inventor takes a carriage, to the tyres of the wheels of which the ordinary blake block is applied and fixed in the usual way. To the other end of the lever actuating the brake block, or to another lever, keyed, or otherwise fastened on to a shaft, when two or more wheels have the brake applied to them. He fixes a keeper, which is attached thereto by screws or rivets, but he prefers to arrange it so that the keeper shall be capable of adjustment when desired. Opposite to this keeper he places a horse shoe magnet of soft iron, with a copper coil outside thereof, constructed in the way now well known and practised in the manufacturing electro magnets; one end of the wire coil is attached to the galvanic battery, and whenever the apparatus requires to be used, the other end of the coil is brought into contact with the battery in like manner. The effect of this is, that as soon as the soft iron horse-shoe is magnetized, the keeper attached to the brake lever is forcibly drawn towards it, and the brake forthwith presses against the circumference of the wheel, with a degree of power proportioned to the strength of the magnet, thereby retarding or stopping the carriage. *Patent abandoned.*

640. R. A. Brooman. *Improvements in producing, by the aid of photography, copies of maps, charts, plans, and drawings.* (*A communication.*) March 10, 1862.

This invention is for the production by the aid of photography, of copies of charts, plans and drawings of the same size as, and without destroying or injuring the originals. The invention is applicable to line drawings, washed or coloured, or not, and to the reproduction of written or printed music, and this without a negative, which is required in all other methods of working photographically. The invention consists:—First: In tracing on transparent drawing cloth, the design, map, chart, plan, drawing, and other impression or device to be reproduced; the cloth preferred is "Husson cloth," but any other description of transparent cloth capable of receiving an equal tension on all sides in the frame used to pull the negative proof, may be employed. Second: In taking a sheet of paper sufficiently strong that it will not be liable to be torn during the several manipulations in albuminizing it, and preparing it with azotate of silver, in the proportion of about 1 part by weight, to 5 parts by weight of water. This paper is substituted for ordinary plates (clichés). It will be understood that plates are thus obtained much larger than glasses prepared with albumen or collodion could afford. The inventor prepares the stone in such a manner that fatty bodies do not adhere to it, that is, those fatty bodies generally used in lithography. The stone is coated, in a dark chamber, with a varnish composed of organic matters, and of chromate or bichromate of potash, or ammonia, When the stone has become dry in the dark chamber, he places the paper or positive plate upon it, with the design in contact with the stone; on this he places a sheet of glass, to keep the design in contact with the stone; he then exposes the whole to the action of light, say from 1 to 15 minutes, according to the intensity of the light. He returns the stone to a dark chamber, and washes it with white wine, or other liquid capable of attacking the soluble parts of the varnish, may be employed. All those parts of the varnish which have been preserved from the light by the lines in the design are soluble, and are removed by this first washing. He washes the stone with water, to thoroughly clean the spaces produced in the varnish by the action of the white wine. The washing with the white wine must be effected lightly, else the varnish will be removed throughout, and the impression will not be good. After this operation, the stone has the design on it, and the rest of its surface is covered with varnish. The stone being perfectly dried, he passes over it soapy water, and then dries it. He again washes with clear water and inks the stone with the ink hereafter mentioned, which only takes on that part not protected by the varnish; he then removes the whole of the varnish, and the design is in black, on the white ground of the stone, which is damped, inked with transfer ink, and acidulated. The impression is left 24 hours. Stones prepared in this manner are capable of yielding many impressions by the means employed in lithography. *Patent completed.*

641. W. Parker and G. H. Batman. *Improvements in steam engines.* Dated March 10, 1862.

This consists in providing cylinders with double pistons held firmly together by a strong connecting plate or arm, in which the crank pin is caused to take, through the intervention of a slat opening therein, so as to work and thereby communicate direct rotary motion to the driving shaft, the said cylinders being formed or furnished with suitable side openings for the reception of the cranks, shaft, and bearings, as also small friction rollers used for facilitating the movement of the slide valves. *Patent completed.*

642. W. Spence. *Improvements in projectiles.* (A communication.) Dated March 10, 1862.

This consists in forming the projectile, in two or more sections (by preference?) so put together that they will separate when fired from a gun, the front section striking directly the object at which it is aimed, and the hinder section or sections diverging a little, and striking near the point struck by the first section. *Patent completed.*

643. W. J. Bennett. *An improved solution or preparation to be used with Portland and other cements for the production of artificial stone, or for building purposes.* Dated March 10, 1862.

Here the main object is to expedite the setting of the cement, and thus to permit of the speedy removal of the casts from the moulds. This the patentee effects by introducing into the water, used to saturate the cement and bring it to a plastic state ready for moulding, a fluid compound consisting of a solution of carbonate of soda or its equivalent with sal ammoniac and alum. *Patent completed.*

644. A. C. MacLeod. *Improvements in ventilating hats and coverings for the head.* Dated March 10, 1862.

The object of this invention is effected by apertures or tubes in the body of the hat, corresponding or approximating to the top of the head of the wearer, the said apertures or tubes being protected by a projecting band or fillet also provided with apertures; or, instead of any apertures in the fillet, there may be apertures in the brim, or in both fillet and brim, the apertures in the body being always necessary. *Patent completed.*

645. W. S. Nosworthy. *Improvements in upright and horizontal pianofortes.* Dated March 10, 1862.

The objects of the improvements are to bring the pianist, whilst sitting at the instrument, to the height or thereabouts of the vocalist or other artist, while such vocalist or other artist is standing on the ordinary level of the room, and to enable the vocalist to read from the copy of music used by the pianist without stooping and compressing the chest. A vocalist may also accompany himself on the instrument in a standing position without bending the body. For these purposes, in the case of upright pianofortes, the patentee fixes the pedals in the bottom door, or panel below the keys, at the required distances above the bottom of the instrument, with a raised seat and a step or footboard attached thereto. Otherwise he fixes a footboard to the instrument, which will not extend beyond the key-board, into which he fixes the pedals, so that the vocalist shall stand on the ordinary level of the room. The seat may be attached to the footboard, to fold or shift beneath the keyboard. *Patent completed.*

646. A. Barclay. *Improvements in traction engines, and in apparatus for indicating the pressure of steam.* Dated March 10, 1862.

Under one modification of this invention an ordinary tubular locomotive boiler is arranged within a rectangular framing. The engine runs upon two driving wheels of large diameter, arranged towards the front end of the engine, the backward end being supported by a single trailing wheel fitted in the centre of the framing beneath the foot plate. The pair of driving wheels run loosely on the main axle, and each wheel is driven by a distinct pair of engines, arranged on the opposite sides of the framing. The main axle extends sufficiently beyond the framing to admit of the cylinders of each pair of engines, and their connected parts being arranged between the framing and the inner faces of the driving wheels. The two cylinders on each side are bolted to brackets projecting laterally from the framing, and they are placed in a diagonal position, with their upper ends converging and directed towards the driving shafts above. The upper ends of the piston rod of each cylinder traverses in a guide cast on the cylinder cover. The piston rods of each pair of engines are connected to one of two crank shafts arranged above, each shaft giving motion to one of the driving wheels, and being quite distinct from its fellow wheel. Extending upwards from the side pieces of

the framing are two standards, in the upper parts of which, are fitted the bearings of the duplex crank shafts. One pair of engines is coupled to one of the crank shafts on one side of the framing, and the other on the opposite side, each having the usual eccentrics for reversing the motion of the engines. On the opposite, or free extremity of each crank shaft, is a pinion, which gears into the teeth of an annular wheel, formed on the inside of the rim of each driving wheel. The rotatory movement imparted to each crank shaft, causes the pinion to actuate the driving wheels, and so propel the machine in either direction, as desired. The eccentrics of each pair of engines are actuated by a pair of hand levers arranged one on each side of the fire box, similar to the ordinary locomotive engines, and connected to the eccentrics above by a suitable arrangement of a central lever and connecting links. The guiding of the machine is preferred to be effected solely by the steam being caused to check the speed of one wheel whilst that of the other is increased. The second part of the invention relates to the arrangement and construction of a pressure gauge to be used with this and other engines. *Patent completed.*

647. J. B. G. M. F. PIRET. *Improvements in lubricating apparatus.* Dated March 10, 1862.

This invention is not described apart from the drawings. *Patent completed.*

648. J. T. CALOW. *A safety apparatus applicable to cages or hoists used in mining or lifting machines.* Dated March 10, 1862.

This consists essentially of a spring or springs, and a weight or weights connected to and acting upon mechanism for gripping the slides, guides, or conductors, in case of accident, the said spring or springs having a bearing or foundation on the cage or hoist, while the weight or weights hangs or hang from or rest upon the spring or springs, so as to neutralize or counteract the tendency of such spring or springs to bring the grips into action while the cage or hoist remains suspended or supported. *Patent completed.*

649. M. HENRY. *An improvement in preparing hooks and eyes for sale or consumption.* (A communication). Dated March 10, 1862.

According to this invention, boxes, cases, or envelopes are used for holding the hooks and eyes as before, but a sample or pattern hook or hook and eye is attached to such box, case, &c., so as not to be separated therefrom by the opening thereof. For this purpose the pattern is fastened upon cardboard or other material, on the back of which paper or other substance is stuck so as to conceal the attaching thread or agent, and this is caused to adhere or is attached to the box, case, &c., which can be opened without separating the sample, and the attaching thread is connected at the back. *Patent abandoned.*

650. H. H. KROMSCHROEDER. *Improvements in gas meters.* Dated March 10, 1862.

This invention relates to that class of meters in which the measuring drum consists of a series of eccentric measuring chambers, and in which a hollow floating cylinder is within the measuring drum, and comprises a great amount of detail which we cannot devote space to here. *Patent completed.*

651. R. PEACOCK. *Improvements in the manufacture of window blinds.* Dated March 11, 1862.

Here the inventor makes use of paper made from the ordinary materials, of suitable thickness and demensions, according to the size of the blinds to be produced, and this paper is either dyed, stained, printed, painted, photographed or otherwise ornamented of the desired colour and pattern. *Patent abandoned.*

652. J. NADAL. *A Portable Fountain for water and other liquids.* Dated March 11, 1862.

Here the object is for the construction of a portable fountain, in which a constant maintaining puts in motion a number of pumps, and these cause the liquid with which the fountain is supplied to circulate through and through the jets. The motive power of the fountain is a spring capable of being wound up, as is the spring of a clock; it gives motion to a toothed wheel, which gears with and drives three, or, it may be, other number of pinions, and on the axes of these are cranks (or eccentrics; and these by connecting rods work pumps, which force the liquid through the jet or jets, which may be of any form. The liquid so formed through the jet or jets afterwards returns to the pumps, and so the action continues as long as the motive power continues, so that a very small quantity of liquid is required. *Patent completed.*

653. E. PARFITT. *A Watch Protector.* Dated March 11, 1862.

This is arranged as follows :—To the inside of the pocket in which the watch is usually carried, is fixed permanently, or connected at pleasure, a loop or ring, through which the end of the albert chain is passed, and then attached to the watch. When it is required to look at the watch, the hand must be put into the pocket and the watch lifted out. Any attempt to draw out the watch by the chain will be prevented by the loop or ring. *Patent abandoned.*

654. W. BARTER. *Improvements in apparatus for propelling vessels, and for enabling them to work off lee shores during storms.* Dated March 11, 1862.

This consists in an arrangement of apparatus, by means of which the rising and falling motion given to the vessel by the waves is made available to give the vessel a forward impulse. *Patent abandoned.*

655. E. HUMPHRYS. *Improvements in steam-engines.* Dated March 11, 1862.

This relates to that description of steam-engines in which two cylinders—a small one, into which the steam first enters, and a larger one, into which it is subsequently allowed to expand—are employed, and in which the pistons of the cylinders are connected together by a piston-rod passing through the cover or partition which separates the small from the large cylinder. The improvements consist in applying a trunk to the large piston, and a suitable connecting rod, as in ordinary trunk engines, to transmit the power from the two pistons to a crank on a shaft or axis. *Patent abandoned.*

656. O. KERAUTRET and I. KERAUTRET. *Improvements in the construction of buildings, by the use of which hewn stone and faced bricks are dispensed with in some parts thereof.* Dated March 11, 1862.

This consists in moulding in the position they are to occupy all the architectural forms to be given to the building. The patentees use ordinary rough unhewn stone, which they bind together with good cement mixed with sand. *Patent completed.*

657. E. G. CAMP. *Improvements in brushes or apparatus for brushing.* Dated March 11, 1862.

This apparatus for brushing is specially designed for brushing the human hair in a new and improved manner, and is intended especially for the use of hair-dressers, but is also applicable for use in baths as a skin brush. The apparatus consists of a shaft, with a loose handle at each end, a fixed pulley for receiving motion, and a drum on which the brushes are mounted. In the manufacture of these brushes the patentee takes the materials now usually employed for that purpose, viz., bristles, split whalebone, and metal wires. When metal wires he magnetizes them or not while in use. For the purpose of causing these brushes to rotate, he drives them by a belt passed round the pulley on the brushing apparatus, and round fast and loose pulleys driven by hand or by steam or other power. To use the brush he holds the apparatus steadily with both hands, and directs it to any and all parts of the hair, in whatever position the head may be held, the brush being made to rotate all the time. For the convenience of washing he fastens the brushes to the drum by springs which admit of their being removed. The drum itself is not fixed to the shaft, but slides off and on, and is carried round by a lock and key adjustment. *Patent completed.*

658. C. HALL. *Improvements in implements for breaking up the soil, and in ropes and drums to be employed in the cultivation of the soil by steam.* Dated March 11th, 1862.

This invention consists, first, in constructing implements for breaking up the soil, as follows:—The patentee takes a sharp-cutting steel bar, of any convenient width, set at an angle to the line of draught, whereby the depth this cutting-bar travels under the surface is regulated. He screws into this bar, at intervals, sharp cutters, which direct the soil, and at the same time raise the weeds and roots to the surface. According to the shape of the cutters so will the soil be turned. Hitherto wire ropes have been used for drawing implements in steam agriculture, and they become soon worn, and possess other defects. Now, the second part of this invention consists in constructing ropes, as hereafter described, which he substitutes for wire ropes, and he uses with these ropes, drums, which he constructs as also hereafter described. He takes bars or rods of steel, or iron, though he prefers steel, and of a length determined by the length of the divisions of or on the drum, and he unites the bars or rods by means of short links, or by means of eyes, through which a pin is inserted; or he employs any other suitable means of junction. He forms the drums with the periphery divided into parts; the length of each separate part corresponds with the length of the bars or rods in the chain to be used with it, with a space or provision for the reception of the link or joint between every two bars or rods. For instance, the drum may be composed of three sides or divisions, the surfaces of which may be flat or curved for the bars or rods in the rope to bear against, or be received upon, while the links or joints would be received upon or in the parts forming the ends of the divisions. Again, the drum may be circular, with sunk recesses for the reception of the connections between the ropes. Drums made according to this invention will, in every case, have a direct grip upon the ropes constructed according to this invention, the drums and ropes being calculated to be used together. *Patent completed.*

659. T. B. WILSON. *Improvements in means or apparatus for the splitting of cane and other fibrous substance.* Dated March 11th, 1862.

For splitting cane in the direction of its length the patentees employ rollers in pairs, with grooves around them; and in front of these rollers, opposite such grooves thereof, they place knives or cutters in positions and of forms adapted to the number and form of the divisions desired to be produced. By causing the rollers to revolve, and passing the cane or other fibrous matters to be cut in the ground channels in them, the rollers will conduct the cane or other matter to the cutters, and the desired separation will be effected. *Patent completed.*

660. H. BAYNES. *An improvement in bankers' cheque-books.* Dated March 11th, 1862.

This consists essentially in inserting in the ordinary cheque-book a leaf containing a suitable form of order or request to the banker for a new cheque-book, which order or request must be signed by the same party, and in the same manner as a cheque would be signed. *Patent abandoned.*

661. R. SMITH. *Improvements in telegraph posts.* Dated March 11th, 1862.

This relates to improved modes of forming and combining a number of short lengths to form each telegraph post. The top length is of wood, and the bottom length entered into the ground is tubular, and usually of cast-iron, whilst the intermediate lengths are tubular, and usually of thin malleable iron. The separate lengths are made slightly tapering, and so that the top of one may fit inside of the next above it, like a spigot and faucet. The lowest malleable-iron length is fixed upon the cast-iron bottom length by means of pinching-screws, which are entered through an external ring. The spigot, or small end of each malleable-iron length, is by this invention formed with an indentation or corrugation running round it, to give it sufficient strength to sustain the portion of the post above it. *Patent abandoned.*

PROVISIONAL PROTECTIONS.

Dated May 12, 1862.

1426. C. J. Neale, High Oakham, Nottingham, gentleman. Improvements in apparatus for measuring and registering corn and other grain.

Dated June 20, 1862.

1816. J. B. T. Detuncq, Quesnoy le Montant, France, farmer. Improved apparatus or machinery for treating flax or hemp.

Dated June 21, 1862.

1835. H. Gonnon, Saint Nazaire, Loire Inférieure. Improved machinery for making bricks.

Dated June 26, 1862.

1878. J. Martin, Rue de Bordeaux, Perigueux, France, engineer. Improvements in reaping and mowing machines.

Dated July 21, 1862.

2071. W. E. Gedge, 11, Wellington-street, Strand. Improved excavating or boring apparatus. (A communication.)

Dated July 28, 1862.

2129. C. W. Eddy, 8, Warwick-terrace, Belgrave-road, Hanover-square. Improvements in the means of impeding the entrance of ships and vessels, and in particular of screw ships into channels.

Dated July 29, 1862.

2146. J. Mackenzie, of Arundel-square, Islington, engineer. Improvements in shaping machines for curvilinear surfaces.

Dated August 1, 1862.

2183. R. Nurse, Machen, near Newport, and D. Nurse, Pontymister, Monmouth. An improved annealing pot.

2185. C. H. Plevens, Dunstan-hall, Derby, colliery owner, and H. Rider, Rotherham, York, colliery engineer. Improvements in the construction of colliery waggons, tubs, or corves, and in apparatus for tipping or discharging the same.

Dated August 5, 1862.

2197. J. Higgin, Manchester, manufacturing chemist. An improved substitute for cow dung used in printing and dyeing texile fabrics or yarns.

Dated August 7, 1862.

2212. F. H. M. C. D. C. De F. de Lacombe, Paris, gentleman. Improvements in the means of lighting towns or other localities, and of ventilating, warming, and providing the same with water.

Dated August 9, 1862.

2232. J. J. H. Gebhardt, Lawrence-lane, City, merchant. An improved fastening for purses, pocket-books, needle-books, ladies' companions, instrument cases, and other similar articles. (A communication.)

Dated August 18, 1862.

2317. J. Brière, Brussels, Belgium, mechanician. A continuous self-acting condenser, being a new boiler-feeding apparatus.

2327. W. Whittle, Smethwick, mechanical engineer. Improved machinery for the manufacture of nails and spikes.

Dated August 20, 1862.

2329. H. Whittaker, Church, near Accrington, Lancaster. Improvements in healds or heddles, and in the manufacture of the same.

Dated August 23, 1862.

2354. J. Edwards, 77, Aldermanbury. Improvements in the permanent way of railways.

Dated August 26, 1862.

2362. H. R. Hughes, 31, Mottram-street, Stephen-street, Salford. Improvements in the construction of sawing machines.

2363. W. E. Gedge, 11, Wellington-street, Strand. Improvements in stays or corsets. (A communication.)

2364. J. and B. Harrison, Otley, York, farmers. Improvements in clod crushers.

2367. L. Jarosson, La Madelaine, near Lille, France, chemist. An improved process and machinery for bleaching or washing texile fabrics and materials.

Dated August 7, 1862.

2375. W. H. Turner, Blackburn, cotton spinner. Improvements in machinery or apparatus for carding cotton and other fibrous materials.

2376. C. Clark, 361, City-road. Improvements in tea and other trays for the table, and in urns and apparatus intended to be used therewith.

2377. G. Lindsay, Belfast, engineer and machinist. An improved mode of arranging and disposing guns in ships employed in naval warfare and otherwise.

2379. R. A. Brooman, 166, Fleet-street, patent agent. Improvements in machinery for separating or sorting and washing coal and other minerals, (A communication.)

2381. J. G. Nutting, Regent-street, button manufacturer. An improvement in the manufacture of buttons.

2383. A. H. W. Cook, Norwood. Improved apparatus for obtaining motive power, applicable for driving machinery or for other purposes where a motive power is required.

Dated August 28, 1862.

2385. J. Kitchin, Liverpool, ventilating engineer. Improvements in ventilators.

2389. J. J. Moeckel, Rouen, engineer. Improvements in machinery or apparatus for spinning cotton, wool, or other fibrous materials.

2391. W. Husband, Hayle, Cornwall. Improvements in water valves.

2393. C. Humfrey, Suffolk-grove, Southwark, oil merchant. Improvements in the treatment of petroleum to render it non-inflammable.

Dated August 29, 1862.

2395. H. Jones, Birmingham, gun manufacturer. Improvements in breech-loading fire-arms.

2397. W. Smith, 19, Salisbury-street, Adelphi, civil engineer. Improvements in the construction of furnaces. (A communication.)

2399. H. Harben, Oxford-villa, Haverstock-hill, gentleman. Improvements in the manufacture of cotton, cotton fibre, and other similar fibrous productions.

2403. R. Courtenay, Craigton, Kingston, Jamaica. Improvements in obtaining motive power.

2405. E. A. Pontifex, Shoe-lane, City, engineer. Improvements in steam traps or apparatus for facilitating the escape of condensed steam.

Dated August 30, 1862.

2407. E. C. Harding and C. Doody, Manchester. Improvements in braces.

2411. J. Meyer, Kennington, mechanician. Improvements in mechanism for the production of Jacquard cards, and in the said cards or card bands.

Dated September 1, 1862.

2413. J. Nickson, Manchester, plasterer, and T. Waddingham, jun., architect. An improved foundation or groundwork for plaster for ceilings, walls, partitions, and other purposes.

2415. W. E. Gedge, 11, Wellington-street, Strand. Improvements in apparatus for washing the felts of papermaking machines. (A communication.)

2417. J. W. Newton Moor, Chester. Improvements in machinery or apparatus for preparing, spinning, and doubling cotton, wool, and other fibrous metals.

2421. W. Clark, 53, Chancery-lane, engineer. Improvements in the means of obtaining light and heat, and in apparatus for the same. (A communication.)

2423. J. H. Johnson, 47, Lincoln's-inn-fields, gentleman. Improvements in apparatus for regulating or controlling the working of motive-power engines, applicable also to the regulation of the flow of liquid, air, or gas through pipes or conduits. (A communication.)

Dated September 2, 1862.

2429. R. Waygood, Newington, engineer. Improvements in steam boilers.

2431. J. B. Thompson, Moreton-place, St. George's-square. Improvements in electro-magnetic machines.

2432. Sir W. O'S. Brooke, Euston-place. Improvements in the construction of submarine telegraphic cables.

2433. A. Johnston, 49, Arlington-street, Woodland-road, Glasgow. Improvements in machinery for pressing cotton and other materials, and in bands for retaining the same in bales.

Dated September 3, 1862.

2435. H. Elliott, Birmingham, gun maker. A new or improved apparatus for extracting the cases of pin cartridges from breech-loading fire-arms, and for re-capping, re-charging, and closing or turning in the said cartridge cases.

2437. G. Walton, Bradford, York, manufacturer. Improvements in circular box looms.

2439. W. Clark, 53, Chancery-lane, Engineer. Improvements in musical instruments. (A communication.)

2441. R. A. Brooman, 166, Fleet-street, patent agent. Improvements in tools for boring, and in apparatus for working the same. (A communication.)

2442. R. A. Brooman, 166, Fleet-street, patent agent. Improvements in apparatus for transmitting electric telegraph messages and signals. (A communication.)

2443. P. J. Bossard, Kennington-road, merchant. Improvements in stoppers for bottles, jars, guns, tubes, and other open-mouthed articles, in taps, and in fixing them in casks and other vessels. (A communication.)

Dated September 4, 1862.

2445. B. F. Cowan, Victoria Hotel, Euston-square, gentleman. Improvements in cannon and other fire-arms.

2449. R. P. Coles, Englefield-road, Islington, surveyor. Improvements in the construction of the permanent way of railways.

Dated September 5, 1862.

2451. W. Slater, Little Bolton, Lancaster, manager, and W. R. Harris, engineer, Salford. Improvements in self-stripping carding engines for preparing cotton and other fibrous substances or materials.

2453. H. W. Hart, Fleet-street, engineer. Improvements in argand and other burners.

2454. D. A. Samuel, Belvedere, Kent. Improvements in apparatus for steering vessels.

2455. J. S. Margetson, Cheapside. Improvements in the manufacture of the material intended for scarfs or cravats, and in the machinery employed therein.

2456. W. Wells, Ryder's-court, Leicester-square. Improvements in horse shoes, and in the method of fastening the same.

2457. W. E. Newton, 66, Chancery-lane, civil engineer. Improvements in lamps. (A communication.)

2458. S. H. Hadley, City Mills, Upper Thames-street. An improved process for manufacturing gas for illumination.

2459. J. R. Johnson, Stanbrook-cottage, Hammersmith, and J. A. Harrison, 25, St. Andrew's-road, Southwark. Improvements in apparatus for taking photographic panoramic pictures.

Dated September 6, 1862.

2460. S. H. Huntly, 50, Upper Baker-street, Regent's-park. Improvements in cooking apparatus, more particularly applicable to the requirements of the army and navy.

2461. J. Snider, jun., 51, Dorset-street. A new and useful method of increasing the durability of, and for preserving cloths and other like fabrics used for sails, tarpaulings, tents, and other coverings; also all kinds of ropes and cables and telegraph wires; also all woods, metals, and other materials used in buildings or constructions on land or on water; and all objects exposed to the action of acids, alkalis, gases, fire, fresh or salt water, atmospheric or other like destructive influences, by the application of graphite.

2462. S. Pudney, 37, Manor-street, Clapham. Improvements in apparatus to be used in the manufacture of sulphuric acid.

2463. H. Hughes, Homerton, engineer. An improved frilled and fluted fabric or material, and improvements in fluting or goffering machines.

2464. E. L. Duncan, Inverness-road, Bayswater. Improvements in the manufacture of splints.

2465. J. H. Johnson, 47, Lincoln's-inn-fields, gentleman. Improvements in fire-arms and projectiles. (A communication.)

2466. W. J. Curtis, Tufnell-park-road, Holloway, civil engineer. An improved construction of breech-loading cannon.

Dated September 8, 1862.

2468. C. W. Williams, Liverpool, gentleman. Improvements in steam boilers.

2469. F. D. Artingstall, Manchester, balance-maker. Improvements in balances.

2470. J. S. Crosland, Ashton-under-Lyne, engineer. Improvements in the manufacture of tubes made of copper, and of copper combined with other metals.

2475. G. Davies, 1, Serle-street, Lincoln's-inn, civil engineer. Improvements in railway signals. (A communication.)

2476. A. J. Alderman, 59, Guildford-street, Bloomsbury, gentleman. Improvements in ships' windlasses, capstans, and cable stoppers, applicable generally to hauling and working with chains.

Dated September 9, 1862.

2477. J. Webster, 142, Woodbridge-road, Ipswich. Improvements in preventing the incrustation of steam boilers.

2478. P. Rainier, The Cedars, Shirley, near Southampton, lieutenant in the Royal Navy. Improvements in watches, chronometers, and other time-keepers.

2479. J. Maurice, 3, Langham-place, Regent-street, dentist. Improvements in the construction and preservation of ships and vessels.

2480. F. Selby, Surbiton, engineer. Improvements in traction engines, and in valves for traction engines where compound engines are used, which latter improvements are applicable to compound engines generally.

2481. W. Hirst, Halifax, bookkeeper. Improvements in machinery to be employed in the manufacture of paper or linen spool tubes, which machinery is also applicable for the manufacture of cartridge cases.

2482. J. Walker, Norwich, millwright. Improvements in the manufacture of oil presses.

2483. T. Fleitmann, Iserlohn, Prussia, Doctor of Philosophy. Improvements in the manufacture of copper from copper ores.

Dated September 10, 1862.

2485. J. Saunders, 7, Mordin-place, Lewisham-road, engineer. A new or improved railway break.

2487. W. Rothera, Hollingwood, near Manchester, bolt maker and machinist. Improvements in machinery or apparatus for riveting boiler plates, tanks, and similar articles.

2489. J. Vigouroux, Nimes, France, metal founder. An inoxydable white metal suitable for making taps or cocks and other useful articles.

2491. G. Ritchie, Edinburgh, brewer. Improvements in extracting the liquid portion of yeast, spent hops, or other similar matters, and in the apparatus employed therein.

2493. A. Rigg, jun., Chester. Improvements in apparatus for carrying and tipping coal and other minerals, and in steam breaks used therewith, and with other machinery.

Dated September 16, 1862.

2536. E. Astel, Paris, France, draughtsman. Improvements in urinary utensils, also applicable to fixed and portable commodes.

LIST OF SEALED PATENTS.

Sealed September 19, 1862.

767. R. A. Brooman.

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

1405. R. Moore. Improvements in the structure and appliances of ships and other vessels.

1407. R. Willoughby. Exhibiting and giving rotatory and traversing motion to placards, advertisements, scenes, and other objects.

1421. H. S. Firman. Washing and cleansing textile fabrics. (A communication.)

1426. C. J. Neale. Measuring and registering grain.

1438. A. Wormull. Trepanning instruments.

1440. J. H. Johnson. Purification of oils. (A communication.)

1444. W. Hartican. Fire-escape apparatus.

1445. R. A. Brooman. Shunting trains. (A communication.)

1447. W. Southwood. Machinery for manufacturing nails.

1448. R. M. Latham. Steering apparatus. (A communication.)

1456. A. Smith. Balances.

1457. E. Whittaker and J. Claro. Machinery for preparing fibrous materials.

1459. J. Smith. Thrashing machines.

1460. J. C. Brant. Construction of armour-plated ships.

1462. J. Fletcher and J. W. Fuller. Machinery for rolling, bending, and planing metals.

1468. W. Sissons. Machinery for driving piles by means of steam hammers.

1469. G. H. Birkbeck. Consuming smoke. (A communication.)

1470. J. Stone. Pumps and fire-engines.

1474. C. Tress. Manufacture of hats, helmets, bonnets, or caps.

1475. I. Baggs, and W. Simpson. Treating straw, Spanish grass, and other vegetable fibres.

1477. A. Watney. Constructing ships.

1484. A. A. Lamiable. Cementing cast and wrought iron.

1485. A. L. Thirion. Carriages.

1487. D. C. Le Souëf. Embossing metal plates. (A communication.)

1499. E. Talbouis. Knitting frames.

1501. J. Broadley. Weaving.

1524. W. Clark. Hydraulic wheels. (A communication.)

1526. M. Vogl. Protecting buildings from burglars.

1527. J. Kennedy. Propellers.

1531. J. Kennedy. Plates for plating and forming the outside skin of ships and vessels, and in protecting the same from fouling and oxidation.

1533. M. A. le B. Virloy. Drying and carbonizing wood, peat, and other fuel.

1534. W. Bush. Armour for ships and batteries.

1545. S. T. and F. Turnbull. Manufacture of floorcloths.

1556. C. de Bergue. Manufacture of metal reeds for weaving.

1558. J. Webster. Coating and indurating metals.

1567. C. de Bergue. Supporting coverings or surfaces.

1588. F. Tolhausen. Method of applying various mineral and organic substances to wire-gauze. (A communication.)

1598. J. Simpson. Cutting or producing "mouldings."

1607. J. H. Johnson. Manufacture of tinned lead pipes. (A communication.)

1645. H. Watson and J. Millbourn. Pulp strainers.

1721. F. Giachosa. Ventilating mines.

2172. J. R. and E. Ranson. Mounting mill-stones.

2176. W. E. Newton. Lubricating compounds. (A communication.)

2197. J. Higgin. A substitute for cow-dung.

2214. R. A. Brooman. Ships and vessels. (A communication.)

2287. D. P. Marques. Cleaning the bottoms of ships. (A communication.)

2328. C. Callebaut. Sewing machines.

2374. R. Sims. Machinery or apparatus for pulping, stripping, or slicing vegetable substances.

2380. W. E. Newton. Artificial illumination. (A communication.)

2413. J. Nickson, and T. Waddingham, jun. Foundation or groundwork for plaster for ceilings, walls, and partitions.

2432. Sir W. O'S. Brooke. Telegraphic cables.

The full titles of the patents in the above list can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list who have given notice of their intention to proceed, within twenty-one days from the date of the *Gazette* in which the notice appears, by leaving at the Commissioners' office particulars in writing of the objection to the application.

PATENTS ON WHICH THE STAMP DUTY OF £50 HAS BEEN PAID.

2110. T. Richardson.
2113. J. Luis.
2142. A. Lamb.
2152. R. Davison.
2138. A. Manbré.
2139. W. Weild.
2193. T. Sutton.
2213. W. Hartley.
2291. W. Irlam.

PATENTS ON WHICH THE STAMP DUTY OF £100 HAS BEEN PAID.

2092. J. Lewtas.
2113. G. A. Biddell.
2125. W. Pollitt, and J. Eastwood.

THE
MECHANICS' MAGAZINE.

LONDON, FRIDAY, OCTOBER 3, 1862.

GUNS AND ARMOUR PLATES.

WHEN the mimic naval warfare at Shoeburyness is replaced by the actual conflict of iron-cased fleets, there will be a crisis in England's maritime supremacy. The best naval gun and the best naval armour will carry the day. It behoves us, then, to watch with jealous scrutiny the target experiments for testing guns and plates, which deservedly engross public attention, and make it the duty of the journalist to chronicle the results truthfully, without official or personal bias. In this spirit we propose to comment upon the trials at Shoeburyness with the Whitworth and Horsfall guns, and beg to refer to a summary of the experiments of last week from our own reporter in another column.

The reports in *The Times* of ordnance experiments are usually received by the public as authentic, and are not unfrequently referred to in Parliament as graphic and correct, so that they assume a semi-official character. We have frequently had occasion to warn our readers against placing implicit reliance on those reports, because they are usually one-sided, giving results and conclusions in an official point of view in support of the Admiralty or Ordnance departments. Of the caution with which it is necessary to receive the impressions conveyed in the columns of the leading journal, the report of the Whitworth and Horsfall experiments afford a striking example. In defiance of truth, in opposition to facts well known to the reporter, or those persons in office who furnished the data, with reference to the construction of the Whitworth 120-pounder naval gun, it is asserted in *The Times* that this most formidable and successful assailant of armour plates is "manufactured "on Sir W. Armstrong's wrought iron coil "principle, *but* with the beautiful hexagonal "bore of Mr. Whitworth's mode of rifling." This "but" is astutely meant to convey the idea that the Armstrong and Whitworth guns differ in no respect but in the rifling. This is simply untrue. The mode of construction, as described by our reporter, differs essentially in principle and in details, the results being greater initial velocity, greater power, and greater strength and security, with greater facility in loading, all in favour of the Whitworth. In the comparison of the projectiles, the Armstrong is completely outdone. Whilst the conical shot and shell of the latter, at 200 yards' range, have no penetrating force, and are shattered into atoms by impact against a $4\frac{1}{2}$-in. plate, the Whitworth projectiles of both kinds pierce the same thickness of iron through and through at 600 yards. It is true that *The Times* afterwards admits that to pierce "any iron ship the Armstrong is out of the "question;" but, without the explanation we have given, the reader of the report would suppose there is no difference between the guns but in the rifling.

The same authority then, again untruthfully, thus describes the trial of the Horsfall gun,—"this huge and most unwieldly piece "of ordnance (its weight is not less than 24 "tons) was tried at the same mark, and, as "will be seen, with very different and most "unsatisfactory results." This description we must designate as spiteful. So far from being borne out by the facts, it is a disingenuous misrepresentation. We are assured by our reporter that on the ground the performance of the Mersey gun was regarded as a great success. The effects of the one effective shot, at 800 yards, are unparalleled, and we may say unapproachable by any other piece of ordnance of any country; and when we consider its terrific destructive effects at 200 yards, at the first trial, and add the fact, that it has been fired about one hundred times, and remains as sound and strong as the day it was finished, the principle of its construction, by the test of actual practice—the best of all evidence—is proved to be good. Under this test the 150-pounder Armstrong broke down; and whatever may be said of the 110-pounder Armstrongs, it is notorious that many of them came to grief.

The inaccuracy of aim of the Mersey gun is greatly exaggerated by the *Times*. Including the pioneer, which, as with the Whitworth, was only fired to test the range, and was not intended to hit the target, four shots were fired—the first does not count. Of the other three two struck the target, so that, considering the long range (800 yards), the hazy state of the atmosphere, and the "miserable sighting," as described in our report, the practice was excellent. At the trials of the 150-pounder Armstrong, at much shorter range, it is notorious that many shots went wide of the mark, and there were as many misses, proportionally, as with the Horsfall last week. This gun being provided with proper sighting apparatus will be as accurate in aim as any other gun of the same calibre. The parenthetic note, "its weight is *no less than* 24 tons," is childish. It is an inevitable condition of a gun of this calibre to be of great weight, and it is Sir W. Armstrong's futile attempts to build up great guns of lighter weight, in contravention of this law, which is one cause of his failure. In the numerical nomenclature of guns, a fallacy is introduced by the titled Director of Artillery, which is constantly misleading the public as to the real force of guns. The proper, indeed the only true test of the power of a gun, is its bore, or, in other words, the sectional area of its powder chamber; that power, therefore, is correctly measured by the diameter, and consequently by the weight, of a spherical shot fitting the bore. That is the old and the correct method. Sir W. Armstrong has introduced the manœuvre of measuring the force by the weight of an elongated bolt. Thus he and his partizans, as an artifice to mislead the uninitiated, invariably called his 150-pounder, which burst after a few trials at Shoeburyness, a 300-pounder. By the same rule the Mersey, which is a veritable 280-pounder, that being the weight of its spherical shot, might, if fired with an elongated bolt, be called a 600-pounder. Having settled this point, we assert that no large gun of the same power as the now famous Horsfall can be constructed of less weight than about 24 tons, if it is to be a really serviceable gun, constructed, not to kill the gunners who fire it, but to produce the same destructive effects on an enemy's ships as those exhibited by the single shot which, at 800 yards, smashed a great aperture through the section which represents the side of the "Warrior." Guns to bear the explosion of 75 lbs. of powder must be of enormous weight. We think it is fairly proved that the Horsfall is the largest and best monster gun which has yet been produced, and that guns of equal power cannot be made of less weight.

Having exposed the mis-statements and erroneous assumptions of the official reports, we come to the conclusions which, for the national interest, are to be drawn from the experiments under notice. We will not now go into the question of monster guns. The uses to which they are to be applied is a matter of grave consideration. The Mersey Company have triumphantly proved the possibility of their construction and their tremendous power of destruction. We have to deal with two most important and urgent questions, namely, an improved naval gun and a shell capable of penetrating thick iron plates, which the performances of the Whitworth gun and projectiles have suddenly forced upon us, and caused no little dismay in Admiralty and Ordnance circles.

As a naval gun the Armstrong is dethroned, and the Whitworth takes its place. The millions spent at Elswick and Woolwich are wasted. A weapon far superior in every respect to the 110-pounder Armstrong is produced, and its success undoubted. The exigencies of national defence imperatively demand that the latter be as speedily as possible swept away and replaced by the former; for if this be not done, it is evident that in the event of war the "La Gloire" of our enemy, armed with 120-pounder Whitworths, would, after a short contest capture or destroy the "Warrior." Those guns penetrate the sides of the "Warrior," throw explosive shells through her iron plates on to her decks, and drive the crew from their guns as if she were a timber built ship. On the other hand, the guns of the "Warrior" would produce no effect whatever on the "La Gloire," as the conical Armstrong missiles would not penetrate her plates, or in the slightest way injure or endanger her crew. There is no denying the conclusion that plates of iron, $4\frac{1}{2}$ inches thick, with wood backing, can be penetrated by explosive missiles. The theory of the impregnability of plates to shell is demolished, and thus all the converted wooden ships are as inefficient for war purposes, as the timber-built screw steamers they are intended to replace. The "Royal Sovereigns," "Royal Oaks," and "Caledonians," are, before they are brought into life, condemned as fighting ships; and the numerous fleet of partially-protected vessels, with wooden bottoms and iron-top sides, on the Reed principle, are doomed to perish still-born. This comes of precipitancy in applying methods of armour-plating without previous experiments. This comes of adopting wood as a backing, when it ought to be known to engineers that wood offers no resistance whatever to the penetrating effect of projectiles. The Whitworth system of flat-headed shot has proved that the penetration of iron plates with cannon shot is only a punching process, familiar to every riveter and boiler-maker in an iron ship yard. Given, a thickness of plate and a punch of greater diameter than that thickness, the required amount of power must drive the punch through the plate, if it meet with no resistance at the back. Here we have the true theory of the penetration of plates by projectiles; and until wood backing is dispensed with, and replaced by a rigid backing, which shall obstruct the passage of the projectile, no thickness of plate a ship can carry will keep out explosive shells, which are the "bête noire" of naval officers and sailors. We trust the engineering world will carefully consider this subject, and aid us in opening the eyes of the authorities to the danger which menaces our maritime supremacy from the favouritism bestowed on a plausible artillerist, and the dogged persistence of the men of wood, in adhering to a bad system of armour-plating.

We warn the public that the millions which are being expended on Armstrong guns and armour-plating wooden ships are a wanton and wicked waste of the national treasure.

HOROLOGY IN ENGLAND, AND AS SEEN AT THE EXHIBITION.

It has been our task on several occasions to direct the attention of our readers, and that of the public generally, to the very important branch of mechanical science known as Horology. We have felt, and very strongly felt that although the Horologists of this country have achieved for themselves a position of eminence as regards excellency of workmanship, they have not succeeded in defending themselves from the effects of the energetic efforts made by foreign clock and watchmakers to supplant them in the markets of the world. This is a fact in every way to be regretted, and somewhat difficult to be accounted for. No doubt labour is to be had at a much cheaper rate in most of the great seats of Horological industry abroad, than in those of the United Kingdom. But, as a compensation for this disadvantage, English Horologists have at hand labour-saving machinery, and abundance of mechanical skill wherewith to direct that machinery to effective purpose, and this should place them on an even footing with their opponents, if not on much higher and more commanding ground. It does not appear however, that this consideration has as yet had its due weight with those whom it most directly concerns, and the consequence is, that in the great competition which is the result of free trade, they are out-distanced by their nimble-fingered foreign rivals.

For ourselves we shall not cease to impress upon British clock and watchmakers the absolute necessity of their availing themselves of the assistance of members of those other branches of mechanical art which are nearly allied to their own, and who have maintained their superiority over all comers. They *must*, if the declension in their trade is not to lead to its final extinction, take council of engineers and general mechanics, and employ the means, which those skilful and intelligent men would readily suggest, for enabling them to produce better timekeepers at a cheaper rate than the meretricious, and superficial importations from France, Switzerland, and America. One horologist, whose persevering employment of the printing press for the purpose of disseminating a knowledge of the asserted excellence of his wares is remarkable, and probably of much advantage to himself, has suggested the enlistment of battalions of women into the ranks of clock and watchmakers. Against this proposition we have little to urge, but we should be glad to learn whether the gentleman in question has tried the experiment himself on anything like a large scale, or on any scale at all, and whether he finds it as admirable in practice, as in theory he makes it appear. We contend for improved and multiplied mechanical appliances as the best adjuncts to horology in England, and we believe that they alone can save it, and its professors, from that oblivion towards which they are apparently drifting. It is, we need hardly assure the class of mechanists to whom these remarks are particularly addressed, with an honest and conscientious wish to serve them, and at the same time to place their useful and beautiful art on a safer basis in this country, that we tender the foregoing advice.

Let us turn now to an examination of the display of horology in the International Exhibition, and here indeed there is some ground for gratulation. If that display be not so extensive as might be wished it is at least creditable and choice. One of the principal exhibitors is Mr. F. Dent, of Charing-cross, whose name has long been honourably known in the horological world. Mr. Dent does not display in the north-east gallery any specimens of the larger kinds of clocks for the manufacture of which his house has attained celebrity, but of the smaller and portable description of time-keepers, he has exhibited several. One of them, and which is in all respects of a model character, is a chronometer clock fitted with a patent balance, which accommodates itself to extremes of temperature and thus makes the instrument independent of climatic changes. This rather remarkable exemplification of the talent of a London manufacturer chimes the quarter hours upon eight bells, is furnished with a perpetual calendar showing at a glance the days of the week and month, and phases of the moon, &c., the equation, and the bissextile. It is contained in a case of gilt bronze and glass, and as we have said, it in every way reflects credit upon its manufacturer. Of watches the same house has an excellent show of almost every kind. Perhaps the most noteworthy is what is termed their "gold observation watch." This is intended for a variety of scientific purposes, and among them the timing the transit of a star, or the phase of an eclipse; operations wherein the most delicate accuracy is required, and where the exact periods of commencement, rates of progress, and terminations must, if the observations are to have really practical value, be ascertained and registered with mathematical precision. In the observation watch the effect is obtained by having the centre seconds-hand double, one part overlying the other so as to give the appearance of a single hand in ordinary action. By pressing a knob at the pendant on commencing an observation the lower hand is instantly stopped, but the upper hand will continue in action until, as the moment of observation comes, the knob is pressed a second time. Both parts of the seconds-hand then become stationary, and the exact interval of time of observation is seen registed on the dial. The common action of the watch is not at all interfered with by the process just described. It continues going throughout, and by pressing the knob a third time the two parts of the seconds-hand reunite themselves and fly to the nearest point to correspond with the minute. For astronomical, as well as for many purposes in connexion with mechanical science, the observation watch of Mr. Dent seems to us to be admirably adapted. A gold hunting watch, also shown, posesses some peculiarities which make it worthy of notice. This is so constructed as to go two days after winding, and the time may be felt by it in the dark, or by one who is deaf and blind! A compensation balance of perfectly new construction, and which has several advantages to recommend it to the notice of the horologist, together with other excellent specimens of ingenuity and chaste ornamentation, go to make Mr. Dent's stand at once instructive and attractive.

Mr. Frodsham, of 84, Strand, who has obtained many medals for the excellent chronometers he has produced, and whose name in this particular department ranks deservedly very high, exhibits in the north-east gallery a number of clocks and watches, all of which are distinguished by their own especial characteristics. Mr. Frodsham is an inventor of no mean attainments, and one of those horologists who, imbued with a love of his art, joins with them great mechanical aptitude. It has been too much the fashion among his brethren to cleave to old forms and practices, but Mr. Frodsham, on the contrary, is ever on the alert for the creation of new combinations, and desirous of revivifying horology by injecting into its veins, so to speak, some of the life-blood of mechanical activity which circulates elsewhere. The double compound micrometic equation balance, invented by this gentleman, as well as the differential balance, also the result of his skill, are sufficient to distinguish him from the old-school horologists, whose too careful nursing has almost suffocated horology. It is not possible for us to specify all the timekeepers and parts of timekeepers shown by Mr. Frodsham. It would be unjust, nevertheless, not to mention that he has devised a new standard to facilitate universally the measurement of watches, as well as a new system of nomenclature for chronometer and watch-making. Better had it fared with the arts just named, had they numbered among their disciples more of the original-minded class of men, to which Mr. Frodsham belongs.

To Mr. Hislop, of 108, St. John-street-road, London, belongs the merit of exhibiting an admirable standard, or observatory clock, showing mean and sideral time. This, besides being an illustration of excellent workmanship, in a mechanical point of view, is so contrived as to obviate the necessity of reducing, by calculation, a sideral observation to mean time, and *vice versa*. Mr. Hislop appears to be aware of the importance of combining lowness of price with accuracy, which point, as we have said preliminarily, is of the very last importance in the emulative contest between this and other countries. As a matter of course, Clerkenwell figures extensively in other directions than that in which Mr. Hislop's clock represents it; and to Mr. Edward Danist Johnson, of 9, Wilmington-square, the public are indebted for many excellent examples of the arts of which he is so excellent an exponent. The surveying chronometer of this gentleman is so useful an instrument to the scientific man, that it would be wrong to omit reference to it here. It is so contrived as to be "portable in the pocket, as well as suitable to the navigation of a ship." None of the interesting collection of articles exhibited by Mr. Johnson have been made at unnatural expense for the sake of show, but each is a fair representation of his ordinary work; and there is no denying that that ordinary work is exceedingly well done. In a much larger way the Messrs. J. Smith and Sons, of St. John-square, Clerkenwell, are exhibitors. Their selection consists mainly of church, turret, and house clocks, all having their special and distinctive qualifications. One eight-day turret clock deposited by this firm, is the counterpart of that made by them for the government department of science and art at South Kensington. The construction is good and the workmanship excellent.

White, of 20, Cockspur-street, Pall-mall, has a rather extensive, and in some respects remarkable, display of horological instruments. Foremost among them may be mentioned a monthly astronomical clock of somewhat peculiar construction, and excellent workmanship. This is fitted with a mercurial compensation balance, and pallets jewelled with sapphires. To all appearance it is well calculated for its purpose, and it demonstrates the state of perfection to which time-measurers have been brought in this country. A series of chronometers is also shown, of various degrees of ornamentation, but all exhibiting the same symptoms of precision. The design of one of these is admirable. It has a gilt metal case, with chased columns and enriched mouldings, and is surmounted by the figure of a lion, also chased. This design is, we believe, registered, and it certainly deserves that privilege. A Gothic hall clock claims especial notice, and is a favourable specimen of the work of the same maker. There is a sumptuousness and elaboration about it which, no doubt, will recommend it to the attention of those whose

pockets are sufficiently furnished to enable them to compass its purchase. It is well suited for the hall of a nobleman's mansion, and certainly would not be out of place in one of the richly-decorated chambers of the legislation palace at Westminster. It is an eight-day time keeper in carved oak case, with columns, roof, crockets, finials, crestings, and panels in polished brass.

Of a less pretentious, yet exceedingly chaste and elegant appearance, is an eight-day clock made by Mr. White. It is of the character known as three part quarter, chiming the quarters on four bell springs, and striking the hours on larger bell springs, for the sake of increasing the volume of tone. This is encased in black wood, with chased gilt metal mouldings, the cornices being supported by variegated emblematical figures, representing the four seasons; an eagle perched on a rock, and in the act of attacking a snake beneath it, forms an admirable finish to the whole. We have by no means exhausted the list of clocks exhibited on this stand, all of which have their special incitements to attention, and most of them to commendation. In the way of watches, too, there is a profuse display. Many of these are "keyless," and one of them in particular, of the description known as a "hunting repeater," is noteworthy on account of its beautiful design, and that of the appendages pertaining to it. It is of gold, with duplex movement and compensation balance, the case being ornamented with representations of lilies of the valley. The leaves of these are formed of green enamel, and the flowers of diamonds. The chain and brooch attached to it are of the same style of ornamentation, and on the whole it forms one of the most exquisite specimens of watch work which has fallen under our observation.

Benson, of Ludgate-hill, is not behind-hand in his exhibition in the north-east gallery, although it is in other and more conspicuous parts of the building that his greatest works are to be seen. Perhaps the cheapest exemplification of horological workmanship, whether within or without Captain Fowkes' edifice, is the "everlasting shilling silent clock" of Capt. H. B. Coathupe, of Abingdon-street, Kensington. This cannot be called a *striking* example of the march of economy, but it certainly gives quiet evidence of that march, and does away with the excuse which prevents many persons from possessing time measurers, namely, their great cost.

Losada, of 115, Regent-street, and Howell, James, and Co., of 5, 7, and 9, in the same street, are extensive exhibitors of clocks, watches, marine chronometers, and astronomical pendulums. Most of these are very favourable exponents of the mechanical abilities and scientific skill of their respective manufacturers. It is impossible for us, however, to particularize them with minuteness, because to do so would be to absorb much more space than can be spared for such purpose. It would be an act of injustice to pass over without the commendation it demands, an English skeleton clock, shown by Thomson and Profaze, of 25, New Bond-street, who also show a variety of watches, clocks, time-pieces, "tell-tales," and jewellery. The clock to which we would especially refer as an instance of the blending, most successfully, art and mechanical manipulation, by the firm in question, is, as we have said, of that kind known by the name "skeleton." The clock itself is supported by two figures, exquisitely modelled and emblematic of day and night. Two other figures, one above and the other below, represent dawn and twilight. Day and night are poised upon the heads of dolphins, and the whole is supported on a stand in harmony with the general design.

Taking the Horological Department of the International Exhibition in its entirety, it must be admitted, we think, that it is highly creditable to those who have contributed to it. Still there are unmistakable signs, in the absence of specimens from the workshops of certain celebrated horologists, of the apathy which has operated so prejudicially for the interests generally of the professors of horology in England. There is no country in the world where the value of time, and the absolute necessity of punctuality in all engagements, are so fully appreciated as they are in the United Kingdom. So also is there, as has been above stated, no other country where so much practical and mechanical talent exists; why, then, should we not attain to the same amount of superiority in horology which has been reached in other branches of industry? The Conservatory of Arts and Sciences in Paris has one portion of it devoted to the illustration of French horological art, and assuredly it is not one of the least interesting features of it. We trust that when another assemblage of the fruits and flowers of the world's industry shall be consummated in our own vast conservatory at South Kensington, some riper and richer, as well as more numerous, examples of those fruits and flowers may be found in the horological section of it than are now visible therein. The great majority of exhibitors now are manufacturers established in London. Hereafter we shall be glad to congratulate some of our provincial friends upon their triumphs.

THE WHITWORTH AND HORSFALL EXPERIMENTS AT SHOEBURYNESS.

A detailed and accurate account from our special reporter of the experiments which took place at Shoeburyness on Thursday, the 25th September, reached us too late for insertion in our last number. Of these important and interesting trials of guns and projectiles, the proceedings and the results are in the main correctly reported in the *Times*. We do not, therefore, print our report *in extenso*, but we will correct the inaccuracies and supply the omissions of the *Times* report, which evidently was written with a strong *pro*-Armstrong and *anti*-Horsfall bias. In these nationally-important and costly experiments let us have the truth. Government most unwisely suppressed the report of the Iron Plate Committee, and thus withholds from the public a mass of valuable information which might assist inventors in improving our national defences. In addition to the usual assemblage of military and naval officers, Government officials, engineers, ship-builders, iron and gun manufacturers, there was on the ground a great number of foreigners, including agents of the French, Spanish, Prussian, and Danish Governments. It is, then, a farce on the part of Government to refuse to publish official reports of ordnance experiments on the plea of secresy, and it becomes the duty of the independent press to give a correct account of the results obtained. In the columns of that great authority, *The Times*, it would be in vain to look for a truthful description of Ordnance or Admiralty experiments. The reporter of that journal is the exponent of the views and wishes of the departments which give him access to those sources of information from which its pretentious, and not always veracious military and naval intelligence is concocted. The subserviency to official policy, and the spirit of partizanship which characterize those reports as a rule, were never more strongly exemplified than on this occasion.

The 120-pounder Whitworth gun, which at 600 yards, and with charges of 23 and 25 pounds of powder, produced destructive effects, which the 150-pounder Armstrong with a charge of 50-pounds could not equal, is coolly described by our contemporary in terms which would lead the public to suppose that it is an Armstrong gun, simply with the addition of Whitworth's hexagonal rifling. By this artifice of language, a great part of the extraordinary merit of the gun is claimed for Sir William. But, in point of fact there is no adaptation of his system in the construction of this now famous piece of ordance, except the partial application of the coil principle, which is not Sir William's invention, and which Mr. Whitworth is so far from adopting that, as it is well known, the very basis and essential principle of his mode of constructing guns is *homogeneous* iron, in the manufacture of which he has introduced further improvements, rendering it a far more suitable and economical material for guns than the so-called Armstrong coil. In the formation of the breach and other essential parts the construction differs entirely from the Armstrong plan, so that it is too bad to rob a successful and triumphant inventor of any part of his merit in order to bolster up the reputation of an amateur artillerist, who has signally failed in his attempts to produce a serviceable naval gun, although backed by the enormous resources and influence of the British Government. It would be amusing, if the results were not so costly to the nation, to contrast the language of the *Times'* reporter, inspired by official authority, in describing the Armstrong gun and projectile at two different periods. In the autumn of last and the early spring of this year, the country was congratulated on the possession of the most formidable ordnance in the world, in the form of the Armstrong Gun, whose destructive effects no armour plate, it was said, could resist, and now it is admitted that to penetrate an iron ship "The Armstrong is out of the question." In this way, by boasting paragraphs in newspapers, echoed and confirmed by bland secretaries, parliament and the people are mystified and deceived.

Nothing can be more unfair or untrue than the description given in the *Times* of the results of the practice with the Horsfall gun. For the purpose of enabling our readers to perceive the gross partiality and misrepresentation of the report in that journal, we copy the short notice with which the Mersey Monster is summarily disposed of, as being too contemptible for further observation, and shall contrast it with our own reporter's account, for the accuracy of which we appeal to the numerous spectators present at the experiments, to the artillery officers and men who laid and fired the gun, and to the evidence of the target itself, as it still stands at Shoeburyness:—"The "trials were continued with the Horsfall gun "at 800 yards against the uninjured plates of "the same target. The immense difference "between the powers of a smooth-bore and a "rifled gun, both as to accuracy and force of "its projectile, then at once became apparent. "The first shot was fired from the Horsfall "with 74 lbs. of powder, and a 275-lb. round "shot struck in front at some 10 or 12 feet to "the left of the target, which it missed alto- "gether. The gun was *re-laid again;* the shot "struck the ground about 40 feet in front of "the mark, ricochetting with a slight rise, and "striking full on an uninjured plate. In this "case it smashed an immense hole, shattered "the teak, and fractured the inner skin, leav- "ing all the elements of a fearful leak, as Mr,

"Whitworth's first shot had done, but, like "that also, not going quite through. The "third shot again missed the target entirely, "striking wide of the mark, and the fourth "and last only just saved the now sadly-dimi-"nished reputation of the gun, by hitting the "extreme uppermost corner of the target, the "metal of which it smashed. The failure of "this gun at this range was, therefore, as satis-"factorily settled as the success of Mr. Whit-"worth's, and the trials were discontinued."

That is the report of the *Times*. The following is extracted from our own :—

The important feature of the day's experiments was the trial of heavy ordnance at long range against the section of an armour-plated iron ship. For the purpose of instituting a fair comparison with experiments at short range, the target was precisely similar to the "Warrior" section, which had been so frequently fired at with Armstrong and 68-pounder guns at 200 yards, but it was of smaller dimensions, being 12 feet long and 10 feet high, without a port, whilst the original 'Warrior' target was of the same height, and 20 feet in length, with a port in the centre. The guns employed for the attack were the celebrated Horsfall 280-pounder, smooth bore, carrying a 13 inch round cast iron shot, with a charge of 75 lbs., and the Whitworth 120-pounder rifled naval gun, carrying a 6-inch flat-headed cylinder, with hexagonal rifling, 13½ inches in length, as a solid shot, and 17 inches in length as a shell, with a charge of 23 lbs. for the former, and 25 lbs. for the latter, the weight of the projectile being 131 lbs. in both cases. The Whitworth gun was trained at 600 yards, the Horsfall at 800 yards. In estimating the effect and accuracy of the firing, the length of range must be kept in view. In former experiments with Armstrongs and 68-pounders the range was only 200 yards. On every occasion of short-range trial they were favoured with fine clear weather, but this day's proceedings were inaugurated with a dense fog, which for some time made it doubtful whether the experiments could be carried out at all, and during the whole day the weather was so hazy that at 800 yards the target was barely visible. This state of the atmosphere materially affected the aim of the Mersey gun, which was 200 yards more distant from the target than the Whitworth. The former was under another serious disadvantage in being badly sighted, whilst the sighting of the Whitworth is so perfect a mechanical contrivance that a miss is almost impossible. These circumstances are to be taken into account in comparing the accuracy of the practice with the two guns. Before commencing the experiments a pioneer shot was fired from each gun to obtain the elevation, and did not hit the target. By means of a frame a few feet in front of the target, with fine copper wire stretched across it horizontally, the striking velocity of the projectiles was ascertained with great accuracy.

The target is covered with three 4½-inch plates, each 3 ft. 4 in. wide, and about 12 ft. long, backed with 18 in. of teak secured to the skin and frames of an iron ship.

The Whitworth solid bolt hit the middle plate fair about 3 ft. from the left butt, penetrated the 4½-inch plate and half the thickness of the wood backing, in which it buried itself, being spent before it reached the iron skin plate, but the projectile force transmitted through the wood burst open the skin plate, and broke two iron frames, making a ragged fracture 12 to 15 in. square. The hole in the armour plate, 8 in. in diameter, was perfectly round, and clean cut as if drilled with a tool. This effect is to be attributed to the rapid rotary motion of the rifled projectile combined with its onward velocity, which, at the moment of impact, was 1,284 ft. in a second.

The Whitworth shell struck the same plate at the right hand corner 12 to 15 in. from the butt and the bottom joint. It penetrated like the solid shot through the armour plate, and exploded in the teak backing. The force of the explosion burst through the skin, producing an aperture 9 in. in diameter, and broke the outer frame, but no splinters passed through the target. The impact being close to the outer edge, the explosive force expended itself chiefly in blowing out sideways the timber backing, which protruded 8 or 9 in. from the end of the target. The cover of the shell passed out through the wood in that direction, and was pitched up 20 or 30 yards to the right. The hole in the plate was rather larger, and not so perfectly round or smooth as that produced by the solid shot, and the plate was cracked in three places around the hole.

After the trial shot to regulate the range, the first discharge from the Mersey gun hit the target on the right, at the joint of the middle and bottom plates, making a terrific jagged fracture through both plates measuring more than 2 ft. in diameter, but like the Whitworth bolts it failed to penetrate the target, and lodged itself in broken fragments in the teak backing. The transmitted force burst open the skin plate over a surface three or four times larger than the fracture caused by the Whitworth projectile, and completely smashed a frame into pieces. This shot grazed the ground a few feet before the target and passed under the wires, so that its velocity was not ascertained, but as the striking velocity of another shot was afterwards obtained, it is as well to mention here that it was 1,285 ft., with the remark that no doubt the destructive effects of the first shot would have been much greater if by ricochetting it had not lost part of its projectile force. The next shot was a miss, which the officer who pointed the gun accounted for by what he termed the "miserable mode of sighting," which in the hazy state of the atmosphere made a good aim impossible. The third shot hit the upper left corner of the top plate and smashed great pieces out of it, leaving a fracture 3 ft. long and 2 ft. wide. Owing to the want of sufficient support at the back close to the edges, no inference can be drawn from this result, which indicate the correctness of what has been frequently shown in target trials, that the effects depend a great deal on the nature of the backing.

The day was now so far advanced that the experiments were brought to a close, but as the steely texture of the broken iron of the plates exhibited symptoms of inferior quality, a 68-pounder was fired at one of the plates at 200 yards, and with the same service charge which was the standard test of quality at former experiments. The result was an indentation in the 4½ in. plate of 4·05 in., together with extensive disintegration of the iron in a ring of cracks round the edges. Compared with similar trials on the Warrior and Iron Plate Committee targets, which gave a maximum indentation of 3·5, and an average under three inches, these results prove the iron of the plates on this occasion to be much inferior in quality. They were stated to be remanents of the "Black Prince," constructed by Messrs. Napier & Co., of Glasgow, and bear the mark of Messrs. Rigby, of Parkgate Works, near that city. It is to be hoped that the armour plates of the "Black Prince" are superior in quality to the specimens experimented upon.

THE MANUFACTURE OF GUNPOWDER.*

(Concluded from page 191.)

On the "Cost of Powder" we are told "secondary, and only secondary, to the quality of "powder is the cost. Good powder, made "with a small outlay, is the point required "from the agent by the Government; but "much of the cost depends on the price of the "crude materials. The cost of the nitre alone "is one-half the expense of the powder. The "English service powders cost £5 upwards for "the 100 lbs. The best sporting powders sell "in London for from £10 to £15 the 100 lbs. "Blasting powder is sold by dealers from "50s. to 75s. per 100 lbs."

Treating of the motive power, we are informed that "every description has been em-"ployed in the mills." Running water is considered the best, and steam the worst, owing to the danger necessarily attending this manufacture. In India bullocks are employed.

The powder being finished is submitted to the hygrometric proof, to test its power of absorption, as upon this depends its loss of strength by storage, especially in humid climates or situations.

"If the powder did not continue of one uni-"form strength, or in some known ratio of a "conserved standard, all the science, expe-"rience, and practice of the artillery would be "useless. A standard of strength must be "established, and some mode settled as to "measuring it. The present authorized mode "in India is a Gomer mortar of 8 in. diameter, "8 cwt. 1 qr. in weight, 1 ft. 4, 3-10th in. in "length of bore. The shot, a ball of solid "iron of 68 lbs. weight, 7·85 in. in diameter, "charge of powder 2 oz., elevation 45°, proof "distance for the shot to be thrown 63 yards; "if below this range the powder is rejected. "A decrease of half a tenth of an inch in the "diameter of the ball, or in increase of the "same quantity in the diameter in the mortar, "will render both unserviceable for proof, as "will also an enlargement of the vent of half "a tenth of an inch." This is the first proof. Then at the close of the practice season, some of the powder of the previous year is taken indiscriminately and tried with every available piece of ordnance. This is the Commandant of artillery's proof. There is a third severe test carried on in each of the Presidencies with powder from all these. There are the hot and wet weather proofs in which the powder is subjected to a variety of experiments, and all the results are carefully tabulated. From a mass of most important information we extract the following :—

"*To analyze powder.* To 100 grains add 600 "grains more or less of distilled water, then "filter the solution through clean filtering "paper. The water is then to be evaporated "over a spirit lamp, the dried residue will be "the proportion of the saltpetre. The mass "collected on the filtering paper consists of "the sulphur and charcoal combined. If this "residue be placed in a copper dish, and "heated to above 240 degs., the sulphur will "disengage itself in fumes, and leave the char-"coal. If the saltpetre of any quantity of "gunpowder to be examined be not pure, by "dropping a few drops of the solution of "nitrate of silver into the clear solution that "has drained through the paper filter, any "impurity of chloride of salts will be indicated "by the clear solution becoming cloudy; the "proportion of impurity may be detected by "chemical tests."

"The experiments on Mortars" is a chapter of great importance, and the tables and mathematical illustrations on experiments, with charges at various ranges—the effects of reducing the weight of ball—windage and recoil, will well repay all interested in artillery pratice, or knowledge, for careful study, as will also the succeeding chapter on musketry experiments. The *Appendix*, which occupies one-third of the volume, contains much varied information on the subject of gunpowder, among the matter of which it treats are "experiments "on varied proportions of ingredients of gun-"powder;" "chemical effects of combustion in "close chambers;" gun cotton, and other sub-

* Sketch of the Mode of Manufacturing Gunpowder at the Ishapore Mills, in Bengal, with a Record of the Experiments carried on to ascertain the value of charge, windage, vent and weight, &c., in mortars and muskets; also Reports on the various Proofs of Powder, by Colonel William Anderson, C.B., late Agent at Ishapore, with Notes and Additions by Lieutenant-Colonel Parlby, Retired Bengal Artillery. Weale. London: 1862.

"stitutes for gunpowder; "accidents;" "modern improvements in artillery;" the "manufacture of war rockets, &c."

The chapter on modern improvements in artillery, &c., possesses peculiar interest at the present time, and is the production of the editor. It deserves to be extensively read and studied. Its author takes a retrospect of these improvements, and justly observes, "that as an entire change has been effected, or "is now taking place, in almost every department of the science of war, those nations "that are neglectful, or remain unprepared in "this advance—if unfortunately they become "involved in hostilities—must suffer the "evil consequences of such neglect. Those "who depend upon the traction of horses for "conveyance, cannot attempt to compete "with the railroad speed of the present day; "neither can the less powerful cannon and "fire-arms of comparatively recent date be "now brought into the field with any chance "of success; and, moreover, *the stream of "advance and improvement is yet moving on!*

"In naval and land battles, therefore, as "well as in our system of fortification, great "changes must necessarily take place, and it "requires no argument to prove that, to be "effective against iron-plated ships, we must "have more powerful ordnance, and probably "abandon the old plan of placing guns on "ramparts to fire through embrasures, by "which defective plan ships can run up close "to the batteries, exposed to the fire of only a "fraction of the number of guns planted upon "them. The ramparts should be plain, and "the cannon defended by moving cupolas, or "shields, with proper traverses between each "gun, to prevent the effects of enfilade, and to "protect the unemployed gunners and those "that serve the ammunition, and only high "enough for those purposes. Thus the guns "will be '*en barbette;*' and by having no "limitation as to their lateral range, can bring "the whole force of the artillery into play on "any front attacked by land or sea."

There are now at least four serious questions, the subjects of controversy and experiment, relating to artillery and fire-arms:—

1. Whether cannon should be of solid metal, cast or otherwise; or whether they should be built up, or a combination of several parts?
2. Whether to be rifled or smooth bore?
3. Whether they should be muzzle or breech-loading?
4. The best form of projectile.

These *vexatæ questiones* are ably discussed, and cannot fail to impart great additional value to this elaborate and important work. The work is in large octavo, and contains 303 pages of large type. The paper and printing are excellent, and the appearance of the volume very attractive, which are great desiderata too often overlooked in scientific treatises.

We are sure the book will be carefully studied in foreign countries by all interested in the science of war. This has been anticipated by the gallant editor, who has printed on the fly-leaf a list of no fewer than thirty-eight cities, in foreign countries and the colonies, where the volume can be obtained. We commend the book to the serious consideration of our own countrymen, assuring them that it is, in our judgment, on the subjects of which it treats, *the* book for the times.

THE WRECK REGISTER AND CHART FOR 1861.

(With the Chart.)

SHAKESPEARE compares England to a fortress, and the channel to a moat; but if he saw the leviathan steamers now coming up that channel, he would be the first to acknowledge that the comparison did not hold good in the present day. We do not now look upon the sea as itself giving us a defence; it is only our chief medium of defence. But it is now, as in the days of Drake, our great commercial highway and source of our strength, girdling us, if it do not guard us, and bearing into our havens all the products of the known globe. All who leave us or approach us must do so by this great highway, which carries on its bosom in the course of one year alone, to and from our own ports, no less than 267,770 ships, including repeated voyages, and which ships have probably been manned by 1,600,000 souls.

Such is the field of operations over which these dry statistics of the Board of Trade carry us. As usual, they have been most ably drawn up and collated in every possible form. Yet on nearly every page of this Register these startling facts, in admonitory terms, face us, that 1,494 shipwrecks occurred on British shores last year, from which 884 people are known to have perished.

The number of wrecks last year has unfortunately exceeded the number during any of the preceding nine years, and it is 260 in excess of the annual average of the last six years.

It is a lamentable fact that shipwrecks on our coasts have been of late years on the increase. Thus, during the last seven years, we find the following account:—In 1855, 1,141; 1856, 1,153; 1857, 1,143; 1858, 1,170; 1859, 1,416; 1860, 1,379; 1861, 1,494!

The accompanying Wreck Chart clearly shows the spot where each casualty occurred, and the number of lives lost by it.

We are told that this great increase of disasters in 1861 was owing to the fearful gales of January, February, and November of that year, when 842 wrecks took place, principally amongst our rotten collier class of vessels. Gales, even of a moderate character, are always destructive to these ships; or, in other words, they are doomed to certain destruction under circumstances in which a ship, if seaworthy, and properly manned and found, ought to be able to keep the sea. The best harbours of refuge in the world would not, therefore, prevent a tithe of these disasters, which unfortunately too often occur where neither the lifeboat nor the rocket apparatus is available to succour their unfortunate crews.

We regret to find that the number of collisions is also on the increase. No calamity is more fearful than that of a collision at sea during a dark, stormy night. Its destructive effects are instantaneous, and frequently a large number of persons go down with either ship. The collisions in British waters were in 1859, 349; in 1860, 298; and in 1861, 323! But what is very remarkable in regard to these fearful collisions is the fact that, during the past six years, 750 collisions have taken place in clear and fine weather, 378 from bad look-out, 264 from neglect of rule of road at sea, and 61 from actual want of seamanship, the gross total of collisions during the past six years having been 1,864.

A natural sequence of the increase of vessels wrecked is the increase of precious lives lost. The number of persons who thus lost their lives in 1861 was, as previously stated, 884; while in 1860 it was only 536.

This, let it be remembered, is not a casual loss. It is a continual if not an ever-increasing one. The drain on our sailors and fishermen goes on year after year, notwithstanding all the benevolent and strenuous efforts made at the present day to stay the ravage. The sea is dreadfully exacting in its demands; and season after season, when the equinoctial gales blow, when the winter sets in, or when the summer, as our last one did, yields to the temporary but powerful influence of storms, our shores are converted into altars, on which the ocean offers his victims. It is unlikely that we shall ever effectually obtain the mastery over the waves; but, even at this moment, we are able to contend successfully with them in their blind efforts to swallow up life against our endeavours to save. If, for instance, during 1861, 884 people lost their lives on our coasts by shipwreck, yet no less than 4,624 were directly saved from such a fate. The whole number makes up a considerable fleet of seamen—men for whom, perhaps, in moments of national emergency, we would give any money—and many of these were preserved under the most perilous circumstances by the craft of the National Lifeboat Institution.

The total number of casualties in two years is 2,873, out of which 1,660, or about seven-twelfths of the whole, happened to ships of the collier class—a fearful disproportion, and calling loudly for a thorough and searching investigation.

The following table distinguishes clearly the description and tonnage of the ships lost during the past year:—

	Vessels.
Vessels under 50 Tons	228
50 and under 100 ,,	434
100 ,, 300 ,,	639
300 ,, 600 ,,	135
600 ,, 900 ,,	31
900 ,, 1,200 ,,	18
1,200 and upwards	5
Unknown	4
Total	1,494

Let us briefly analyze the causes of this great destruction of property. We find that 10 wrecks took place in a perfectly still sea, 14 in light airs, 51 in light breezes, 43 in gentle breezes, 103 in moderate breezes, 171 in fresh breezes, 149 in strong breezes, 66 in moderate gales, 124 in fresh gales, 230 in strong gales, 311 in whole gales, 102 in storms, 52 in hurricanes, and 68 in unknown and variable weather. Total wrecks 1,494. Of these 619 took place amongst ships in the home and coasting trade, commanded by men not required by law to have certificates of competency; 266 wrecks only occurred amongst vessels in the home trade, commanded by masters holding certificates of service; so that the rivalry between ignorance and knowledge is an unequal one, as it ever has been and ever will be.

The estimated loss on these 1,494 wrecks is upwards of one million sterling. But who can estimate the loss of the valuable lives who also thus perished with the ships! Many a widow and orphan in our seaport towns and fishing villages will tell us how severely they have felt their bereavement!

The accompanying roll of the loss of life on British shores and waters during the past twelve years will be perused with melancholy interest. The districts are thus classified:—

	Lives lost.
Farn Islands to Flamborough Head	670
Flamborough Head to the North Foreland	1,068
North Foreland to St. Catherine's Point	514
St. Catherine's Point to Start Point	82
Start Point to the Land's End	460
Land's End to Hartland Point, including Scilly	353
Hartland Point to St. David's Head	473
St. David's Head and Carnsore Point to Lambay Island and Skerries, Anglesey	969
Skerries and Lambay to Fair Head and Mull of Cantire	1,597
Cape Wrath to Buchan Ness	257
Buchan Ness to Farn Islands	280
All other parts of the coast	922
Total lives lost	7,645

It is thus seen that the most serious wrecks, as was urged in parliament last session, do not happen on the north-east coast of England, but in those seas and channels mostly frequented by large foreign-going ships. This is a matter deserving earnest public attention. Some hundred thousands of pounds judiciously laid out in improving our great natural harbours of refuge, would, we think, be attended with the greatest possible benefit.

Again this fearful list tells us in legible terms that man cannot avert the storm, nor prevent the occurrence of wreck and violent death at sea. The proudest vessels that he builds of wood and iron are but as large straws before the winds of heaven. A breath can dash them on the shore, and they perish in their pride, and our vanity is

humbled. We may never hope to rise superior to every storm or cause of wreck. It is our duty, however, to strive for safety—to continue to wrestle hard with danger—to confine disaster and death within the narrowest limits which human efforts can impose upon them.

How happily, then, the efforts of the National Lifeboat Institution, the Board of Trade, and kindred bodies on the coast have been blessed during the past six years! During that period alone 16,119 persons have been saved from shipwrecks by means of the lifeboats, the life-preserving apparatus, shore-boats, and other appliances, as the annexed list shows:—

	Lives saved.
1856	2,243
1857	1,668
1858	1,555
1859	2,332
1860	3,697
1861	4,624
	16,119

He must be less than man who can read unmoved and without a glow of admiration the account of such services and of those given in that Institution's report. Take the rescue of the crew of the brig "Sisters," of Whitby, on the 26th February last. It will serve as a suitable illustration of the dangers that have to be encountered by the skill, courage, and endurance that are needed of the brave fellows who man the society's life-saving fleet:—

"The 'Sisters' was laden with coals, and had been driven on shore on the South Barber Sand, off Caistor. Her signals of distress having been seen from the beach, the Caistor boatmen proceeded to launch the lifeboat there through a tremendous surf, the wind blowing a heavy gale from the east at the time, and the night being intensely dark. Under these difficult circumstances, although more than 100 persons were engaged in helping to launch the boat, an hour elapsed before she could be got off the beach and warped to the hauling-off anchor laid down outside the surf. Sail being then made on her, she worked to windward to the scene of the wreck, where the anchor being let go, she was veered down, but owing to the darkness and the fearful sea breaking over the vessel, it then took an hour to get the crew of nine men into the boat, and that at very great risk, as the lifeboat was often lifted by the sea high above the vessel's sides, and several times dashed violently against her and on the sand, thereby incurring considerable damage; also losing one hundred fathoms of her rope gear, which had to be cut away on hauling off from the wreck. It was indeed life for life, but humanity prevailed in the courageous encounter, and the wrecked crew were ultimately got safely in, and landed through a heavy surf. Forty-five pounds were paid by the Institution for this service, viz., £40 to the 20 men forming the lifeboat's crew, and £5 to the parties assisting to launch the lifeboat."

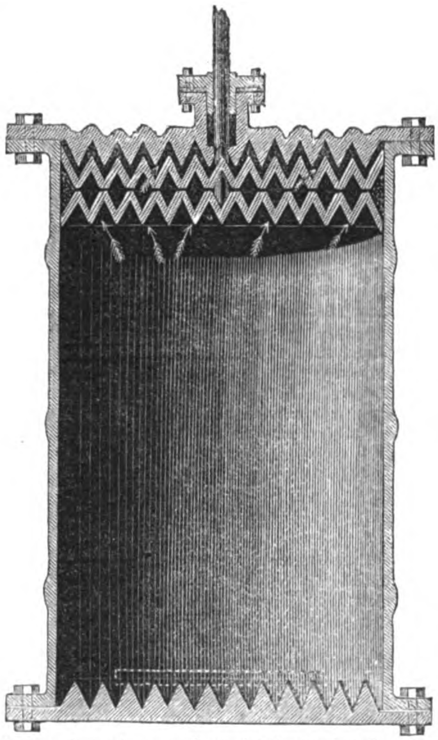
Englishmen in every part of the world may surely pause with pride over such chronicles of lifeboat services on our coast, as also over the reports of the cheerful liberality with which the National Lifeboat Institution is supported, to enable it to continue and extend with unabated vigour its merciful operations on our coasts.

We will recapitulate some of these beneficient gifts, and allude to the Society's operations.

Lord Chief Justice Erle, and the Corporation of London, and the Members of the Royal Thames and the Victoria Yacht Clubs, contributed liberally for the safety of the seamen. A citizen of Newcastle-on-Tyne, to whom a legacy of £19 had been left, passed it over, not to his own banker, but to that of the Institution. "N.L.," residing in Manchester, sent £250 to defray the cost of the Kirkcudbright lifeboat; and a stranger, "who would not give his name," left at the institution a bank note for £200. Mrs. E. Hope, carrying out the dying wishes of her husband, the Rev. F. W. Hope, gives £340 to buy a new lifeboat for Appledore, Devon. The ladies of Newbiggin realized for the funds £301 16s. by a bazaar; Mrs. Hartley and Miss Bertie Cator, promoting lifeboat funds, were enabled to raise six hundred guineas; Miss Burdett Coutts, in her exhaustless beneficence, gave the cost of the Plymouth and Silloth lifeboats; Mr. G. J. Fenwick, of Seaton Burn, contributed £250 to provide the Tynemouth lifeboat. Miss Brightwell, honouring her father, pays the cost of the Blakeney boat, and calls it after his name; and certain travellers in the smoking saloon of the North Kent Railway, bethinking them of the claims of the National Lifeboat Institution, extemporised a subscription to increase its resources. Even from Abo, in Finland, £50 is sent to the Institution in admiration of its services to the shipwrecked crews of all nations.

We have a list before us of the names of upwards of one hundred wrecks, from which, within the space of two years and a half, 726 lives were saved by the lifeboats of the Society. It is on this list—this trophy of success—that the committee of this Institution found their latest appeal. During that period its establishments on the coasts of the United Kingdom have cost £27,260. They have voted £2,458 as rewards to the crews of their life-boats, and £572 to those who, by shore-boats and other means, saved 562 shipwrecked persons, in addition to the above 726; making a total of 1,288 persons saved from a watery grave during the last two years and a half. Since its formation, the Institution has been instrumental, by its lifeboats and other means, in saving 12,680 lives; and having now 123 lifeboats under its management, it requires a large annual income to meet the demands upon its priceless services.

SYMONS' CYLINDER-COVERS AND ENDS.



A very ingenious and useful invention has just been patented by Mr. N. Symons, of Cambridge-street, N.W., which consists in serrating or corrugating the upper and lower surfaces of pistons commonly used in steam engines, for the purpose of increasing the superficial area without increasing the diameter of the cylinder. The above engraving illustrates a cylinder of the ordinary construction having the piston formed according to the above invention. The arrows indicate the action of the steam against the serrations. The cylinder-cover and end are correspondingly shaped, to enable the piston to complete the full stroke. According to the patent, every form of corrugations, indentations, or grooves is protected. The invention is equally applicable to valves and cylinders of other than steam-engines.

THE ASSOCIATION FOR THE PREVENTION OF STEAM BOILER EXPLOSIONS.

Chief Engineer's Monthly Report.

At the last ordinary Monthly Meeting of the Executive Committee of this association, held at the offices, 41, Corporation-street, Manchester, on Tuesday, September 30, 1862, Hugh Mason, Esq., vice-president, in the chair, Mr. L. E. Fletcher, chief engineer, presented his monthly report, of which the following is an abstract:—

"I am happy to be able again to report that no explosion has happened during the past month to any boiler under the inspection of this association, neither has the occurrence of any in other quarters come to my knowledge.

"During the past month there have been examined 263 engines and 451 boilers. Of the latter 15 have been examined specially, 6 internally, 72 thoroughly, and 358 externally; in addition to which 4 of these boilers have been tested by hydraulic pressure. The following defects have been found in the boilers examined:—Fracture, 8 (1 dangerous); corrosion, 49 (8 dangerous); safety-valves out of order, 3; water gauges ditto, 14; pressure gauges ditto, 4; feed apparatus ditto, 3; blow-off cocks ditto, 16 (1 dangerous); fusible plugs ditto, 5; deficiency of water, 1; blistered plates, 3 (1 dangerous). Total, 106 (11 dangerous). Boilers without glass water gauges, 5; without pressure gauges, 1; without blow-off cocks, 17; without back pressure valves, 25.

"Two boilers have recently been met with, neither of which was fitted with its own separate safety-valve, but both were dependent on a single one placed upon the steam pipe, the communication between which and each boiler was conditional on its junction valve being open, so that had the attendant at any time inadvertently left this valve screwed down—on getting up steam, for instance, on a change of boilers—the whole steam pressure must have been bottled up without chance of escape.

"Feed Back-Pressure Valves.

"Some of our members do not appear to be fully aware of the importance of fixing a feed back-pressure valve to each of their boilers, and therefore the following instance, lately met with, of the inconvenience arising from the want of them, may be given:—

"Four boilers, set side by side and connected together, were working under their ordinary circumstances, when one of them vomited its water through the feed pipe into the adjoining one, draining itself, and over-charging the other. The danger of this, if not immediately detected, with a fire in active operation, will at once be seen. It is, however, by no means an uncommon occurrence where back-pressure valves are omitted, especially where any thickening matter exists in the water, which tends to lift it and cause priming, under which circumstances the water has been found to rush backwards and forwards alternately between boilers working in connection. The back-pressure valve prevents this; the water from the feed pump operating underneath and raising it, while the pressure from the boiler operates on the top and closes it. Necessary as these valves are to the safety of boilers when working in a series, they should not be neglected in the case of those working singly, not only when fed by a pump, but also when fed direct from the waterworks main; in the first case, in order that the pump-valves may be accessible when steam is up, and in the second, that the reflux of hot water from the boiler may be prevented either on the bursting of the pipe or other cause. These valves should be placed immediately upon the shell of the boiler, and not at a distance from it, as is sometimes the case, since scalding might ensue should any joints break in the intervening length of pipe, while repair could not be effected without letting the pressure down. For the same reason the feed stop valve should not be interposed, which it too frequently is, between the back-pressure valve and the boiler, since a disarrangement of the stop valve may entail an entire stoppage, which had the feed back-pres-

sure valve been placed immediately upon the shell, could easily be rectified with steam up.

"In the construction of this valve care should be taken to limit its rise, for want of which simple precaution some of them have proved to be entirely useless, the water passing freely from one boiler to the other, as if the valve were not there. Its most convenient position is at the front end plate of the boiler, nearly on a level with the furnace crown. Its beat can then be heard at every stroke of the engine, and if a screwed spindle be added, so as to convert it into a combined feed stop an back-pressure valve, which is the best arrangement, then the feed can be regulated without leaving the furnaces.

"Blow-out Apparatus.

"A case of scalding has lately occurred in consequence of the failure of the blow-out apparatus of a boiler, which was, however, not under the inspection of this association.

"The manner in which blow-out taps are often strained with long levers in opening and closing, renders it a matter of surprise that fracture does not more frequently occur, and many have such inefficient arrangements for carrying off the waste water that it beats back with so much violence on the taps being opened that their use is quite dangerous. Enginemen are in this way but too frequently scalded severely, and our own inspectors sometimes meet with narrow escapes. Some taps are so inconveniently placed that the nut at the bottom of the plug is quite inaccessible, and thus becomes neglected, in consequence of which several cases have occurred of the plug being shot out by the force of the steam on being opened. Taps fitted with glands are safer as well as more convenient; they should, however, be made entirely of brass in the shell as well as in the plug, and be fitted with a suitable waste pipe. Those made of cast-iron in the shell, and brass in the plug are generally found to be inconvenient, and sometimes dangerous, on account of the unequal expansion of the two metals, from which it is frequently impossible to close them, when the boiler becomes robbed of its water, and the fires have to be drawn to prevent injury to the furnaces.

"The case in question, however, was somewhat peculiar, and the fracture did not arise from either of the above causes. The blow-out tap was attached to the boiler by a cast-iron elbow pipe, and this pipe broke short off without warning, while the boiler was at its regular work and the blow-out tap not being touched.

"The cause of this appeared to be as follows: —Boilers, as it has been previously stated in these reports, are too frequently considered to be in a state of rest when once set upon their brickwork bed; whereas, from the constant changes of temperature, and the consequent contraction and expansion that take place, not only in the boiler itself, but also in the brickwork, the whole is in a continual state of movement. It appears most probable that this action had in process of time induced a slight settlement of the boiler, and thus that a strain was brought upon the cast-iron elbow pipe, which being bound by the brickwork, consequently gave way. A torrent of hot water naturally ensued, which, unable to escape at the usual outlet, found its way into an adjoining building, where it partially flooded one of the floors, and two or three persons became scalded in consequence.

"Prevention of Incrustation.

"It may be stated in brief that the scum pipes for surface blowing out, which have been recommended from time to time for the prevention of incrustation in boilers, have now been adopted by several of the members, and have, for some time since, been in very successful operation. An early opportunity will shortly be taken of making more detailed reference to this subject; but, in the mean time, it may be stated that a drawing of the arrangement adopted lies at the office for the inspection of the members, and that full particulars, both of the details of construction and results of working, will be given on application.

"Hints to Members on Laying Down New Boilers.

"There is one branch of the service this association affords which the members do not avail themselves of as fully as they might—namely, that of consulting the records at the office before laying down new boilers or making alterations. Full particulars are kept, not only of the construction of the boilers under inspection, but also the results of their working; and a consultation of these would frequently save unnecessary outlay, prevent failures of one being repeated by others, and place at the command of each member the experience acquired by the inspection of the whole number of boilers under the charge of the association.

"L. E. FLETCHER,
"Chief Engineer."

AMERICAN INVENTIONS.

At a recent meeting of the Franklin Institute, Philadelphia, Mr. Howson, of the committee, on meetings, exhibited a military cap, the invention of W. F. Warburton, of that city. The edge of the cap is provided with a number of eye-lets or hooks, by which a detachable cap or havelock may be attached. A loose fold, forming a part of the cloth or covering of the cap, is arranged so as to conceal the hooks and eyes, the fold being retained in its position over them by elastic loops attached to the corners, and passing around the strap buttons.

Mr. Howson also exhibited an exceedingly well executed pair of bronzes, manufactured by Messrs. Warner, Miskey, and Merrill, of Philadelphia. The designs are copies, but the composition of the metal and the casting are the work of the above-named firm, who were the first in this country to manufacture heavy bronze work, one of their finest pieces being the bronze balustrade for the capitol at Washington.

Mr. H. also exhibited a musket, which, he remarked, was to all appearances similar to the many weapons of this class we every day see in the hands of our soldiers. The specimen, however, would be looked upon with unusual interest when they were informed that it was one of the first complete regulation muskets made in this city, and a specimen of the first one thousand muskets recently delivered to the Government by the manufacturers and contractors, the well-known firm of A. Jenks & Son, of Bridesburg. It had fallen to the lot of the exhibitor to examine minutely many modern fire-arms, both of American and European manufacture, and he could state that, as regards excellence of workmanship, neatness of finish, and superiority of material employed, the weapon could not be excelled.

Mr. Howson also stated that few could imagine, without investigating the subject of manufacturing fire-arms, the extent of the enterprise undertaken by the Messrs. Jenks. In order that some idea of the amount of labour and thought demanded in establishing a manufactory such as that of Messrs. Jenks, Mr. Howson produced a small pistol, known as Sharps' four-shooter, and stated that a witness had recently sworn that, to manufacture such a weapon profitably, an outlay of 100,000 dollars was necessary.

On comparing the two weapons, the members could form some judgment of the enormous amount of capital required and the ingenuity and forethought exercised by the Messrs. Jenks in perfecting, during little more than one year, the machinery and apparatus required to manufacture the weapon exhibited, at a price remunerative to themselves, and with the rapidity which the present emergencies of the Government demanded.

PATERSON'S IMPROVEMENTS IN RE-BURNING ANIMAL CHARCOAL.

These improvements, patented by Mr. Paterson, of the Middle Temple, relate to means or apparatus for re-burning animal charcoal. For this purpose the retorts, which are of a cylindrical form, may either revolve continuously in one direction, or partly in one direction, and then in the other; and instead of being placed with their axes in a horizontal direction, they are inclined, and they receive the charcoal to be re-burned at their higher ends through suitable channels; and then by the revolution of such retorts the contained matter will progressively traverse to the lower ends thereof, where there are vanes or cups, or other suitable means adapted to take up such matter, and discharge it into a receiver projecting inwards from such lower ends, and having a communication with the cooling apparatus.

Series of such retorts can be arranged to work together, each being caused to revolve, and being inclined from the feeding to the delivery end as stated, with the delivery end of the first discharging by a suitable way into the feeding end of the next, and so on with the succeeding retorts of the series.

The feed and discharge pipes are connected to the respective ends of the retorts in manner to admit of the retorts revolving. The charcoal from each retort, or from the last of a series of them, is conducted into suitable coolers before exposure to the atmosphere, and a jet or jets of water are employed to operate upon the external surfaces of the cooling chambers, or the passage or passages to them, to facilitate the cooling process. The means for lifting at the ends of the retorts may be separate, and operated by mechanical means.

The gas or vapour generated during the process is allowed to flow back and escape by the feed pipe, so as to avoid re-admixture with the manufactured or re-burned charcoal.

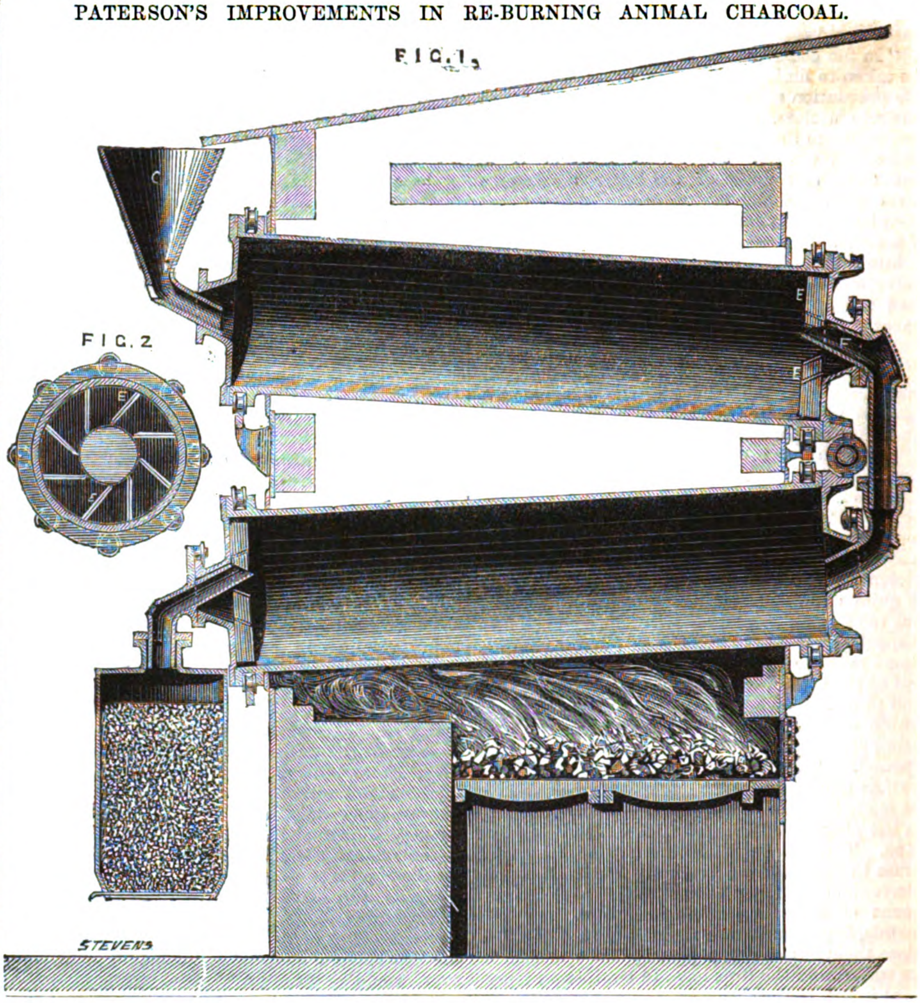
Fig. 1 of the above engravings shows a longitudinal section, and Fig. 2 a transverse sectional view of one set of retorts.

Two retorts are shown in a setting heated from the one fire-place as shown, but the number of retorts in the setting may be varied. It will be seen that each retort is set in a direction inclining from the feed to the discharge end. The upper surface or top plate of the kiln is formed by preference of cast iron, adapted to receive and support the charcoal to be operated upon; C is a hopper, in position to be readily supplied with charcoal from the top surface. This hopper is provided with a valve through which it discharges its contents into the pipe, and thence into the upper cylinder. The valve regulating the discharge from the hopper may be operated by a rod passing horizontally along the front of the kilns, and have a reciprocating motion given to it. The charcoal received by the passage G into the upper retort is, by the rotation of that retort, aided by its inclined position, progressively carried forward to the lower end thereof, when by coming on to the projections or vanes E E, it is by them lifted up and discharged into the mouth of the pipe F. Each of them is applied at an angle to a radial line, and the upper surface is inclined towards the head of the cylinder, but it may be curved or provided with sides to facilitate the taking up of the charcoal and its discharge into the pipe, and thence by another pipe to the upper end of the lower retort. The feed pipes may be sufficiently long to discharge the charcoal into the interior of the cylinders. The charcoal received into the lower cylinder is, in the revolution of that cylinder, aided by its inclined direction, carried forward to the lower end thereof, and then such charcoal is lifted by vanes or projections, similar to those above described, and discharged through a pipe G. These pipes are fitted with expansion joints. They may, if desired, be covered with a non-conducting material to retain heat, or they may be cast double for the same purpose. They are kept in contact with the mouths of the cylinders by connections on the flanges. The cylinders are supported on grooved friction rollers, on which they revolve. The re-burned charcoal from the lower retort is received in a chamber cooler, as shown. To the exterior of the chamber is applied water, in fine streams or jets, to hasten the cooling and permit their being made of thicker and more durable materials than usual. Hand and peep-holes are provided at various points, from which the operation may be examined and repairs

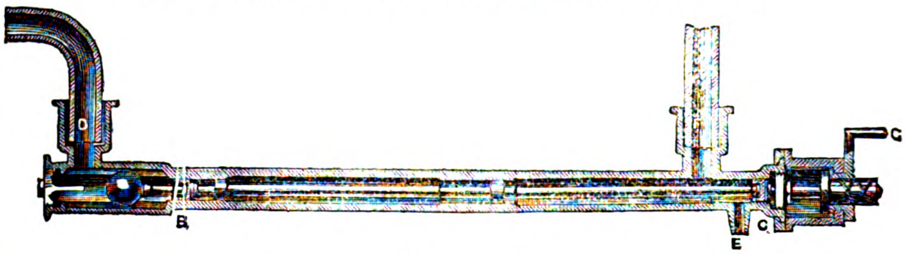
executed. P is a shaft driven by a steam engine or other power, and upon which is formed or affixed a screw, the thread of which takes into the teeth on the ends of the cylinders as the means preferred for giving rotary motion to them. This shaft P may continue along the front and work any number of sets of retorts or cylinders. These cylinders, as will be seen, are enclosed in brickwork, and have suitable flue spaces left for the conveyance of the heated gases from the fire below.

The operation of the apparatus is as follows:—The hopper is kept supplied with charcoal partially dried and heated on the top surface. By means of a valve the supply is regulated to the cylinder. The cylinder, by being inclined and kept in slow rotation, causes the charcoal to traverse its interior and heated surface till it reaches the projections or vanes E E; when entering between these vanes it is carried round till above the mouth of the pipe, when the angle the vanes assume causes it to drop into the mouth of the pipe, whence it is conducted, as stated, to the lower cylinder. The charcoal then, in like manner, traverses the second cylinder, and is discharged therefrom by its pipe into suitable coolers or thin vessels adapted to expose a large surface for cooling, and which are provided with valves or slides, by which the contents can be discharged thence at pleasure. The advantages of this combination and method of working are, that the charcoal gradually passed in a thin body over the heated interior of the retorts is more equally heated, and the gases which are eliminated by the operation are permitted a readier escape, whilst the operation generally is performed in a superior manner. By the continuous discharge into coolers before contact with the atmosphere the destruction of the carbonaceous matter is prevented. By the use of two or more cylinders, in connection with each other, and so arranged that the last, or that in which the operation is finished, receives the greatest heat of the fire, and the first, or that which receives the charcoal first in the series, the least heat, a considerable saving of fuel is effected.

PATERSON'S IMPROVEMENTS IN RE-BURNING ANIMAL CHARCOAL.



JONES' PATENT ANTI-FROST WATER PIPE PROTECTOR.



JONES' PATENT ANTI-FROST WATER PIPE PROTECTOR.

THE above engraving illustrates a very simple apparatus, which will be of the greatest possible utility, comfort, and economy to all householders and consumers of water, where supplied from street mains and other modes of supply; as it will effectually prevent that most annoying occurrence caused by stoppage from frost, and finding no water at the tap when required. The apparatus will ensure a supply in any weather when turned on, and save the expense of constant repairs after severe frosts.

The patentees claim the following advantages which are to be derived from the use of the apparatus:—It prevents the stoppage of water by frost in supply pipes, and enables the water to be drawn when required with a certainty of supply. It prevents house mains and other supply pipes bursting by frost, and other consequent injuries and annoyances. The action is simple and certain, requiring no more trouble than in drawing water from an ordinary tap. It is applicable to any situation, and of service to Railway Companies in the saving of water, and insuring a supply to the locomotive tenders, without the application of a fire-grate to the hydrants, now in use throughout the winter months at all the stations in the kingdom. It is of service to Water Companies, in preventing waste of water from bursting of supply pipes to houses, and from allowing people to let the taps run, as the only existing means of keeping a supply of water in winter, and also from the use of plugs to draw water in the streets for the supply of the inhabitants of the frozen district; and likewise a saving of waste from leakage of taps, as these can be repaired without the necessity of giving notice to the company to turn the water off. It can, when the supply of water is constant and at a high pressure, be made self-acting. It is economical as a first cost in building, and, compared with the annual expense of repairs, and the vexations and hindrances to domestic comfort, and injury to property, it is a desideratum that no house should be without.

The apparatus is so arranged, that a supply of water can be obtained at any time by forcing the rod A towards the back end of the tube. This tube contains two valves, B and C, fixed on the rod A. The motion is effected by simply moving the lever G from left to right; this forces the valve B back into the larger chamber at end of tube, which then admits the water from the inlet-pipe D into the tube. The valve C closes the waste-pipe E, by taking a position (at the time the valve B is forced back) between the waste-pipe E and the rising main F.

The water being then admitted into the tube, passes freely through the rising main F; and this position is maintained while the supply is secured, and no danger of the water freezing need be apprehended when it is being forced with great velocity through the pipes. When the supply is sufficient, the rod A has to be drawn back into its first position, which is simply done by moving the lever G from right to left, and the valve B enters the small part of tube, and shuts off the supply from the pipe D; and the valve C passing to the opposite side of the waste-pipe E, allows all the water in the tube and rising main to pass through the waste-pipe E; thus no water is allowed to stand in those pipes which are exposed to the action of the frost, consequently they can never be frozen up, and all danger of the pipes bursting is avoided, and a constant supply is at all times available when the apparatus is used. We understand the sole licence to manufacture the above apparatus has been obtained by Messrs. Bury and Pollard, Park Iron Works, Southwark.

CREASE'S INVENTION FOR DRILLING, BORING, OR EXCAVATING ROCK.

MR. E. S. CREASE, Mining Engineer of Gracechurch-street, has patented an invention for improved machinery for drilling, and boring rock and other hard substances, which perform as follows:—In perforating rock or other hard substance, instead of striking the boring tool or drill with a hammer. The inventor proposes to effect the same by means of a cylinder and piston, with a suitable hammer head attached to the piston rod to strike the head of the boring tool or other

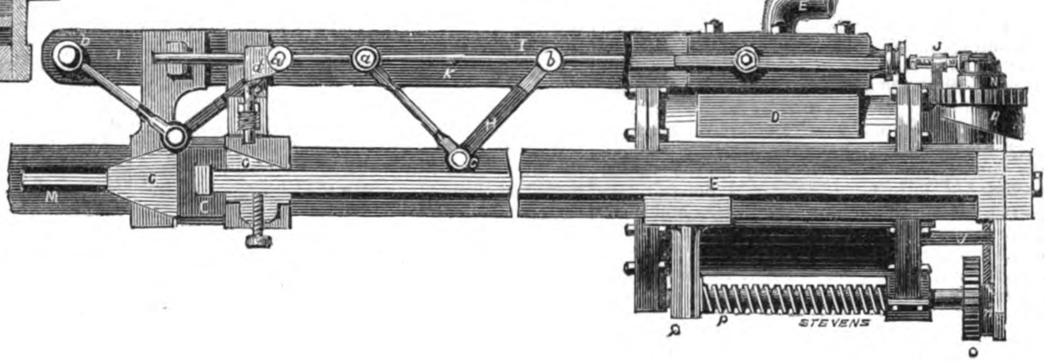

FIG. 4

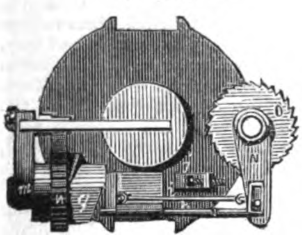

instrument, which is held in suitable guides, the boring tool to be either connected with the hammer head, or affixed to it. Motion is given to the piston by steam or any other motive power through an arrangement of self-acting valves. He also gives a jumping rotative motion to the drill or other instrument by means of the hammer head if attached to it, or if not connected to it by means of tappets on the hammer head communicating the necessary motion through levers to a ratchet wheel on the head of the tool. He also applies a self-acting arrangement, by which the cylinder, piston, and hammer head are steadily advanced as the tool progresses in its work by the following means:—The slide valve rod which works the slide valve for admitting steam to the cylinder, he carries through the slide valve chest, and to the upper end of the rod he attaches a lever, which acts at every alternate motion of the valve rod upon a ratchet wheel mounted upon the top of the cylinder, which ratchet wheel has on its face a cam or shape, which transmits the motion, through another lever to a ratchet wheel attached to a screw, working in bearings at the top and bottom flange of the cylinder. The screw passes through a nut attached to the guides, in which the cylinder and hammer head are free to travel. The shape or cam on the first ratchet wheel is so constructed that motion is only transmitted to the screw at the completion of every half revolution of the boring tool. Upon the necessary motion being given to the screw, and so causing it to travel a certain distance through the nut, it of course carries the cylinder, piston, and hammer head a corresponding distance in the guides. The rate of progress is easily adjustable by means of a set screw, which is so applied as to increase or decrease at pleasure the travel of the lever, which acts upon the screw, and so of course increasing or decreasing the travel of the screw in a corresponding degree. The rate of progress will, of course, depend upon the substance which is being worked. He mounts the whole upon a frame so constructed that it can be worked either vertically, horizontally, or at any angle which may be required.

The engravings show the invention. Fig. 1 is a front elevation; Fig. 2 a side elevation, with a portion of the framing removed to show the valve gear; Fig. 3 is a section of the cylinder; and Fig. 4 is a plan of the top of the cylinder. A is the cylinder in which is a traversing piston B, to which is attached the hammer head C, which in this case is attached to the boring tool M, all supported by the side frames F, which form guides in which the whole is free to travel. E is the inlet pipe at which the steam is admitted into the slide valve chest D, from whence it passes into the cylinder, and acts alternately upon the piston B, after which it is exhausted.

In Fig 3 is shown two valves L L, one in each cylinder cover; in the event of the piston passing the inlet parts at either end it would open the valve, and thus admit sufficient steam to carry the piston past the ports on the return stroke, immediately upon which it would receive its full complement of steam from the slide valve chest. The steam pipes leading to the valves L L are to be connected with the feed pipe E. The pressure of the steam will of course keep the valves closed when not acted upon by the piston. On the end of the piston rod is fixed the hammer head C, which consists of a wheel with teeth cut in its periphery, slightly inclined from the perpendicular, to which is connected the boring tool M. Immediately above and below the hammer head C are fixed two shapes G G; the bottom one is of a conical form as it revolves with the wheel or hammer head C and the boring tool M. These shapes G G communicate the necessary alternate motion to the slide valve rod K by acting upon the levers H H, in the manner shown in the drawing; one end of the levers being attached to the slide valve rod, as shown at *a a*, the other end *b b* being connected to the side frames I I. Upon the shape G acting upon the levers at *c*, the distance between the points *a* and *b* is of course lengthened alternately, and so communicating the necessary motion to the slide valve rod K. On the rod K is fixed a shape *d*, which every time the rod is lifted forces out a stud *e*, which acting upon the toothed wheel *c*, causes it and the boring tool connected to it to revolve at every stroke the same distance that the teeth on the wheel or hammer head *c* are out of the perpendicular. On the stud *e* is a spiral spring *f*, which causes the stud *e* to return to its normal position upon the depression of the slide valverod K, and thus preventing it coming in contract with the wheel C during the down stroke of the piston rod. The upper end of the slide valve rod K, which passes right through the slide valve chest, as shown in section in Fig. 3, acts upon a ratchet wheel N (through the medium of the lever *m*), which ratchet wheel has upon its inner face a shape or cam *g*, which acts upon a lever *h*, to which is attached an india-rubber or spiral spring *i*, which at every complete revolution of the wheel N causes the lever *h* to return, and so by acting upon the ratchet wheel O (through the medium of the lever *n*) on the end of the screw P, passing through the nut Q, causes the cylinder, boring tool, &c., to advance in the guides F a distance corresponding to the distance traversed through the nut by the screw. The small set screws *j* are for the purpose of adjusting the rate of progress, by allowing the levers *m* and *n* to act upon one or more teeth of the ratchet wheels N and O, according to the description of the material being worked.

BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

THE thirty-second annual meeting of this association commenced yesterday at Cambridge. Great preparations have been made by the University and municipal authorities to give *eclat* to the meeting and contribute to the comfort of members. The Senate-house and the halls of

various colleges have been liberally thrown open for the meetings of the sections. The corporation of the borough have placed the Guildhall at the disposal of the association for their general and evening meetings. The members of the British Association retain a grateful recollection of the success which attended their meeting in Cambridge in 1845; while the members of the University and the inhabitants of the town appear to be animated by a common desire to receive their distinguished scientific visitors with due hospitality and respect. The Fitzwilliam Museum, the Geological and Mineralogical Museums, the Observatory, the Museum of Comparative Anatomy, and the Botanic Garden are all thrown open daily during the meeting of the association.

The first general meeting was held at 8 o'clock p.m., in the Guildhall, which was crowded by ladies and gentlemen, among whom were—the the Earl of Enniskillen, Lord Wrottesley, the Vice-Chancellor of the University, Sir P. Egerton, Mr. Walpole, M.P., the Dean of Ely, Mr. Fairbairn, F.R.S., Mr. Tite, M.P., Mr. V. Harcourt, Mr. E. Chadwick, Rev. Dr. Whewell, Dr. Leapingwell, Professors Owen, Huxley, Phillips, Sedgwick, &c.

Mr. Fairbairn, F.R.S., the retiring president of the association, who was loudly cheered on presenting himself, said--"Ladies and gentlemen, it is my pleasing duty to introduce to you Professor Willis, the next chairman of the British Association. I need not refer to the services which Professor Willis has rendered to science; they are well known in Cambridge, and in the country, and appreciated by all the learned societies of Europe. (Cheers.) I congratulate you on his appointment to the chair, and I am quite sure it will do honour to the British Association. (Cheers.) Last year, at the meeting in Manchester, there were brought forward many subjects of great interest to science, which were most ably discussed, and I have no doubt the result of the meeting now taking place under the auspices of the learned Professors of Cambridge will be equally successful. It therefore gives me great pleasure to introduce to you my learned friend Professor Willis, and to resign the chair to that gentleman, who will now address you for the first time as President of the British Association. (Loud cheers.)

Professor Willis then took the chair, and delivered his inaugural address. After glancing at the early history of the association, he said:—"In considering the investigations carried out by committees or individual members, by the help of the funds of the association, it must always be remembered that their labours, their time and thoughts, are all given gratuitously. One of the most valuable gifts to science that has proceeded from our association is the series of its printed reports, now extending to 30 volumes; yet these must not be supposed to contain the complete record even of the labours undertaken at the request and expense of the body. Many of these have been printed in the volumes of other societies, or in a separate form. Several, unhappily, remain in manuscript, excluded from the public by the great expense of publication. I am the more induced to direct attention to this great work at present, because I hold in my hand the first printed sheets of a general index to the series from 1831 to 1860, by which the titles and authors of the innumerable memoirs upon every possible scientific subject, which are so profusely but promiscuously scattered through its 18,000 pages, are reduced to order, and reference to them rendered easy. This assistance is the more necessary because so many investigations have been continued with intermissions through so many years, and the labour of tracing any given one of them from its origin to its termination through a series of volumes is extremely perplexing. For this invaluable key to the recorded labours of the association we are indebted to Professor Phillips, and the prospect of its speedy publication may be hailed as a great subject of congratulation to every member of our body. In every annual volume there is a table of the sums which have been paid from the beginning, on account of grants for scientific purposes. The amount of these sums has now reached £20,000, and an analysis of the objects to which this expenditure is directed will show that if we divide this into eighteen parts it will appear, speaking roughly, that the section of mathematics and physics has received twelve of these parts—namely, two-thirds of the whole sum; the sections of geology and mechanical science two parts each, while one part has been given to the section of botany and zoology, and one divided among the sections of chymistry, geography, and statistics. The greater share assigned to the first section is sufficiently accounted for by the nature of the subjects included in it, which require innumerable and expensive instruments of research, observations, and expeditions to all parts of the globe. If we examine the principal subjects of expenditure, we find in the first place, that more than £1,800 was expended upon the three catalogues of stars—namely, the noble catalogue which bears the name of the British Association, commenced in 1857 and completed in eight years; and the star catalogue from the observations of Lelande and Lecaile, commenced in 1835 and 1838, and reduced at the expense of the British Association, but printed at the expense of Her Majesty's Government. £150 was applied principally to the determination of the constant of lunar nutation, under the direction of Dr. Robinson, in 1837, and to several other minor astronomical objects. At the very first meeting at York the perfection of tide tables, hourly meteorological observation, the temperature of the atmosphere at increasing heights, of springs at different depths, and observations on the intensity of terrestrial magnetism, were suggested as objects to which the nascent organization of the association might be directed. Its steady perseverance, increasing power and influence, as successive years rolled on, is marked by the gradual carrying out of these observations so as to embrace nearly the whole surface of the globe. Thus, under the direction of Dr. Whewell, a laborious system of observations, obtained by the influence and reduced at the expense of the association, who have aided this work with a sum of about £1,300, has determined the course of the tide wave in regard to the coasts of Europe, of the Atlantic, of the United States, of New Zealand, and of the east coast of Australia. Much additional information has been since collected by the Admiralty through various surveying expeditions, but it appears that much is still wanting to complete our knowledge of this subject, which can only be obtained by a vessel specially employed for the purpose. More than £2,000 has been allotted to meteorology and magnetism, for the construction of instruments, and the carrying out of a series of observations and surveys in connection with them. To this must be added a sum, between £5,000 and £6,000, for the maintenance of Kew Observatory, of which more anon. The advance made in these important sciences through the labours of committees of the British Association may be counted among the principal benefits it has conferred. To the British Association is due, and to the suggestion of General Sabine, the first survey ever made for the express purpose of determining the positions and values of the three isomagnetic lines corresponding to a particular epoch over the whole face of a country or state. This was the magnetic survey of the British Islands, executed in from 1834 to 1838, by a committee of its members, General Sabine, Professor Phillips, Sir J. Ross, Mr. Fox, and Mr. Lloyd, acting upon a suggestion brought before the Cambridge meeting in 1833. It was published partly in our volume for 1838, and partly in the *Philosophical Transactions* for 1849. This was followed by a recommendation from the association to Her Majesty's Government, for the equipment of a naval expedition to make a magnetic survey in the southern portions of the Atlantic and Pacific Oceans. This recommendation, concurred in by the Royal Society, gave rise to the voyage of Sir James Clark Ross in the years 1839 to 1843. In a similar manner was suggested and promoted the magnetic survey of the British possessions in North America, authorized by the Treasury in 1841; the completion of the magnetic survey of Sir James Ross, by Lieut. Moore and Lieut. Clerk in 1845, in a vessel hired by the Admiralty; the magnetic survey of the Indian seas by Capt. Elliot in 1849, at the expense of the Directors of the East India Company; and the magnetic survey of British India, commenced by Capt. Elliot in 1852, and completed between 1855 and 1858 by Messrs. Schlagintweit. Finally, in 1857, the British Association requested the same gentlemen who had made the survey of the British Islands in 1837 to repeat it, with a view to the investigation of the secular changes of the magnetic lines. This has been accomplished, and its results are printed in the new volume for 1861. The association also, aided by the Royal Society, effected the organization, in 1840, of the system of simultaneous magnetical and meteorological observations, established as well by our own Government as by the principal foreign Governments at different points of the earth's surface, which have proved so eminently successful, and have produced results fully equalling in importance and value, as real accessions to our knowledge, any anticipations that could have been formed at the commencement of the inquiry. General Sabine, whose labours have so largely contributed to these investigations, has given to the University an admirable exposition of the results during the present year, in the capacity of Sir Robert Rede's lecturer. In 1854, in consequence of representations originating with the British Association, our Government created a special department in connexion with the Board of Trade, under Admiral Fitzroy, for obtaining hydrographical and meteorological observations at sea, after the manner of those which had been for some years before collected by the American Government at the instance and under the direction of Lieutenant Marcy. Observations on the wind have been carried on by means of the various self-registering anemometers of Dr. Whewell, Mr. Osler, Dr. Robinson, and Mr. Beckley, which instruments have been improved, tested, and thoroughly brought into practice by the fostering care of our body; and by the aid of its funds experiments have been made on the subterranean temperature of deep mines, and on the temperature and other properties of the atmosphere at great heights by means of balloon ascents. Four of these were made in 1852, in which heights between 19,000 ft. and 20,600 ft. were reached. But in the present year Mr. Glashier has attained an altitude of nearly 30,000 ft. We may hope that some account of this daring achievement, and its results to science, may be laid before the association at its present meeting. Earthquake shocks were registered in Scotland by a committee of the association from 1841 to 1844, and Mr. Mallet commenced in 1847 a most valuable series of reports on the facts and theory of earthquake phenomena from the earliest records to our own time, which have graced our volumes, even to the one last published. One of the most remarkable and fruitful events in our history in relation to physical observations, is the grant by Her Majesty in 1842 of the observatory erected at Kew by King George III., which had been long standing useless. It gave to the society a fixed position, a depository for instruments, papers, and other property, when not employed in scientific inquiry, and a place where members of the association might prosecute various researches. This establishment has been during the twenty years of its existence, gradually moulded into its present condition of a most valuable and unique establishment for the advancement of the physical sciences. After the first few years its existence was seriously perilled. In 1845 the expediency of discontinuing this observatory began to be entertained, but upon examination it appeared that the services to science already rendered by this establishment, and the facilities it afforded to members of the association for their inquiries, were so great as to make it desirable to maintain it, Again, in 1418, the burden of continuing this observatory in a creditable state of efficiency pressed so heavily upon the funds of the association, then in a declining state, that the Council actually recom-

mended its discontinuance from the earliest practicable period. This resolution was happily arrested. In 1850 the Kew Committee reported that the observatory had given to science self-recording instruments for electrical, magnetical, and meteorological phenomena already of great value, certainly capable of great further improvement, and that if maintained merely as an experimental observatory, devoted to open out new physical inquiries and to make trial of new modes of research, but only in a few selected cases to preserve continuous records of passing phenomena, a moderate annual grant from the funds of the association would be sufficient for this most valuable establishment for the advancement of the physical sciences. In this year it fortunately happened that Lord J. Russell granted to the Royal Society the annual sum of £1,000 for promoting scientific objects, out of which the society allotted £100 for new instruments to be tried at Kew—the first of a series of liberal grants which have very greatly contributed to the increasing efficiency of the establishment; but we have insured its continuance. It now contains a workshop fitted with a lathe, tools, planing-machine. &c., by which apparatus can be constructed and repaired, and a dividing engine for gaaduating standard thermometers, all presented by the Royal Society. The work done, besides the maintenance of a complete set of self-recording magnetographs, established in 1857, at the expense of £250, by the Royal Society. consists in the construction and verification of new apparatus, and in the verification of magnetic, meteorological, and other instruments sent for that purpose by makers. For example, all the barometers, thermometers, and hydrometers required by the Board of Trade are admirably tested, and standard thermometers are graduated, magnetic instruments are constructed, and their constants determined for foreign or colonial observatories. Sextants also are verified. An example of its peculiar functions is given in the very last report for 1861, when it appears that an instrument contrived by Professor William Thomson, of Glasgow, for the photographic registration of the electric state of the atmosphere, has been constructed by Mr. Beckley, in the workshop of this observatory, with mechanical arrangements devised by himself, and that it has been in constant and successful operation for some time. Those who have experienced the difficulty of procuring the actual construction of apparatus of this kind devised by themselves, and the still greater difficulty of carrying out the improvements and alterations required to perfect it when brought into use, will agree that the scientific importance and utility of an establishment cannot be overrated in which under one roof are assembled highly skilled persons, not only capable of making and setting to work all kinds of instruments for philosophical research, but also of gradually altering and improving them as experience may dictate. The creation of this peculiar observatory must be regarded as one of the triumphs of the British Association. As far as the association is concerned, its maintenance has absorbed between £5,000 and £6,000, and the annual sum allotted to it from our funds has for each of the last six years reached the amount of £500. The construction of the photoheliograph may be quoted as an example of the facilities given by this establishment for the developing and perfecting of new instruments of observation. A suggestion of Sir John Herschell in 1854 that daily photographs of the sun should be made, has given birth to this remarkable instrument, which at first bore the name of the solar photographic telescope, but is now known as the Kew photoheliograph. It was first constructed under the directions of Mr. De la Rue, by Mr. Ross, &c. The British Association aided in carrying out this work, by assigning the dome of the Kew Observatory to the instrument, and by its completion in 1857, in their workshop, by Mr. Beckley, the assistant; but the expense of its construction, amounting to £180, was supplied by Mr. Oliviera. On occasion of the eclipse in 1860, this instrument was conveyed to Spain, under the care of Mr. De la Rue, who most successfully accomplished the proposed object by its means, and was replaced at Kew on his return. But to carry on the daily operation for which it was constructed, requires the maintenance of an assistant, for which the funds of the association are inadequate, although it has already supplied more than £200 for that purpose. Mr. De la Rue, in consequence of the presence of the heliograph at Kew being found to interfere with the ordinary work of the establishment, has kindly and generously consented to take charge, for the present, of the instrument at this observatory, and at his own observatory when celestial photography is carried on. But it is obvious that the continuation of these observations for a series of years, which is necessary for obtaining the desired results, cannot be hoped for unless funds are provided. I cannot conclude this sketch of the objects of the physical section to which the funds of the association have been principally devoted, without alluding to Mr. Scott Russell's valuable experimental investigations on the motion and nature of waves, aided by £274. If we now turn to geology, we find £2,600 expended; of which £1,500 was employed in the completion of the fossil ichthyology of Agassiz, and Owen's reports on fossil mammalia and reptiles, with some other researches in fossils. The remainder was principally devoted to the survey and measurement, in 1838, of a level line for the purpose of determining the permanence of the relative level of the sea and land, and the mean level of the ocean, and to the procuring drawings of the geological sections exposed in railway operations before they are covered up—a work which was carried on from 1840 to 1844, when the drawings were deposited in the Museum of Practical Geology, and the further continuance of it handed over to the geological surveyors of that establishment. £2,300 has been devoted to the carrying out of various important experimental investigations in relation to the section of mechanical science. Of this sum £900 was paid between 1840 and 1844 in aid of the most important and valuable series of experiments on the forms of vessels, principally conducted by Mr. Scott Russell, in connexion with the experiments on waves. This investigation was ready for the press in 1844, but it is greatly to be regretted that the great expense of printing and engraving it has hitherto prevented its publication. Nearly the same sum has given to us various interesting and instructive experiments and facts relating to steam engines and steam vessels, carried on by different committees from 1838 to the present time, among which may be especially noted the application of the dynamometric instruments of M.M. Morin, Poucelet, and Moseley, to ascertain the duty of the steam engines from 1841 to 1844. Experiments on the strength of materials, the relative strength of hot and cold blast iron, the effect of temperature on their tensil strength, on the effect of concussion and vibration on their internal constitution, carried on principally by our late president, by the late Mr. Eaton Hodgkinson at different intervals from 1838 to 1856, have been aided by grants, amounting to £400. The remainder of the sum above-mentioned was principally devoted to the experimental determination of the value of railway constants by Dr. Lardner and a committee in 1838 and 1841. The section of botany, zoology, and physiology has absorbed about £1,400, of which nearly £900 has been applied to zoology, partly for the expense of dredging committees, for obtaining specimens of marine zoology on our own coasts, and in the Mediterranean and other localities, and whose useful labours have been regularly reported from 1840 to 1861, but principally for zoological researches in different districts and countries. In botany may be remarked the labours of a committee, consisting of Professors Daubeny, Henslow, and others, formed in 1840 to make experiments on the preservation of vegetative powers in seeds, who continued their work for sixteen successive years, reporting annually, and assisted by a sum of £200. The greatest age at which the seeds experimented upon were found to vegetate was about 40 years. Another committee, with Mr. Hunt, was engaged during seven years, from 1841, in investigating the influence of coloured light on the germination of seeds and growth of plants. These are specimens of the admirable effect of the organization of an association in stimulating and assisting with funds the labours of investigators in new branches of experimental inquiry. It would occupy too much time to particularize a variety of interesting investigations in the remaining sections to which small sums have been assigned." The President then referred to the report of the Manchester meeting, and instanced some of the most striking advances since made in the various sciences. He the said:—"Before I conclude I have the painful duty of reminding you that since our last meeting we have had to deplore the loss of that most illustrious patron of science and art, his Royal Highness the Prince Consort, the president of our association at Aberdeen, and the chancellor of this university. In the latter capacity he afforded us many opportunities of observing his scientific attainments and genuine zeal and love for all branches of knowledge. His gracious kindness and respect for men of science and literature have left an impression upon us that can never be effaced. I must also ask a tribute to the memory of our late professors of chymistry and botany, both of whom did in their lifetime excellent good service to science, and more especially to the British Association—Professor Cumming contributing one of the invaluable primary reports upon which our proceedings were based, as well as other communications—Professor Henslow by various reports, some of which I have already alluded to." The Professor was loudly cheered during the delivery of his address. At its close—

Professor Owen, who was loudly cheered, moved a vote of thanks to the learned president for his comprehensive, varied, and excellent address.

The Dean of Ely seconded the motion. The clergy of the Church of England most cordially recognized the excellence of the work of the British Association, and with all heartiness and solemnity wished them God-speed in their great work. (Cheers.)

The resolution was carried with acclamation.

Professor Willis acknowledged the compliment; after which the meeting broke up.

NEW JETTY AT DEVONPORT DOCKYARD.

An important and rather extensive work has just been completed at the Royal Dockyard, Devonport. It consists of an addition to what has been heretofore known at that establishment as the "Anchor Wharf," the name of which sufficiently well indicates the purpose to which it was devoted. The enormous increase in the strength of the British steam navy during the last few years has rendered it a matter of absolute necessity to increase, commensurately therewith, facilities for supplying it with coal. It is to this end that the new jetty at Devonport has been constructed. The structure does not extend itself into the harbour at right angles from the face of the anchor wharf, as its name might seem to imply, but runs parallel with that erection. The jetty is 350 ft. long and 40 ft. wide. A row of cast iron piles, each of which is 36 ft. in length, and weighs 3½ tons, forms the outer line of the jetty, and gives great stability to it. As the bed of the harbour is composed of tolerably hard limestone rock, the pitching and driving of the piles has been attended with considerable mechanical difficulty and much labour. Now that they are all in their places, however, they may be deemed immovable, and almost imperishable, and this fact compensates, to some extent, for the exertions used in implanting them.

The heads of the iron piles stand about 10 feet above low water mark, and are fitted with sockets for the reception of timber uprights for the support of the superstructure. These sockets are each 2 ft. 6 in. in depth, and 2 ft. 4 in. by

1 ft. 2 in. in width, whilst the double timber uprights resting in them are each 15 ft. in length, and iron-capped, for the reception of cross girders, which are also of cast-iron. The length of the girders is 21 ft. each, and the weight 2 tons. Their inner ends rest upon an intermediate row of piles, similar to those described, whilst another series of girders connects the whole to the face of the old wharf. On the tops of the girders are placed joists, 14 in. by 7 in., and spiked down to these is a flooring of oak, $4\frac{1}{2}$ in. in thickness, and laid diagonally, for the purpose of imparting additional strength to the erection. The jetty is formed in bays, or spaces, each 13 ft. from centre to centre. Diagonal framings of whole timbers again connect the piles to the wharf wall, whilst longitudinal timbers unite the piles and braces to each other. In the front of each bay there are also wrought-iron tye rods, which cross each other, and add yet further strength to the work. Rubbing pieces, composed of whole timbers, are bolted to the front of the outer line of piles, so as to prevent mischief arising from the impact of heavy vessels lying alongside, and disturbed by the swell. At the average height of spring tides there is forty feet of water at the new coaling jetty, so that the largest steam ships at present employed by the British government may approach it without the slightest danger of grounding. Seen from the water the new jetty, although, as we have shown, of massive proportions, has a peculiarly graceful and light appearance, and it adds indeed a new and pleasing feature to the outline of the dockyard. It will, therefore, prove not only useful but ornamental.

The work was designed, and has been constructed by Henry Grissell, Esq., of the Regent's Canal Iron Works, Eagle Wharf-road, London, a gentleman whose successful efforts in the way of iron bridge building, and the erection of dock roofs, lighthouses, piers, &c., &c., have obtained for him a high reputation. Nine months have sufficed for the completion of the jetty, and to Mr. Gideon Scott, manager at Devonport for Mr. Grissell, belongs the credit of having personally and practically directed the whole of the proceedings in connexion with it. No accident occurred during the progress of the work, which is destined, we imagine, to remain for centuries as a testimony to the marine engineering skill of Mr. Grissell and his assistants.

Correspondence.

THE WAVE-LINE THEORY.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

SIR,—It is easy to refute Mr. Moy, but hard to convince him. But the "inexorable logic of facts" has been operating upon the Wave-line theory since Mr. Moy read his paper in 1857. And that theory is now regarded by most practical naval architects as an hallucination. A bow having its water-line a concave curve from the stem to an indefinite distance aft, and there joined to a convex curve, which unites it—at an indefinite distance further aft, to the side of the ship, is now generally understood to be a wave-line bow. Mr. Moy demurs to such a bow being so designated. Very well! The term may be a misnomer. But there are persons who designate some water-lines *plumb-bolt lines*, and Mr. Moy's water-lines *winch-handle lines*. "What's in a name?" The important fact, patent to everybody connected with ship building, is, that the pretentious advocates of the wave-line—whatever it may be—have utterly failed to establish its practical pre-eminence.

Mr. Moy can see, according to his own exposition of his theory, a close analogy existing between a force exerted upon one extremity of a crank, the other extremity of which is held by an axis upon which it revolves, and the pressure of a ship's bow cleaving her way through water, every particle of which moves freely in any direction which the complicated forces acting upon it may necessitate—I cannot. His laws of induction and mine differ. So we had better not discuss theory. With regard to facts, an extended experience enables me to say, they are against him. Has he ever made any inquiries respecting the little yacht "Titania," and the large steamer "Adelaide," both constructed upon the orthodox wave-line principle? The reports which have been made to me of both are very unfavourable. Has he ever ascertained, with regard to the two vessels he mentions, their length, displacement, indicated horse-power, and speed, and compared them with similar data of many steamers not having wave-line bows? He should do so. The result might shake his convictions.

Mr. Moy boldly and explicitly expresses his opinions, and attests them with his name. For this he is deserving of respect, and I should be sorry to write anything that would jar upon his feelings. But sincerity and enthusiasm, however admirable, may produce fanaticism in science as well as in religion, and I crave Mr. Moy's pardon for having arrived at the conclusion that his intense regard for the wave-line arises more from the suggestions of his imagination, and his aversion to giving up an untenable position, than to any process of philosophical experiment or ratiocination.

I have now the lines of the *Yankee* yacht "America" before me. And I can assure Mr. Moy that she has scarcely more concavity in her load line than would be sufficient to break in the straight line of the stem to the convex line of her bow without an angle at the "hood ends." If the drawing of the fore-body were submitted to him, he would at once repudiate it as a wave-line bow. But supposing otherwise. Has not the superior sailing of the "America" been traced to her sails and management? Would any yachtsman now build a yacht upon her model? It may, moreover, be fairly urged that whatever the excellence of horizontal "wave lines" may be, as fore-and-aft-rigged vessels are always considerably deflected while under weigh, the *actual* water line forms a widely-diverging diagonal line with such horizontal lines, and, consequently, differs very widely from them in character.

Since your last publication I have made every enquiry in my power respecting the Duke of Sutherland's yacht, now lying in the Victoria dock. Mr. Moy will admit that she is a veritable wave-line bowed yacht. I have conversed with parties knowing all about her from the time of her keel being laid on the blocks till her return from Russia. I find that my impression of her is abundantly confirmed by her behaviour. She is, as far as speed is concerned, a failure. Esthetics do not pertain to our argument or I might be tempted to dilate also upon her ugliness.

I am averse to controversy, and shall therefore allow Mr. Moy to have the last word, unless he challenges the veracity of any of my statements. Before concluding, I must confess myself sorely mortified by Mr. Moy throwing down the gauntlet upon such a *trifling* affair as the construction of a vessel to steam twenty miles an hour. Why, I have been anxiously waiting three years for his vessel, then *in passe*, which he assured us would go fifty miles an hour. Twenty miles an hour, forsooth, who would not deem it *in fra dig* to waste time, ink, and drawing paper upon such a sluggish creeping thing, with the prospect of a *fifty miler* before him? No! no! I shall try my hand at nothing less than an amendation of that prodigy *when it appears*.

NAUTICUS.

P.S.—The "Psyche's" bows can no doubt be very much improved without adopting the wave line.

HOW TO PURIFY AIR IN WELLS.

SIR,—Within the last few days no less than five lives have been lost in wells. In one they threw down fire and water for a counteraction; water may have been of service, but as for the fire, I consider it useless.

If chance threw me in the way of such a calamity, I should make use of a well rope, clothes line, bed cords, or anything suiting the occasion, to attach to an umbrella, a parasol, copper lid, tea-tray, carpet, a sack with hay or straw in it, blanket sheet, or coat; and with any of those articles, or more if means allowed, I should drop it down the well, draw it partly up, down again, now up all the way; do as before over and over again until the air was so disturbed and changed that one might venture down in safety, and the one or those below would be relieved before got at.

I am of opinion that the following advice should be widely circulated:—Disturb the air in the well with the first thing at hand, and lose no time in doing it, for quickness will prolong vitality in the well.

If some of your readers who can have access to a well were to get some squibs, and by means of a cord let two or three off near the bottom, and note the time the smoke lingered there, then let off other squibs again, supposing a friend below in jeopardy. Now set to work in real earnest with something to the purpose, and each stroke will tend to dilute and change the air contained there.

Suppose a tank of water five feet deep, and a tube four feet long and 2 in. diameter, closed at bottom, and standing in the tank; there shall be at the bottom of the tube 3 in. of porter or muriatic acid, the rest is water, of course, and this said tube we will call a well, the water to represent air, and the other foul air—

Question—Is it possible, with a metal button attached to a thread, to rid such a tube of the foul portion?

I say yes.

Yours respectfully,
GEORGE BOURN.

67, Murray-street, Hoxton,
Sept. 29, 1862.

PROTECTING SHIPS' SCREWS.

SIR,—Your correspondent, Mr. Cunningham, has handled this important subject so ably and fully, in enumerating the many disasters arising from the fouling of screw propellers, that to pass by unheeded his timely warning would approximate to insanity.

Mr. Cunningham is in error, however, in stating that the fouling of the screw has been uncared for; as far back as 1853 the subject engaged my attention, and, after considerable study, I discovered that screw-protectors could be *dispensed* with, simply by altering the shape of the blades, and constructing them *round*—the tendency of this formation being to *throw off* everything coming in contact; and had the Confederate steam-ram, "Arkansas" (referred to by Mr. Cunningham) been fitted with a screw so constructed, she could have defied everything in the shape of ropes, chains, or spars; therefore, to advocate the adoption of screw-protectors, however simple, is not only a waste of time but of money also, especially as the remedy is so easily and effectually secured by altering, as we before observed, the shape of the blades. (See MECHANICS' MAGAZINE, June 10, 1859.)

Permit me to embrace this opportunity of thanking Mr. Cunningham for the illustrations of his patented protector, which my previous letter called forth. I admit its simplicity; at the same time, it possesses two serious and insurmountable drawbacks, viz.—it would be an infallible receptacle for sea-weed, &c., also an obstruction to the ship's progress.

I am, Sir, faithfully yours,
WILLIAM HEWITT.

Bristol, September 26, 1862.

SIR,—In your Magazine of the 19th inst., you give a drawing of a patent improved watch regulator, by N. Wighton. I beg to inform you that that invention is nothing new, having been proposed by me to Messrs. J. and H. Marshall, of Edinburgh, several years back, but they told me that it had been tried and did not answer, and showed me a motion which is cleverly expressed by the words in your notice from "a quadrant" to "turned," but very coarsely manufactured. I mentioned the same proposal to a scientific watchmaker and great mechanic a short time ago, but was told it was no practical use.

Your obedient servant,
COPPER CAP.

September 29, 1862.

THE IRON-PLATED RAM "DEFENCE."

SIR,—Considerable interest has been excited respecting this ship by a paragraph which appeared in the *Times* some few weeks ago stating that she had knocked a large hole in her bottom, had filled two compartments with water, and was only saved from sinking by her water-tight bulkheads. This cock-and-a-bull story turns out to be entirely imaginary, and seems to have been got up to gull the leading journal on the question of *iron ships*. On inquiry we find that the "Defence," after passing the Cattegat, touched the ground during her cruise in the Baltic *three* times. The two first times the points touched were presumed to be either sand or soft mud. The third time, on the passage from Stockholm to Revel, she passed over a rock. The officers describe the sensation of passing over the rock as something horribly unpleasant. One officer stated that he was nearly thrown off the bridge on the deck; several got out of bed and rushed on deck, the vessel going at the time about eight knots an hour. At the same time she was observed to make a regular plunge, rising first at the bow, and then at the stern, some five or six feet. After this

a leak or leaks were fully expected, but nothing appeared to give the slightest foundation for the strange report in the *Times*.

The ship has just been put into dock at Portsmouth, and after a careful inspection some half-dozen rivets were found started, but every plate and joint in the bottom found as sound and good as the day the vessel was launched. It is agreed by all on board that had she been a wooden vessel she would have stuck fast on the rock and injured herself very severely. All the officers (many of whom went away very much prejudiced against the ship) now speak in unqualified praise of her good qualities. They say she is as steady as a church, neither pitching nor rolling. She can both steam and sail (though lightly rigged) with any vessel in the fleet. In fact, they have returned home after a very pleasant cruise, in which the qualities of the vessel have been well tested, and they themselves treated by Swedes, Danes, and Norwegians in a right royal and hospitable manner, fully convinced that there is more in the iron ships than they had ever dreamed of in their philosophy.

J. S.

OVERLOADING OF VESSELS.

SIR,—In your Magazine of the 26th inst., when alluding to the number of vessels wrecked in 1861, you say, "with causes so well defined is not the remedy obvious?" There is one remedy I have long advocated, viz.,—that every vessel should have a light and a load water line so marked as not to be easily effaced. The former should never show on an outer bound vessel, the latter should always be in sight. Some years back a bill was passed to prevent the overloading of stage coaches—why should not there be a bill to prevent the overloading of vessels. Hundreds of lives and millions worth of property would be saved annually by such a measure.

I remain, yours truly,
A. W. SKINNER, Captain, R.N.

Belfast, 27th Sept., 1862.

PRODUCTION OF CORK.

IN the "Mémoires de la Société de Physique" of Geneva, is an interesting paper by M. Casimir de Candolle on the growth of cork. Although this useful substance exists in varying quantity in the bark of all phanerogamous plants, and in several cryptogamous, yet for commercial purposes it is wholly procured from two species of oak, *Quercus occidentalis*, growing in the south-west of France and in Portugal, and from *Quercus Suber* (the cork tree), growing in the south-east of France, in Italy, in Algeria, and in the isles of the Mediterranean. The acorns of the former species take two years to ripen. In 1859 M. C. de Candolle, while staying in Algeria, studied the development of the bark of the latter species. It is composed of four layers—the epidermis, the corky envelope, the cellular envelope, and the liber which covers the soft wood. These four parts increase independently of each other year by year. In the third or fourth year the epidermis, having attained the limits of its elasticity, splits longitudinally, and a marked change takes place in the corky envelope, which gradually takes up the appearance of true cork; new layers are produced, and the transformation of cellulose into cork steadily goes on. The cork thus naturally developed has no commercial value. It is termed "male," and the first act (*demasclage*) of the cultivator is to separate it from the trunk, which thus leaves exposed the liber, termed "mother." The tree is then left to itself, and the cork begins to grow again, while the sap is flowing, in consequence of the exposure of the liber. If a trunk left in this state several months be cut down, in the section a ring of cork will be found formed in the interior of the "mother," at a variable distance from the surface of the trunk. All the exterior portion of the "mother" is dead, and splits as the tree grows, and the interior portion (new cork, termed "female") is developed. This "female" cork grows in the same manner as the "male," that is, by the addition of annual layers on the internal surface; but it is much finer and more elastic, and is the cork of commerce. These various stages of growth are exhibited in a series of beautiful plates. In the course of his researches M. de Candolle was led to observe the importance of the desiccation of the "mother," and to infer that, in proportion as this desiccation could be hastened, so much sooner would fresh layers of cork be produced. This idea he found to be correct. He observed several trees in which fires, after having charred the male or female cork, had determined the formation of a layer of female cork in the interior of the "mother." He states that he has seen a specimen, composed of three layers of "female" cork, separated by little zones from the "mother," the fourth layer, which enveloped the whole, having disappeared in consequence of the fire. The thickness of these zones, increased by the application of boiling water, does not diminish by cooling. Other peculiarities of this remarkable substance are noted in the memoir.—*The Building News*.

SPRAY SUPER-HEATING STEAM ENGINE.

A SHORT time since a patent was taken out in this country to generate steam on an ingenious principle, and we now see, from the *Scientific American*, that a steam engine working on the principle, may be seen in New York. "We will briefly state," says that journal, "wherein the invention differs essentially from the ordinary steam engine. For the latter, as every body knows, a boiler is used containing a considerable quantity of water, to which the heat of the furnace is most directly applied, and from which the steam is generated. Such a boiler is a magazine of force, because it contains a far greater amount of steam and heated water than is required to supply the engine at each stroke. Herein consists the danger from explosions in common boilers. A hot-air engine has no magazine of force like a steam boiler. Its heater is supplied with the exact amount of air requisite for each stroke, hence its immunity from explosion. This new engine embraces a similar principle. It has a peculiarly-constructed heater, into which the exact quantity of water for each stroke is fed, in the form of spray, then it flashes into steam and passes over an extended heated surface to the working cylinder."

The engine exhibited is single-acting, and of the following dimensions:—Its steam cylinder is 7 inches in diameter; the stroke of piston, 7 inches. It is situated upon a small tank 30 by 34 inches, which forms the bedplate and the heater of the feed water. The feed pump has a stroke of one-fourth of an inch, and the water is fed through a ¼-inch pipe, the steam heater, outwardly, resembling a vertical cylindrical stove. It is 13 inches in diameter, and 30 inches in height. There are 19 double tubes inside and the steam passes between these and is heated on two sides. The circular grate containing the fire is capable of being adjusted by a lever and set at any required distance from the bottom of the heater. We have examined this engine working with super-heated steam at 50-pound pressure, and running at the rate of 87 strokes per minute. The steam exhausts into the tank upon which the engine stands; the feed water, nearly at the boiling temperature, is conveyed into the heater in a fine shower through a small conical chamber on the top of the heater. A small quantity of superheated steam is contained in the heater, and the feed water, in the form of spray, is instantly converted by it into saturated steam. The pipe for supplying the cylinder with steam is situated nearly at the bottom of the heater, hence the saturated steam formed from the feed-water at the top of the heater has to pass in a current between the double tubes on its way to the cylinder, and it thus flows over a very extended heating surface and becomes superheated. A constant current of steam is maintained in this manner over the heated surfaces of the tubes. By such a heater, and such arrangements of the parts of the engine, nearly all the heat is economized, and a perfectly safe steam-engine is secured. If the feed pump were to cease working, or the supply of water to become exhausted, the heater would become like an empty oven after a few strokes, and the engine would stop of itself. For pumping water, printing presses, sawing wood, and various operations requiring a small moter from 1 to 10-horse power, this engine appears to be well adapted, as it is compact, safe, and easily controlled.

DISCOVERIES AT POMPEII.

UNDER the government of the Neapolitan Bourbons, it was the custom to unearth a house at Pompeii on the occasion of a visit from some illustrious guest of the king. The visitor was allowed to pay the expenses of the honour conferred upon him. A fear was entertained that if all the buried treasures of the city were at once exposed, all interest in the discoveries would gradually die out, and "strangers' money" would soon be wanting to gladden the eyes of Neapolitans. Moreover, if the work had been at once completed, the king must of necessity have paid the expenses. Thus, by spreading it over a number of years, the appetite for antiquities was fed but never satiated, and the cost of entertainment did not tax the king's pocket. The "Ré Galantuomo" does not, it appears, act on this shabby system, for we hear that no less than three houses have within the last month been exposed to view. One is of unusual extent and magnificence, and is enriched with wall-paintings of rare design and workmanship. It forms another illustration of the 6th book of Vitruvius, wherein the domestic architecture of the Romans is so minutely described, and recalls Pliny's account of the luxury and splendour in which the more favoured citizens indulged; but neither Crassus, Pollio, or Lucullus, would ever have placed "Salve Lucrum," as we find the ashed-out owner of the latest discovered villa has done, upon his door-step. We have heard already of "salve" and of "cave canem," and we have seen them repeated upon English door-mats, but the new inscription will have, we fancy, no duplicates made of it.

The other discovery is a baker's shop, which has, of course, been closed for nearly 2,000 years, but in which everything has remained in such order that the baker might be supposed to have just left it, and might be momentarily expected to return and resume his vocation.—*Building News*.

Gossip.

It has been discovered that when gas pipes constructed of copper or bronse have been long submitted to the action of ordinary coal-gas an explosive compound of copper and acetylen (one of the many ingredients of coal-gas) is formed. When dry, this compound detonates with extraordinary violence as soon as it is rubbed, struck, or heated. Already some accidents have occurred, and some workmen have lost their lives while cleaning large copper gas pipes, from this circumstance. No such explosive compound appears to be formed when iron or lead are used. It is evident that large copper gas-pipes are unsafe, and that some other metal should be substituted for the copper, as the latter may give rise to explosions at any moment. As concerns small pipes constructed of this metal, they should not be allowed to get foul, and when about to be cleaned hydrochloric acid should be introduced into them for about ten minutes before they are submitted to any heat or friction. Hydrochloric acid decomposes the explosive compound, combines with the copper, and puts the gas acetylen in liberty. The acid may then be washed out with hot water.

The Pittsburgh *Chronicle* states that the Fort Pitt works in Pittsburgh, are turning out the immense fifteen-inch guns now at the rate of three a week. These guns weigh each in the rough about 70,000 lbs., and, apart from the difficulty of casting, the labour of handling, turning, and finishing such a mass of metal must be immense. There are four of these guns now in the lathe, and by the time these are out others will be ready to take their place. It is the intention to turn out three a week, we believe, for the balance of the year. These guns are intended for the new "Monitors," and are the most formidable of their character in the world. Arrangements are now in progress for casting a twenty-inch gun. This latter gun will throw a ball of one thousand pounds, and is expected to have a range of four miles.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

The Abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following Table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved, and combined with all the advantages of a division into classes. It should be understood that these abridgements are prepared exclusively for this Magazine from official copies supplied by the Government, and are therefore the property of the Proprietors of this Magazine. Other Papers are hereby warned not to produce them without an acknowledgement:—

Steam Engines, &c., 691.
Boilers and Furnaces, 670, 672, 684, 689.
Roads and Vehicles, including railway plant and carriages, saddlery and harness, &c., 666.
Ships and Boats, including their fittings, 695.
Cultivation of the Soil, including agricultural implements and machines.
Food and Beverages, including apparatus for preparing food for men and animals.
Fibrous Fabrics, including machinery for treating fibres, pulp, paper, &c., 678, 683, 685, 686.
Buildings and Building Materials, 680.
Lighting, Heating, and Ventilating, 664, 673, 692, 698, 705, 722.
Furniture and Apparel, including household utensils, time-keepers, jewellery, musical instruments, &c., 687, 693, 696, 703, 711, 713, 716, 728, 729.
Metals, including apparatus for their manufacture, 704.
Chemistry and Photography, 677, 681.
Electrical Apparatus, 665, 708.
Warfare, 679.
Letter-Press Printing, &c., *none.*
Miscellaneous, 662, 663, 667, 668, 669, 671, 675, 676, 682, 688, 698, 700, 701, 706, 714, 715, 721, 723. 726, 727.

662. G. Davies. *Improvements in attaching artificial teeth to plates and to each other, and in moulds for forming artificial teeth.* (A communication.) Dated March 11, 1862.

The first part of this invention consists in securing artificial teeth to metal plates, by interposing between the said teeth, by plates, a strip or mass of gum or india rubber, and vulcanizing or hardening the same, after the teeth have been adjusted to the plate; also in forming dove-tailed recesses in artificial teeth, for the purpose of securely attaching the teeth to the plate and to each other by vulcanizable gum, or any other suitable cement; also in the use of staples embedded in artificial teeth as a means of securing the latter to vulcanizable gum plates in the manner described. The second part of the invention consists in making moulds for forming artificial teeth, substantially as described, so that depressions of any size or shape may be formed in the bases of the teeth. In attaching teeth to a metal plate by means of vulcanizable gum, a plate of the desired form is first prepared by any of the known processes, and at the point where the teeth have to be secured, a metal rib is soldered or otherwise secured to the plate. This rib may be plain, but it is preferable to make it thicker on the outer edge than it is at the point where it is secured to the plate, or the rib may be perforated or serrated. In the teeth, or block of teeth, as the case may be, is formed a groove or recess, to coincide with the rib or projection of the plate, the groove being somewhat larger than the rib, and dovetailed, as explained hereafter. A strip or sheet of vulcanizable gum is placed over the rib of the plate, care being taken to keep both the teeth and plate warm. The teeth are now applied to the plate and pressed tightly against the same, so that the rib of the plate may penetrate the groove of the teeth, carrying with it a sufficient quantity of gum to make a tight joint, and to fill up all irregularities or interstices. The whole is then placed in a mixture of plaster of Paris and whiting, and the gum subjected to a vulcanizing or hardening process, when the block of teeth will be found to adhere with the required tenacity to the plate, the interstices in the block and between the block and plate being filled with the vulcanized gum, and the joint presenting a smooth and uniform appearance.—*Patent completed.*

663. W. Clark. *Improvements in apparatus for effecting submarine operations.* (A communication.) Dated March 11, 1862.

This invention relates to the construction of a submarine boat, applicable as an engine of warfare, or for other submarine operations. The boat is formed of two concentric cylinders, having a space between them in which to introduce water to any desired amount, for the purpose of increasing the weight of the boat, and so cause it to sink. This water chamber may also be emptied by means of reservoirs placed in the interior of the boat, the water being ejected behind, for the purpose of lightening the boat, and causing it to rise to the surface. The inner and outer cylinders are independent of each other, so that the movements of the exterior cylinder shall not interfere with those of the inner one, which should always retain its normal position. An ether, or engine and boiler are placed in the boat for imparting motion to a screw propeller, and also for emptying the water contained in the chamber between the two cylinders. The boat is also furnished with instruments of destruction or working tools, according to the purpose to which it is to be applied. Its equipment also includes electric apparatus, steering gear, with manholes suitably arranged, and buoys.—*Patent abandoned.*

664. A. R. L. De Normandy. *Improvements in connecting gas and other pipes.* Dated March 12, 1862.

For the purposes of this invention the pipes to be connected are made plain at their ends, that is to say, without sockets, flanges, or projections, and a disc or plate with a hole in the centre of it—the diameter of which should be rather larger than the external diameter of the pipes—is then slipped over the ends of each pipe, and a washer or packing of vulcanized india rubber, smaller than the pipes to be united, is then slid over each end of the said pipes, so as to grip them tightly; or a washer of other suitable material other than vulcanized india rubber, such, for example, as gasket and tallow, or gasket and red lead, or other similar or analogous substance is used; the said gasket should be tightly wound round the end of each of the pipes, leaving, however, a portion of each pipe to protrude beyond the said washers or packing, and afterwards over the ends of the pipes and between the said washers or packing a short length of tube or plain socket, made just to fit loosely to the exterior of the pipes, is passed. The ends of the pipes to be connected are then butted end to end, so as to meet about midway within the short exterior tube, or loose socket, and the plates or discs are drawn towards each other by bolts, the washers being by this means compressed between the plates or discs and the ends of the short tube, and a secure joint is thus made.—*Patent completed.*

665. A. J. Russell. *Improvements in the arrangement of the electric conductors for submarine telegraphs.* (A communication dated March 12, 1862.)

This invention consists in twisting, coiling, or winding the conducting wires for submarine telegraphs around the cable or core, that is, giving them the form and direction of helical or spiral wires, instead of straight longitudinal wires, as heretofore adopted; and the inventor now uses from one to eight or more such twisted or coiled wires or conductors, the insulation of each being insured by a covering of silk; and over this he now prefers to use a covering or insulator of gutta percha or india rubber, and over this again a covering of hemp that has been steeped in tar, grease, and such like substances, and over all the external sheath composed of small cords of hemp, or of hemp and fine steel wire, that has been steeped in grease, tar, and such like substances.—*Patent abandoned.*

666. J. Fawcett. *Certain improvements in the manufacture of cranks, and crank axles for locomotive and other engines.* Dated March 12, 1862.

This invention consists in making such cranks hollow instead of solid as heretofore. The mode of making cranks for locomotive and other engines according to this said invention is by taking a number of bars of fibrous iron and welding the same together in the form of a tube, and afterwards bending them to the required form, for a crank, which crank the inventor prefers to make hollow from end to end. The same may, however, be made solid at each end of the crank shaft, and hollow in the cranked parts. He also proposes to make such cranks by casting in steel or other metal, in which case he prefers to introduce a core so that the cranks may be hollow when cast.—*Patent abandoned.*

667. W. H. Latham. *Certain improvements in machinery or apparatus for perforating and numbering paper or other substances to be employed as "tickets," or where other "counter registration" is required.* Dated March 12, 1862.

This invention consists in the combination of two machines, one for perforating the blank sheets to sub-divide it into the forms required, and the second part for numbering, the passage of the sheets being either continuous or separate. The apparatus for perforating consists of any number of discs arranged in pairs and sliding upon rotating triangular bars, the upper discs being provided with pins, and the lower discs having corresponding orifices in their peripheries, so that, as the paper or other material passes between them, the perforations are effected, the orifices receiving the pieces as they become punched out. It will be evident that this arrangement of machinery may also be employed for perforating in instances when numbering is not required. The apparatus for numbering being a second part of the invention, consists in the employment of a series of change rings, having the numerals projecting from the surface, and arranged as required, the unit ring being from 1 to 10, the rings having registering holes fitting on to pins on the shaft upon which they are arranged to insure precision; or it may be so arranged as to use flat bars of numerals placed side by side. The rollers for supplying ink to the said rings are moved by a cam and lever, so as to come into contact with the main ink roller, and transfer the ink to the projecting figures, the paper or material to be printed passing between them and a bed roller beneath.—*Patent completed.*

668. W. H. Latham. *Certain improvements in machinery or apparatus for cutting paper, pasteboard, and other similar substances.* Dated March 12, 1862.

This invention relates to that class of machines used for cutting paper wherein a vertical descending knife or blade is employed, and consists in imparting a motion to such blade which shall cause the blade to describe an entire circle from the commencement of its movement in descent to the completion thereof in its ascending course, by which means the patentee is enabled to obtain a better cut, and with cleaner edges of the paper or other material than hitherto. The motion is effected by means of cams, eccentrics, or cranks connected to the blade and actuated by a pair of worm wheels driven by worms on the driving shafts, no guiding or parallel bars being required.—*Patent completed.*

669. A. Watson. *Improvements in hot-pressing apparatus.* Dated March 12, 1862.

According to one modification of this invention, an improved plate is formed by taking two malleable iron plates, and forming counterpart grooves or channels in the inside face of each, in such a way that when the two plates are united together a continuous channel or channels is or are formed for the circulation of the steam or heated fluid. The combined plates are riveted or screwed together, and may be made water-tight at their edges by various means; but it is preferred to caulk the edges or to rivet one over the other; or a strip or layer of a compressible or elastic material, such as vulcanized rubber, may be introduced between the plates in a groove near the outer edge, or more or less over the surfaces. By these means a comparatively light and thin plate is obtained, whereby the heat may be applied rapidly and effectively. The improved means for introducing the steam or heated fluid into the plates consists of thin metal tubes attached to each plate by ordinary rigid screw couplings. These tubes are made with coils or bends, and of sufficient length to allow for the entire movement each plate requires, both during the pressing action and during the introduction and removal of the goods, the coils of bends giving the tubes the requisite amount or elasticity.—*Patent abandoned.*

670. J. Johnson. *Improvements in steam boilers.* Dated March 12, 1862.

In carrying out this invention the patentee makes the fire bridge hollow, of any suitable form to suit the flue, and places through the bridge any desired number of horizontal tubes of the multitubular class, and supports the said bridge by a vertical pipe or tube secured firmly to the bottom of the flue by rivets, screws, lock nuts, or other suitable means. When the bridge is under a junction pipe, or when required from any other cause, he connects to the tube at the top of the bridge a cross tube, and places it horizontally or transversely with the flue of the boiler, the said cross tube being secured in any suitable manner. When desired for sake of convenience and portability, he employs a flange joint between the bottom of the bridge and the bottom of the flue. He obtains additional heating surface by placing in the flue a double cylinder of any suitable length, and connecting it to the top and bottom of the flue by pipes or tubes communicating with the water in the boiler. The said double cylinder is made either with or without longitudinal tubes extending through it as may be required. He also places or fixes in the flue a number of tubes in a diagonal position longitudinally, and also cross tubes in connection or separately, for obtaining an increased heating surface and free circulation of water. He also employs a double cylinder, either with or without tubes for heating the feed water to the boiler, which double cylinder he places either in the back part of the flue, or connects it to the exhaust steam pipe, and passes through it the exhaust steam from the engine; the double-cylinder and hollow bridge are formed of welded wrought iron. *Patent completed.*

671. W. Conyers. *Improvements in currying leather.* Dated March 12, 1862.

This invention relates chiefly to rips, calf skins, and shoe hides, and the improvements consist in oiling them after the process of shaving and before the process of scouring, by which the pores of the skins are closed, and the tanning matter is prevented from escaping. Also, after the process of scouring and being hung up to "sam" or dry a little, they are stuffed on the grain side instead of the flesh side, whereby the process of whitening, as it is technically termed, is avoided. *Patent completed.*

672. E. Molyneux. *An improved method of utilizing the waste heat of the products of combustion as they escape from a furnace, and securing a more complete combustion of the fuel.* Dated March 12, 1862.

This invention consists in transferring the waste heat of the products of combustion, as they escape from the furnace to the air, which is supplied to support the combustion of the fuel by forcing (by means of a fan or otherwise) the hot products of combustion, and the air for supporting the combustion to pass alternately through a tube containing metal in a finely-divided state, such as perforated sheets of metal, wire gauze, or coils of wire. The hot products of combustion in traversing the tube are deprived of their heat by the finely-divided metal, and are then allowed to escape. The air for supporting the combustion is then admitted at the end of the tube from which the waste gases escape; as it travels onwards it takes up more or less of the heat that is left in the finely-divided metal, and is finally allowed to pass into the furnace. *Patent abandoned.*

673. P. Gondolo. *A new or improved baking-oven.* Dated March 12, 1862.

In carrying out this invention the patentee heats the oven by means of a metal or other retort, in which he burns coke by preference, combustion taking place by means of the air drawn by the furnace under the bars, and by reverberatory effects of the heating retort. This retort, which forms the furnace, is furnished with metal flues, circulating under the oven, and communicating with an open space surrounding it. The oven consists of a chamber of any suitable form of brick or metal, and completely closed, so as to prevent any products of combustion or heated air from entering, in such manner that the baking of the articles placed therein is effected solely by contact with the heated surfaces and by the radiation of heat. The furnace and its flues should be entirely free of any brickwork, so as to heat as much as possible the air which mixes with the products of combustion dispersing around the oven. The arrangement of the flues may be varied, or they may be entirely dispensed with, their purpose being to distribute in a uniform manner around the oven the heat and products of combustion which escape from the furnace. Dampers are also placed at each side of the furnace for directing the heat upon the sides, or for causing it to pass off at the dome. In order to retain the whole of the heat around the oven, he dispenses with the ordinary chimney, and thus has no draught nor entry of cold air. He, however, applies a small damper in one side of the brickwork surrounding the oven to afford an escape for the carbonic acid gas evolved in the combustion. *Patent completed.*

674. A. M. A'Beckett. *Improvements in railway signal apparatus.* Dated March 12, 1862.

The patentee claims the application of signal apparatus, in which a double cone, or other suitable surface, having patches in black and white, or otherwise in strong contrasts, put in motion by the passage of a locomotive engine and train, as and for the purpose described. *Patent completed.*

675. W. Clark. *Improvements in the manufacture of coloured inks.* (A communication.) Dated March 12, 1862.

This invention relates to improvements in the manufacture of red, blue, green, or violet inks, from pischine or analine. For this purpose the inventor dissolves a certain quantity of analine or pischine, according to the colour of the ink desired to be obtained, in a suitable volume of water. He then brightens the solution by means of alcohol, and thickens it with sugar or gum; the ink is then ready for use. The same bases derived from tar may be transformed by known processes into blue and green colours,

He employs such colours resulting from the transformation of analine for the manufacture of blue or green inks. *Patent abandoned.*

676. F. TOLHAUSEN. *A new toy, which he denominates "the colourimixt top."* (A communication.) Dated March 12, 1862.

This invention consists in so colouring the outer surface of tops that, when set spinning, they shall exhibit a pleasing combination of circular stripes of various colours, hues, and shades. *Patent abandoned.*

677. J. E. GRISSALE. *Improvements in photographic cameras and the mode of fixing the lens therein.* Dated March 12, 1862.

This invention relates to a peculiar construction and arrangement of folding or expanding and contracting cameras. In the improved camera the two ends are connected together on the four sides by an arrangement of the well-known "lazy tongs levers," which, consequently, admits of their being readily drawn nearer to or further from each other, whilst the parallelism of the back and front is preserved. These series of lazy tongs levers are braced together or strengthened by hoops or metal braces, which pass round and enclose them. The whole may be covered by the ordinary bellows covering, or by a bag. In lieu of the methods hitherto adopted for securing the lens tube into the front of the camera, which will allow only of one sized lens being used with one camera, unless a separate front be provided. and in lieu of using the "adapter," the inventor proposes to employ three or more pairs of radial flaps or arms, which are hinged or otherwise jointed at their outer extremities to the front of the camera, one set being placed outside and the other inside thereof. The inner ends of these flaps or arms converge towards the lens tube, and tend to hold it when made to approach each other in its proper central position, two rings on the lens tube, one of which is adjustable by the action of the hood or otherwise, serving as the lateral bearings for the ends of the arms or flaps. By this arrangement it is obvious that different sizes of lenses may be readily fitted into the same camera, the peculiar holding action of the arms or flaps always ensuring the proper central position of the lens. Suitable provision is, of course, made for excluding the light which would otherwise enter the camera when fitted with this arrangement for securing the lens. *Patent abandoned.*

678. E. G. FITTON. *Improvements in machinery for winding yarn or thread on to bobbins or spools.* Dated March 12, 1862.

This invention consists, first, in a novel combination and rrangement of mechanism, whereby the action, which in the ordinary machine drives the single spindle and regulates the winding on and pressing down, as above, of the thread on a single spool or bobbin, is applied to two or more spindles, and the spools or bobbins thereon in the same machine, by which means the operative is enabled to attend simultaneously to the winding on of as many spools or bobbins as there are spindles in the machine, instead of to one only. Secondly, in the application of a spring to each guide or presser used for guiding or pressing down the yarn or thread, whereby the necessity of pressing the guide by hand is obviated. Thirdly, in an arrangement of mechanism, wherein a series of pins, on one or more vertical bar or bars, raised and lowered by levers or other convenient means, act simultaneously on the girders or pressers, so as to lift and hold them up as required. Fourthly, in the application of an eye to the guide or presser, to prevent the yarn or thread flying off, and to increase the drag or friction on the threads in passing to the bobbin or spool. Fifthly, in the application or arrangement of mechanism, wherein a lever, brought into action by the foot of the attendant, moves one or more sliding bar or bars, to which a doffer plate is attached, so as to push the bottoms off the spindles. *Patent abandoned.*

679. W. E. NEWTON. *Improvements in the manufacture of cartridges.* (A communication.) Dated March 12, 1862.

This invention relates to a method of making cartridges with an envelope or covering of collodion instead of paper. In carrying out the invention a mould, composed of two parts, is employed. In this mould is placed the bullet, and on the top of that the powder, which is slightly compressed by means of a plunger introduced into the mould for the purpose. This pressure is applied simply for the purpose of causing the grains of powder to adhere slightly to one another, so that they and the bullet may be removed from the mould in one mass. The charge having been removed from the mould, and in order to make the bullet and powder adhere, a narrow zone or strip of collodion is run round the charge at the point where the bullet touches the powder. When the zone of collodion is hard, the charge or cartridges may be carefully lifted by the bullet, and dipped into liquid collodion of suitable consistence; and when the first coating is dry, the operation may be repeated, and a firm, strong, waterproof covering on the charge will be produced. *Patent abandoned.*

680. J. S. HENDY. *An improvement in the construction of chimneys and chimney-pots.* Dated March 13, 1862.

This invention consists in the construction of chimneys or pots of clay, metal, or other materials suited for chimney-pots, in such a manner as to intercept the downward current of air by the use of internal inclined plates or divisions, in connection with side openings in the chimney-shaft or pots, for the introduction of air deflected upwards in such manner as to assist the inner upward current in repelling the downward current of external air, so that by means thereof the inner upward current may be maintained or assisted, and the downward current may be checked or effectually counteracted. This is effected by introducing into the chimney-shaft or chimney-pot openings in two opposite sides thereof, at the foot or junction of one inclined plate or surface across the chimney or chimney-pot, for turning or deflecting the current of external air entering through the said openings upwards. *Patent abandoned.*

681. F. H. FONTAINE. *A process of reproducing all sorts of photographics, drawings, paintings, and engravings engraved on metal, which he calls "Chalcopantographic."* Dated March 13, 1862.

In reproducing engraved plates by negative stereotypes, the inventor pours upon a zinc plate a solution composed of distilled water, two ounces; gelatine, about one quarter of an ounce; and saturated solution of bichromate of potash, about one fifth of a cubic inch. When dry, he places the gelatinous surface of the plate in contact with the printed side of the negative stereotype on glass or paper of the drawing to be reproduced, exposing it to sun-light about seven minutes, or diffused light about twenty minutes. He then removes the zinc on which the negative stereotype will now be apparent, and immediately places it in a basin of luke-warm water to dissolve the bichromate, and in a few minutes the picture will appear engraved in depth sensible to the touch. He then drains the plate and sponges it with tissue paper; then pours upon the picture or impression a solution of gallic or peragallic acid, and again washes the plate. He now has a stereotype, the hollows or cavities of which are solidified. He takes an impression from this by pouring on the stereotype dissolved and thoroughly-purified gutta percha; and when this is dry, he takes a cake of pure gutta percha (a little larger than the stereotype), which, in its preparation, has been melted with about three times its weight of linseed or other thick drying oil. The surface of this cake is heated by a red-hot iron, and applied on the stereotype in such wise that the coat of purified gutta percha already on the stereotype unites with the cake. He submits the whole to pressure, and permits it to cool. He then removes the pressure, and the solidified stereotype being incompatible with the gutta percha, it follows that he easily detaches from the primitively engraved stereotype a second one in gutta percha, which reproduces the picture or engraving in relief. After having submitted the gutta percha stereotype to the requisite preparations, he places it in a galvanic bath, and thus obtains an engraved copper plate, reproducing the original with exactness, and in such reduced proportions as may be desired. *Patent abandoned.*

682. L. VIDIE. *Improvements in the construction of aneroid barometers, partly applicable to steam gauges.* Dated March 13, 1862.

We cannot here give space to the voluminous details of this invention. *Patent completed.*

683. J. CUNNINGHAM and R. CUNNINGHAM. *An improved ornamental fabric and improvements in weaving and in jacquard apparatus.* Dated March 13, 1862.

The patentees claim the producing of an improved ornamental fabric, and the introducing of improved weaving arrangements for the production of ornamental fabrics, substantially as described; also the contriving of jacquard apparatus, so as, by a mere shift of the draught board or grater relatively to the cords or wires, to cause the pattern to be worked to either side of the fabric, substantially in the manner described. *Patent completed.*

684. J. HUNTER. *Improvements in apparatus for removing slag from furnaces.* Dated March 13, 1862.

This invention is designed to obviate the loss of time hitherto experienced in removing slag from furnaces, and the destructive wear and tear of the boggies or waggons employed therein. In carrying out the invention, according to one modification, the top or platform of the boggie is made hollow or cellular to receive water, by the circulation of which it is kept cool and prevented from becoming distorted and damaged from the heat of the fresh slag. To receive the slag the boggie is placed under a kind of enclosure, the three sides of which consist of cellular or hollow casings, fixed upon pillars or other supports, whilst the fourth side is closed by doors also made cellular or hollow. The slag is run into this box or enclosure, and upon the boggie, and when it is sufficiently cool to retain its shape (this being attained more rapidly than hitherto) the doors are opened, and the boggie is drawn away with the block of slag upon it. To facilitate this removal the enclosure is slightly narrowed from the doors towards the back. Various arrangements may be made for directing the circulation of the water. Two or more water casing enclosures may be fitted up in juxta position, with provision for receiving and filling two or more boggies at one time. *Patent completed.*

685. G. ERMEN. *An improved receptacle or case for the protection of threads of cotton, silk, or other fibrous substances when in a "spooled," "balled," or otherwise wound state, or for the reception of tapes.* Dated March 13, 1862.

This invention relates principally to such threads as are wound upon spools or bobbins, or in the form of balls, or are produced in other convenient forms for use, and generally known as sewing thread, the object being to protect the thread from soiling and entanglement whilst being unwound, and to provide a permanent case for the thread when not in use. For this purpose the patentee employs a case or receptacle subdivided into compartments, each compartment being for the reception of a separate ball, bobbin, or spool, somewhat similar in description to an ordinary work-box, such case being closed by an outer lid or cover. Now, this invention consists in the interposition of an inner lid between the top of the partitions and the outer lid, such inner lid having perforations or slits therein for the passage of the thread or tape, and, consequently, corresponding in number to the number of compartments, so that the inner perforated lid closes the compartments, and the threads project through the perforations; and when not in use the outer cover is placed on, and such ends are protected from withdrawals; or the outer case may be perforated, and the inner one dispensed with; or, if preferred, the threads may pass out of the sides of the case. *Patent completed.*

686. H. FLETCHER. *Improvements in cleaning and preparing cotton, and the machinery used for that purpose.* Dated March 13, 1862.

The Indian Churka is used for separating the seed from the cotton. The inventor furnishes it with a hopper or feeder, and a diaphragm to keep the seed from the cotton. He covers the rollers with metal cylinders, and makes one larger than the other. He applies metal spindles to work in metal bearings, which may be attached to the wood frames. He substitutes weighted levers for the wooden wedges used to gain pressure, or a light metal frame and springs may be used instead of wood. He improves the American roller gin by using rollers covered with metal cylinders, and gains pressure by springs, heavy fly-wheels, or weighted levers. In one form he makes the top roller the largest, and feeds by an aperture at the top, which regulates the quantity of cotton presented to the roller, which draws it to the smaller roller, a cover and grating being used to protect the cotton and part with the seeds. When it passes twice through the roller, he adds a third roller, which may help to straighten the fibres by going faster; or it may have small pins on its surface to draw out the fibres after the seed has been separated, and pass the fibres over a grid, where a blower removes sand and impurities. A series of rollers may be used to clean and straighten the fibres, so that they may not be injured in the packing. The three rollers may be made double acting by having a double feed, the smaller roller acting on each of the larger ones. *Patent abandoned.*

687. J. WADSWORTH. *Improvements in the construction and manufacture of movable and adjustable heels for boots and shoes.* Dated March 13, 1862.

This improved mode of manufacturing movable or adjustable heels for boots and shoes, consists first, in means of stamping and compressing sheet metal in suitable dies, and completing the construction of the metal parts of the same by knurling or milling. Secondly, in the construction of the improved movable heels with a central boss or bearing, in which there is a spring attached to a separate plate. Thirdly, in the employment of wood boiled or steeped in oil in combination with leather, as the material whereof the wearing parts of such movable or adjustable heels are composed. *Patent completed.*

688. J. HOWARD and J. BULLOUGH. *Improvements in warping and beaming machines.* Dated March 13, 1862.

This invention relates to a self-acting stopping motion, that is to say, a means of stopping the warping or beaming machine when one or more of the warp threads break, by by means of a current of electricity. The electric spark or current acts upon a magnet which is in connexion with a catch or knocker-off piece. Each thread of the warp supports, which, when so supported, can only touch one of two conducting surfaces, connected respectively by wires to the negative and positive poles of the battery. The moment a thread breaks, its pin falls on the other conducting surface, and thus forms a connecting link betwixt the two poles. The electric current thus established charges a magnet, which, by attracting a catch or other suitable agent, brings the knocking-off piece into action. The thread being pieced again supports its pin above one of the conducting surfaces, thereby breaking the connexion betwixt the two poles, so that the magnet, having lost its power, cannot attract the agent which brings the knocker-off into action, and so the machine continues working until another thread breaks, and allows a pin to fall, which acts in the manner above described and stops the machine. *Patent abandoned.*

689. E. T. HUGHES. *Improvements in furnaces for consuming smoke.* (A communication.) Dated March 13, 1862.

This invention is not described apart from the drawings. *Patent completed.*

690. S. V. BONNETERRE, C. T. ERHART, and J. F. MONTI. *An improved apparatus for regulating the pressure of steam in steam boilers and the combustion in their furnaces.* Dated March 13, 1862.

The object of this invention is to regulate the pressure of steam in steam boilers, and the combustion in their furnaces, in such manner that they (the pressure and combustion) shall act upon each other, and be thereby mutually regulated one by the other. For this purpose the patentees employ a vessel with flexible sides communicating with the boiler; when the pressure of steam in the boiler increases the vessel expands, and when the pressure becomes reduced the vessel is contracted, and by these actions a valve, damper, or similar mechanical contrivance is closed and opened, thereby reducing or increasing the draft of air to the fire, and regulating the combustion accordingly. *Patent completed.*

PROVISIONAL PROTECTIONS.

Dated May 19, 1862.

1516. T. Morris and R. Weare, Birmingham, electricians, and E. H. C. Monckton, of Fineshade, Northampton, Esquire. Improvements in obtaining and applying light and heat by electricity.

Dated May 23, 1862.

1562. A. Samuelson, 28, Cornhill, engineer and iron ship builder. Improvements in the working of hydrostatic presses, and in the apparatus employed therein.

Dated July 29, 1862.

2154. E. B. Clark, Lower Polgooth, St. Ewe, Cornwall. Improvements in the manufacture of candles, and in apparatus employed therein.

Dated August 7, 1862.

2211. A. Thiriez, Lille, France, manufacturer. A new machine for glossing and glazing all thready fabrics.

Dated August 11, 1862.

2244. J. Lancelott, Birmingham, jeweller. Improvements in the manufacture of ornamental chains for sheet metal.

Dated August 21, 1862.

2339. A. Boubée, Paris. Improved apparatus for casting or moulding glass, and imitating precious stones or marbles.

Dated August 27, 1862.

2371. G. Davies, 1, Searle-street, Lincoln's-inn, civil engineer. A machine for singeing woven fabrics of cotton, wool or silk by means of gas or alcohol. (A communication.)

Dated August 29, 1862.

2401. W. Owen, Rotherham, engineer. Improvements in the manufacture of railway wheels and tyres, and in securing tyres to wheels.

Dated August 30, 1862.

2410. J. H. Johnson, 47, Lincoln's-inn-fields, gentleman. Improvements in coating or covering metallic surfaces with copper. (A communication.)

Dated September 1, 1862.

2412. J. G. N. Alleyne, Butterley Iron Works, Alfreton, Derby, and J. Roberts, 3, Essex-court, Temple, Captain in the Royal Marine Artillery. Improvements in the manufacture of flanged wrought iron or steel plates, and of wrought iron beams and frames of a trough-shaped section, and in the apparatus employed for that purpose.

2418. E. G. Fitton, Ardwick, Lancaster, machinist. Improvements in machinery for winding yarn and thread on to bobbins or spools.

Dated September 2, 1862.

2425. J. Mosheimer, Manchester, chemist. Certain improvements in machinery for amalgamating gold and silver or the ores thereof.

Dated September 4, 1862.

2448. H. L. Emery, Foulis-terrace, Brompton, agricultural implement maker. Improved machinery for ginning cotton.

Dated September 5, 1862.

2462. W. E. Bovill, 22, James-street, Buckingham-gate, civil engineer. An improvement in the mode of applying oil and other fluid lubricating matters to machinery.

Dated September 8, 1862.

2474. J. Whitehead, David-street, Manchester, commission agent. Certain improvements in looms for weaving.

2472. J. Hartshorn, Mansfield-road, Nottingham, lace manufacturer, and W. Redgate, Nottingham, draughtsman. Improvements in means or apparatus for the manufacture of lace fabrics.

2473. C. Fink, Berlin, professor of mechanics. An improved turbine.

2474. G. W. Belding, 7, King-street, Cheapside, Improvements in wringing machines. (A communication.)

Dated September 10, 1862.

2484. J. Saunders, 7, Mordin-place, Lewisham-road, engineer. Improvements in lamps.

2486. M. Smith, Heywood, machine maker. Improvements in machinery for raising the nap on woven fabrics. (A communication.)

2488. F. Hands, gentleman, and H. Holland, Birmingham, black ornament maker. New or improved compositions for the manufacture of black ornaments, such as brooches, bracelets, ear-rings, and other ornaments usually made of jet, which said compositions may also be applied to the manufacture of various other articles.

2490. A. Barclay, Kilmarnock, engineer. Improvements in traction engines, and in apparatus for indicating the pressure of steam.

2492. G. T. Bousfield, Loughborough-park, Brixton. Improvements in machinery used in the manufacture of files. (A communication.)

2494. G. T. Bousfield, Loughborough-park, Brixton. Improvements in machinery for cutting files. (A communication.)

Dated September 11, 1862.

2496. T. Steel, Bradford, York. Improvements in treating soap-suds or other saponaceous or oily matters.

2498. C. R. Humphrey, 69, Old-street, St. Luke's, engineer and machinist. Improvements in printing machinery.

2502. W. Clark, 53, Chancery-lane, engineer. Improvements in cigar and cigarette cases. (A communication.)

2504. J. Thomson, Seafield-works, Dundee, spinner and manufacturer. Improvements in the treatment of vegetable fibres with a view to their manufacture into textile fabrics.

2506. W. Richards, Birmingham, gun manufacturer. Improvements in fire-arms and cartridges.

2508. P. Ward, 2, Cloud's-hill-villas, St. George's, Bristol. Improvements in the manufacture of a double sulphide of calcium and sodium.

2510. A. Whytock, Landsdowne-terrace, Gloucester-road North, Regent's-park, galvanized iron merchant. Improvements in the construction of coated and uncoated sheet-iron boxes, and in the mode of and apparatus for straightening coated and uncoated sheet iron.

Dated September 12, 1862.

2516. J. Rowell, Aberdeen, manufacturer. Improvements in pillars and apparatus for straining wire.

2518. A. J. Moreau, Sherborne-street, Blandford-square, chemist. An improved mode or process for reducing or melting pulverized metals or metallic ores.

Dated September 13, 1862.

2522. H. J. Lewis, Birmingham, engineer. Improvements in engines to be worked by means of water.

2524. W. J. Williams, Arundel-street, Strand, merchant. Improved apparatus or machinery for punching, cutting, or pressing metal or other plates or substances, which said improvements are also applicable to tension rods.

2526. A. V. Newton, 66, Chancery-lane, mechanical draughtsman. An improved mode of and apparatus for sleeking, creasing, and raising leather. (A communication.)

2528. W. Palmer, Sutton-street, Clerkenwell. Improvements in lamps and in apparatus used therewith.

Dated September 15, 1862.

2530. W. G. Rawbone, Birmingham, gun manufacturer. Improvements in gun barrels, and in machinery to be employed in effecting the said improvements, and in tools and machinery for producing inscriptions, ornaments, and devices upon gun barrels, lock plates, and other metallic parts of small arms, and for producing inscriptions upon saws and articles of cutlery generally.

2532. E. Balmforth, Albion Mill, Batley, York, millwright and machine maker. Improvements in machinery employed in finishing texile fabrics, commonly called "raising gigs."

2534. H. M. Radloff, Limehouse, oil refiner. An improvement in vessels for filtering oils.

Dated September 16, 1862.

2538. B. F. Weatherdon, Kingston-upon-Thames, civil engineer, and E. H. C. Monckton, Fineshade Abbey, Northampton. A new or improved engine for obtaining and applying motive power.

2544. R. Lakin, Ardwick, machinist. Improvements in the mode of plating or shielding ships of war.

2546. C. E. Guye, Fleurin, canton Neuchatel, Switzerland, watch maker. Improvements in apparatus for cutting and finishing the teeth of wheels. (A communication.)

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

1472. J. Wright. Improvements in machinery for digging, excavating, and removing earth. (A communication.)

1483. C. Binks. Apparatus for treating linseed.

1493. B. Sharp. Construction of ships and vessels.

1496. C. Binks. Obtaining oxygen and chlorine gases.

1500. J. Hogg, jun. Book covers.

1508. J. Wright. Sheathing iron or metal ships.

1509. J. Eastwood. Machinery or apparatus for removing and wringing hanks of thread.

1510. R. Ramsden. Machinery or apparatus for mashing malt.

1515. T. Morris, R. Weare, and E. H. C. Monckton. Protection of life and property.

1516. T. Morris, R. Weare, and E. H. C. Monckton. Obtaining and applying light and heat by electricity.

1517. M. A. F. Mennons. Breech-loading fire-arms. (A communication.)

1523. J. Taylor. Abstracting heat from liquids.

1530. J. Hopkinson. Pianofortes.

1535. A. Giles. Constructing floating breakwaters.

1539. J. Oxley. Making wheels.

1540. C. W. Siemens. Electric telegraph apparatus.

1542. E. De la Bastida. Production of designs. (A communication.)

1543. G. Crawford. Musical instruments.

1544. J. Needham. Breech-loading fire-arms.

1550. H. Cook. Electric batteries. (A communication.)

1551. W. Roberts, and T. Greenacre. Cocks or valves.

1554. P. McGregor. Spinning and doubling fibrous substances.

1557. W. E. Wiley. Penholders.

1560. E. Mouline. Apparatus used in weaving.

1562. A. Samuelson. Hydrostatic presses.

1563. W. Clark. Manufacture of socks and stockings. (A communication.)

1565. J. Harrison, and R. Parkinson. Rollers for preparing, spinning, doubling, sizing, winding, warping, and weaving.

1566. W. and J. Harrison, J. Oddie, and W. Parkinson. Machinery for winding, sizing, and weaving.

1569. M. Walls, and J. Crompton. Railway signals.

1570. J. Taylor. Preparing fibrous materials to be spun.

1572. W. Clark. Manufacture of buttons. (A communication.)

1574. J. A. C. N. Delpech. Pumps.

1584. J. Halliday. Manufacture of ornamental trimmings.

1585. J. Ireland. Moulds for card cylinders.

1609. J. A. Ransome. Manufacture and fastening railway chairs with wood treenails.

1614. G. Ashton. Dying fibrous substances.

1616. W. Perks. Metallic sash bars for windows, skylights.

1643. R. Shortrede. Presses for pressing cotton and other articles.

1655. J. King. Looms.

1677. A H. Perry. Fastening together or securing railway chairs and sleepers.

1707. W. R. Jeune. Manufacture of fabrics.

1719. J. M. Ryo-Catteau. Twisting fibrous threads.

1738. W. Holland. Carding engines.

1753. B. George. Construction of portable beds, bolsters, pillows, and sofa and other cushions.

1801. W. E. Newton. Electrical brushes. (A communication.)

1810. M. Wiggell. Bolts and fastenings for shipbuilding.

1955. J. Kidd. Gas meters.

1975. J. Rhodes. Rag machines. (A communication.)

2062. A. Cotelle. Manufacture of alcohol.

2121. T. Sagar, and J. Roeliff. Moulding.

2154. E. B. Clark. Manufacture of candles.

2215. R. A. Brooman. Covering ships with a backing of wood. (A communication.)

2412. J. G. N. Alleyne, and J. Roberts. Manufacture of flanged wrought iron or steel plates.

2426. W. Hunt. Manufacture of muriate of ammonia.

2431. J. B. Thomson. Electro-magnetic machines.

2445. B. F. Cowan. Cannon and other fire-arms.

2492. G. T. Bousfield. Manufacture of files. (A communication.)

2494. G. T. Bousfield. Cutting files. (A communication.)

2506. W. Richards. Fire-arms and cartridges.

2526. A. V. Newton. Apparatus for sleeking, creasing, and raising leather. (A communication.)

The full titles of the patents in the above list can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list who have given notice of their intention to proceed, within twenty-one days from the date of the *Gazette* in which the notice appears, by leaving at the Commissioners' office particulars in writing of the objection to the application.

PATENTS ON WHICH THE STAMP DUTY OF £50 HAS BEEN PAID.

2202. C. Stevens.
2188. P. J. L. Chaumont.
2184. C. Cowper.
2221. J. H. Johnson.
2249. J. Rawlings.
2204. T. Allan.
2235. E. Morewood.

PATENTS ON WHICH THE STAMP DUTY OF £100 HAS BEEN PAID.

2129. J. Beattie.
2168. J. Good.
2175. J. Beattie.

LIST OF SEALED PATENTS.

Note.—Specifications will be forwarded by post from the Great Seal Patent Office (publishing department) on receipt of the amount of price and postage. Sums exceeding 5s. must be remitted by Post Office Order, made payable at the Post Office, High Holborn, to Mr. Bennet Woodcroft, Great Seal Patent Office.

Errata.—In our notice last week of "Iron Manufacture," the word "hæmatite" was unfortunately misprinted, "hexmatite" on each occasion of its occurrence; "magnitu" was substituted for "magnetic," and one or two other minor typographical errors also inadvertently showed themselves.

TO CORRESPONDENTS.

Received—T. F. Y., R. L., S. P., W. A., Viator. "Viator" in our next. Fluid resistance in our next. St. J. V. D. in our next. W. P., R. H. D., J. H., W. W., Capt. P., W. H. S., D. M.

A trial is ordered by the Admiralty to be made at Portsmouth of a stern rudder constructed on the patented plan of a Mr. Lumley. The peculiarity of the rudder consists in its being cut in two vertically, and the two parts being connected together by gudgeons and pintles in a manner precisely similar to the ordinary method of hanging a rudder to a ship's sternpost. At the outer part of the rudder's afterpiece are attached two chains, which pass through the main piece of the rudder, one on each side. The result of this arrangement is that on the rudder being moved over, either to starboard or port, the chain becomes taut, and brings the outer piece of the rudder over at a sharper angle than the main piece, and thus presents a hollow surface to and obtains a greater hold on the water than can be obtained with the ordinary rudder, and without bringing any very great strain to bear upon the gudgeons and pintles.

THE
MECHANICS' MAGAZINE.

LONDON, FRIDAY, OCTOBER 10, 1862.

PLATE-WORKING MACHINERY AT THE INTERNATIONAL EXHIBITION.

GIVING our foreign guests precedence, from international courtesy, we find that M. Tussaud, of Paris, shows a small shearing machine, with revolving cutters, for plate up to 4 inches thick. This, we believe, has been patented in England. The gearing in this machine is carried out, away from the cutters, which are, by extending their spindles, left free at the back, thereby allowing of a great breadth of plate to be cut. There would be no limit to this breadth if the cutters were worked by bevil-gearing. This appears a very ingenious way of getting over the difficulty found in most shearing machines, of taking in a great breadth of plate. It is, no doubt, a good plan if the machine be used for straight shearing merely, but its efficiency is diminished for cutting out curves or circles, as the frame carrying the cutters necessarily blocks up one side of them. The workmanship is very inferior. The Americans seem too busy at punching and shearing themselves to send any machine of the kind to the Exhibition.

Austria exhibits two small hand-lever shears, and a punching machine with six quarter-inch punches for 3-16 plate,—neither of these deserving but little notice. Horak, of Vienna, shows a little machine for punching out coffee strainers, for which he obtained a medal. It consists of four small punches, worked up and down in a frame, while the plates are being rotated underneath by a self-acting motion. The centre hole to fix the strainer down is first made by hand.

Spain sends a small double punching machine, Mr. De Bergue, of Barcelona, being the exhibitor. It appears as a "pressing machine" in the Official Catalogue. It is on the well-known model of the Manchester machine by the same firm, but seems to be disowned by the English branch on account of its rude workmanship. This is the only machine sent by Spain.

Messrs. Whitworth, and Messrs. Sharp, Stewart and Co., of Manchester, and Messrs. Buckton, of Leeds, show large punching and shearing machines, direct acting, with eccentric and slides. In Whitworth's machine for punching holes in 1¼-inch plate, and shearing up to the same thickness, taking in 18½ inches, the power is got up by a single large wheel, so that all the strain is on one tooth. The framing is cast in two pieces, and, to fully carry out the "dualistic" principle, he has two fly-wheels. The stroke of the punch can be varied—a very useless addition. The stop motion for the punch is very defective, as it requires several turns of a handwheel to throw the punch out of gear, and this wheel, again, is out of reach of the man using the punch. It is easily seen that Mr. Whitworth does not make steam boilers in his workshops.

Sharp, Stewart, & Co.'s machine for punching and shearing 1¼-in. plates is well shaped, and is in every respect much superior to Mr. Whitworth's. The shears are at an angle for bar cutting. It does not, however, seem very convenient for working angle iron.

The machine of Messrs. Buckton punches 1¼-in. holes in 1¼-in. plates, and shears up to the same thickness, taking in 24 in. from the centre of the punch and edge of the shears. These are at an angle for cutting bar iron, and there is, besides, a knee joint arrangement for cutting up to 6-in. angle iron. The machine is well arranged for punching and shearing angle iron. The framing is in one rather rough casting. The lower blade of the shears is lengthened out to bear up the plate conveniently.

Nasmyth & Co., of Patricroft, show a self-acting dividing and punching machine for hole in any length of plate up to 10 feet 9 in. The plate to be punched is placed upon a table similar to that of a planing machine, and is worked underneath the punch by a very ingenious self-acting motion, which can be easily altered to suit a different pitch of rivets. The eccentric working the slide of the punch is driven by an independent engine, of the Patricroft steam-hammer design, at the back of the machine.

Fairbairn & Co., of Leeds, show a small portable shearing machine, on rollers, for either hand or steam power, with circular cutters, shearing up to ⅝-in. plates, with a stud in a grooved table for cutting circles. This will only take in 7 in. from the edge of cutters.

Hulse, of Manchester, has a neat small punching and shearing machine, on rollers, to punch a ⅝-in. hole, shearing a ½-in. plate, and taking in 9½ in. It has the usual fault with machines having the punching and shearing on the same side—that of the shears being too high for the convenience of the operative.

Hunt, of London, has a very elegant hand machine for punching and shearing 5-16 in. This little machine is very well arranged, but it might be improved by placing the shears at an angle.

Rhodes, of Wakefield, exhibits a small punching and shearing machine, for plate ⅝ in. thick, and taking in up to 8 in. Its slides are worked by two levers, the ends of which are caught at the top by a separate eccentric and catch to each. Much gearing is thus dispensed with—a great gain in any machine, and especially so in this particular kind of machine tool, as shreds of the plate being cut are so liable to get into the wheels and break the teeth. The shears are at an angle for bar cutting. This machine seems to contain within itself the elements of a good punching and shearing apparatus. The general idea might be carried out in a larger-sized machine; and, worked by two cams instead of the present eccentrics, would give the irregular motion of the punch so much liked by boiler-makers, as they thereby have time given them to set the plate properly under the descending punch. A stop motion to throw the punch out of gear is then not so much required.

De Bergue and Co., of Manchester, exhibit two punching and shearing machines. The large size one is driven by a small steam engine attached to its framing. The ordinary slides are dispensed with in these machines, as it is worked by a triangular lever, somewhat similar to the so-called "T bobs," for large mining pumps. This triangular lever is caused to vibrate at the top by an eccentric in a slide, and it punches and shears at the other two corners of the triangle, vibrating on a bearing between these two. The larger machine has a very elegant and symmetrical appearance. The punches are fitted with a small nipple on the face, which in the process of punching fits into a centre punch mark in the plate to be punched. When punching holes in a straight line at a uniform pitch, a pointer is attached to the machine, so adjusted that the distance of its point from the centre of the punch equals the pitch of the holes to be punched. This pointer, in the process of punching, drops into the centre punch indentations, indicating to the workman that the adjoining indentation is exactly under the centre of the punch. By means of this apparatus, in addition to greater accuracy, more work is got through. As many as 16 holes a minute can be punched by this machine. It is capable of punching 1¼-in. holes through 1¼-in. plates 21 inches from the edge, or discs 7 in. diameter through ¾-in. plates. The machine admits of the punching-head being reversed, if it be required to punch holes in large plates, at a greater distance from the edge. The punching-head and die-holder may also be taken away, and replaced by apparatus for rivet making. The second size machine is similar in principle, but slightly different in design. It is single-geared only. It is fitted with stop motion and pointer similar to the large punch above-mentioned. This stop motion is instantaneous, and very convenient to the workman, a mere touch of the handle being all that is required to throw the punch loose, and out of gear. The fact of the punch in this machine moving through an arc of a circle is not such a disadvantage as it would at first appear; because, as most people will have observed, the punching of any plate is in reality effected long before the punch is down; the sharp snap of the driven-out disc of metal is often heard before the punch is half through.

Messrs. De Bergue also exhibit a riveting machine for girder work, driven by a belt, the motion being transmitted through double gear to an eccentric shaft, which alternately forces forward and draws back, by means of a connecting rod, a hollow cylindrical carrier, holding a plunger, in which is fixed the heading die. The opposite die is held in the end of a strong steel screw, fitted into a bush in the pillar which receives the thrust in the process of riveting, the use of the screw, which is squared at the outer end, being to adjust the distance between the dies for various thicknesses of plate. This machine is also fitted with a stop motion similar in principle to the one on the punching machine, by means of which it is protected from injury should the plunger, in advancing, come in contact, by accident, with a cold rivet, the edge of an angle bar, or other impediment sufficient, in case no provision were made for such a contingency, to break down the machine.

This machine is capable of heading rivets up to 1 inch in diameter, and at the rate of about 16 per minute, and, including all stoppages, its average has been from 3,500 to 5,000 rivets per day of ten working hours. This, compared with the old system of handwork, is equivalent to from 17 to 25 sets of riveters, each set comprising three men and a boy.

The angle bar, cutting, or scrap-cutting machine, also exhibited by this firm, is similar in principle, so far as the eccentric and large punching gear are concerned, to the shearing machines. It is also a very fine looking machine, and is capable of cutting bars 6 inches by 1¼ inches in thickness.

It is to be regretted that a connected series of boiler-making machinery is not in the Exhibition. Plate-bending machines are not at all represented. A good, simple machine of this kind for flues, chimney-plates, &c., is rather a desideratum.

Engineers are now pretty well agreed amongst themselves that perforating plates by punching very much weakens them. Anyone can see that such a process must very much "punish" a plate. It is possible that in the International Exhibition of 1872 there may be no boiler-plate punching machines, as engineer's customers may have learnt by that time to specify drilled rivet holes.

PHILOSOPHICAL AND MATHEMATICAL INSTRUMENTS AT THE INTERNATIONAL EXHIBITION.

We last week took occasion to remark upon the display of horological instruments in the north-east gallery of the Exhibition, and as being nearly allied to them in character, and located in the same part of the building, we intend devoting some attention this week to the show of philosophical and mathematical apparatus. It is almost unnecessary to say that during the last few years immense improvements have been made in this particular branch of mechanical science. Those who were fortunate enough to see the Exhibition of 1851, and who took any interest at all in the philosophical instrument department of it, cannot fail to remark, while examining the present display, the great advancement which, during the intervening eleven years, has been effected. The comparison is, indeed, fraught with the most gratifying sensations, for while we know that scientific discovery in this country has progressed with wondrous rapidity during the period named, we see also that mechanical skill and industry have more than kept pace with it, and supplied in abundance the necessary adjuncts and aids for pushing discovery still further. Assuredly, therefore, no apology is needed on behalf of the representatives in the International Exhibition of the philosophical and mathematical instrument branches of the mechanical trades of the United Kingdom. Their works speak for themselves, and eloquently tell also of the thought, ingenuity, and skill of those who contrived and manufactured them. Indeed, the universal excellence of the various scientific contrivances of the description under notice, renders the task of selecting individual ones for especial comment arduous and difficult. We must beg of those exhibitors, therefore, who may fail to obtain "honourable mention" at our hands, to attribute the fact, not to want of will or discernment, but to the physical impossibility of doing justice to all claimants.

As being in these stirring times, when other nations are striving for maritime superiority, and an increased knowledge of nautical science of most immediate interest to our readers, we shall first speak of such appliances as have reference to oceanic discovery. Foremost among these are the instruments invented by Mr. Henry Johnson, of 39, Crutched-friars, and manufactured by Mr. Hoffman, of Wilmington-square, Clerkenwell. They consist of deep-sea pressure gauges, and deep-sea thermometers. It has been long known from actual experiment, confirmatory however of scientific theory, that in deep-sea soundings the pressure of water is too great to admit of accurate measurement, by the compression of any elastic fluid confined in a small portable instrument. For a long time water was considered incompressible, but, as shown clearly by Mr. Glaisher, F.R.S., in a paper read by him before the British Association, it has been found to possess a slight degree of elasticity, sufficient, indeed, to render its compression available as an indication of the density of the water into which it is lowered. Without going into detail, as to the various efforts which have been made during the last half century to produce efficient instruments for the purpose of measuring the density of the ocean at great depths, it may be stated that most of them had, up to the time of the inventions of Johnson's pressure-gauge, proved complete failures. In experiments made with metal pressure-gauges, it was found, for example, that air bubbles adhered to their inner surfaces, and materially interfered with the results.

The deep-sea pressure-gauge of Mr. Johnson consists of a cylindrical glass vessel with a long neck, or stem, finely graduated. The material used in this case, therefore, allows of an inspection of the interior, and the absence of air bubbles may thus be assured before any experiment is made with it. It would be difficult, without diagrams, to describe exactly the construction of the apparatus. It must suffice to say that it appears to be admirably adapted for the effecting the object sought, and that the probability of its derangement when in use is small indeed. The deep-sea thermometer of the same exhibitor is intended to be employed in conjunction with the gauges. It is composed of solid metals of considerable specific gravity—namely, brass and steel. They are, therefore, not liable to compression by water, which, under a pressure of 1,120 atmospheres, or at a depth of 5,000 fathoms, in round numbers, acquires a density of specific gravity of 1·06 only. In the construction of this instrument advantage has been ingeniously taken of the well-known differences in the ratios of expansion and contraction by heat and cold of the two metals named. Compound bars formed of these slips of brass and steel are riveted together, and this bar is found to assume a slight curve in one direction, when heat has expanded the brass more than the steel, and a slight one in the contrary direction, when cold has contracted the brass more than the steel. These changes are registered by the instrument itself, and in testing one for six months by standard meteorological instruments, Mr. Glaisher found that the readings of the deep-sea thermometer approximated closely to those of the standards used. It is needless to expatiate on the value of such contrivances as those of Mr. Johnson. All naval officers will at once recognize it, and the Admiralty no doubt are cognizant of the importance of the inventions—at least they should be so.

The Submarine Telegraph Company exhibit samples of their various continental submarine cables, which are in working order. These samples are of different sizes, and represent in the aggregate a submarine conductor of 2,777 miles in length. It is not necessary to describe the peculiar formation of each cable, because our own readers are probably for the most part quite conversant with the general formation of submarine conductors. We need not urge either a consideration of the progress made in submarine telegraphy since the year 1851, because our own pages have continuously recorded that progress, and shown alike the strong and the weak points of the science. Messrs. Yeates and Sons, of 2, Grafton-street, Dublin, exhibit largely and successfully, and their works comprise astronomical, meteorological, philosophical, and mathematical instruments. Two equatorially-mounted telescopes, supported by iron columns, are perhaps the most remarkable portions of the display made by this firm, as they certainly are the most conspicuous. The mounting possesses many improvements in detail. The clamping circles are quite independent of the divided circle, and are placed at the opposite ends of their respective axes. The clamping circle of the polar axis is directly under the northern pivot, and that of the declination axis close to the telescope. The clamping arrangement also differs from that in general use at present, as being far more effective and free from torsion. The smaller stand of the two appears to be well adapted for those who have no convenient space to erect an observatory upon. The iron column, for example, may be permanently fixed in the open air, whilst the equatorial arrangement packs compactly in a small box, from which it may be lifted into its place on the top of the column in a few minutes, without its adjustments being materially affected.

The Elliptograph of Messrs. Yeates & Sons is another instrument whose name implies its use. This differs in three essential points, however, from all other elliptographs in use. Firstly, there is no limit whatever to the variation in the proportions of the ellipses formed by it. Secondly, it offers great facility for setting it to draw any ellipse whose major and minor axes are known; and, thirdly, it gives more accuracy to the figures formed by it in all proportions—at least, so say its inventors. Of its ingenuity of construction, at any rate, there can be no doubt. The large public barometer exhibited by this firm, the dial of which is three feet in diameter, and their public thermometer, with a dial of the same dimensions, are remarkable illustrations of the willingness of Messrs. Yeates and Sons to meet the wants of the present day. In agricultural districts and fishing towns it is easy to comprehend that such instruments would be especially useful, and indeed vitally important, to the inhabitants.

Telegraphic implements or apparatus are, we need not say, presented to our notice at every point in what may be called, for the sake of brevity, the philosophical instrument court. But as in former papers on the Exhibition much attention has been devoted to the electric telegraph and its accessories, we omit purposely further mention of them at present.

Of optical instruments of various kinds, but principally microscopic, Mr. Pillischer, of 88, New Bond-street, exhibits largely, and most successfully. Indeed, every kind of instrument of this nature is to be found in the stand of Mr. Pillischer, in the north-east gallery. A very elegant reading lamp, among other exquisite works of this maker, deserves mention. It appears to be admirably adapted for those whose avocations or whose tastes induce them to write or read by artificial light. Much artistic taste has been displayed in the design of one particular pattern of lamp which came under our notice, and we are informed that this combines economy in action with beauty of appearance. The commonest colza oil need only be used, while the light emitted is of the whitest and steadiest description.

Perhaps a reading lamp may be thought scarcely to fall legitimately under the term philosophical instrument. A good one in all respects is, however, a desideratum in this northern latitude of ours, both to the philosopher and the man of science; and, now that the days shorten and the nights grow proportionately long, the importance of such an apparatus is more and more likely to be appreciated. The high testimony in favour of Mr. Pillischer's reading and microscopic lamp renders further apology for introducing its name into this paper unnecessary, and we commend it heartily to the notice of our readers.

Ross, of 2 and 3, Featherstone-buildings, Holborn, has an excellent show of optical instruments, microscopes, telescopes, photographic lenses, &c., and among them a large compound microscope, with Wenham's binocular arrangement, may be noted as one of the most remarkable. It appears to combine all the recent improvements in this class of instruments, with excellence of workmanship and compactness of form. The distinguishing features of it are a concentric rotating stage, having one inch of motion in rectangular

directions, with rack and very fine-threaded screw movements to the optical part. The clamping it such as to admit of the adjustment of the apparatus to any required angle of inclination, and a secondary stage allows of the holding and adjusting by universal motions all the illuminating and polarizing apparatus below the object under examination. Flat and concave mirrors, diaphragm plate, &c., go to make the appliance in all respects complete. The whole may be neatly packed in a mahogany case when not in use. Many other specimens of compound and simple microscopes are to be seen in Mr. Ross's collection, with separate parts of the instrument detached and in detail. Of telescopes, too, there is an admirable variety, both as regards size and power.

Suffell, of 132, Long-acre, well known in the scientific and mechanical world for the excellence of his mathematical and drawing instruments, and for the general exactitude of his theodolites, displays some of the choicest results of his labours in all these branches, and evidently deserves the fame he has attained for their manufacture. Not less praiseworthy in their way are the rules, scales, levels, &c., for mechanical, scientific, and agricultural purposes shown by James Tree and Co., 22, Charlotte-street, Blackfriars-road. Practical mechanics have long since admitted the care and attention which this firm has devoted to the manufacture of those simple instruments which are hourly required in the processes in which they are engaged, and which enable them to turn out their work with that precision which is so essential in the mechanical arts. It is with pleasure, therefore, that we direct attention to the "exhibits" of Messrs. Tree and Co.

Perhaps one of the most valuable contributions in the way of theodolites to the show of mathematical, philosophical, and scientific instruments in the north-east gallery, is that known as Metford's, but which is manufactured by Pastorelli and Co., 208, Piccadilly, and 4, Cross-street, Hatton-garden. This splendid instrument appears to have had lavished upon it all the ingenuity and niceness of workmanship of which such a contrivance is susceptible. It would absorb far too much of our space to enter minutely into the peculiarities which distinguish Metford's traversing theodilite, but we are certain that railway and ordinary surveyors should only examine it for themselves to be assured of its admirable adaptation to the various kinds of work for which it is intended. No practical point has apparently been overlooked in its construction, and whilst it is of an elaborate character, it is apparently not likely soon to get out of order—and it is moderate in price. The "Improved Level," exhibited by Pastorelli and Co., is not less excellent in its form and fittings. In the way of drawing instruments, barometers, thermometers, and a great variety of appliances to meet the requirements of men of science engaged in whatever branch they may be, the same firm is well represented at the International Exhibition. Bailey, 162, Fenchurch-street, has a considerable display of sextants of different kinds, as well as artificial horizons, prismatic and universal compasses, &c., which all speak in favour of his capabilities for executing such work. Spencer, Browning and Co., of the Minories, in the manufacture of instruments and appliances of a similar character, are not unknown to fame. In fact, they enjoy a long-established celebrity, for their construction of nautical instruments especially, and, as may be imagined, they have succeeded in justifying their claim to that celebrity by their demonstration at South Kensington.

A rather curious collection is that of Braham, of Bristol, in which spectacles of every sort, from the earliest dates to the present time, are to be found, thus showing the improvements effected in those useful articles. The latest inventions in this department of optical science have rather extraordinary names given to them—names which in the pre-scientific age of our great grandfathers and grandmothers would have rather puzzled those venerated individuals to pronounce, or to understand the meaning of if they did succeed in pronouncing them correctly. Take for example, Braham's "pantoscopic, and anti-opthalmioscopic spectacles, spherical eye-preservers, and helical spring eye-glasses." No doubt these are very excellent aids to those who are plagued by weak or defective vision, but we cannot see why simpler titles might not have been given them.

Casartelli, of Market-street, Manchester, cuts a respectable figure in the department of microscopes, telescopes, and mining and surveying instruments, as he does also in regard to steam-engine indicators, vacuum gauges, and steam pressure-gauges. A portable anemometer, invented by J. Dickenson, Esq., government inspector of mines, and manufactured by Casartelli, is an ingeniously contrived instrument for showing the velocity of air current in coal mines, and by means of which may readily be computed the quantity of air, in cubic feet, passing per minute through the air ways. No doubt this instrument might readily be adopted to other purposes than that for which it is especially intended, and at any rate it is as we have said ingeniously designed.

Some admirable and instructively-arranged specimens of glass for optical purposes are deposited in the gallery by Cutts, Sutton and Son, opticians to her Majesty, 43, Division-street, Sheffield. These consist of coloured and white crown glass, plate glass, achromatic flint glass, crown and flint discs used in the construction of the best quality of achromatic object glasses for telescopes, &c. In fact, glasses and pebbles of every quality and kind used in the construction of optical instruments, and in their various stages of progress, from the rough to the finished lense, are here to be seen, and from them a good idea may be formed of the amount of labour exerted in bringing them to the proportion in which they are found in well-made microscopes and telescopes.

In the manufacture of bullion, chemical and assay balances, which is a branch of business connected very closely indeed with philosophical and mathematical instrument making, and constantly requiring the most delicate manipulation, Messrs. Ladd and Oertling, of 192, Bishopsgate-street Without, are honourably known. In the Exhibition several specimens of their workmanship are shown. The peculiarity of their balances, and which has been pirated by some unscrupulous scale-makers without acknowledgment, is that they are all, whether large or small, constructed on the principle of three edges working against three planes. Not only does the fulcrum rest upon a plane, but the pans also are suspended by inverted planes upon knife edges affixed to the ends of the beam. The advantages gained by this system are twofold; first, it admits of the balance being adjusted to the greatest point of sensibility without diminishing its precision and constancy, and, secondly, when the balance is not in actual use the pans rest upon supports entirely independent of the beam.

These balances are used extensively at Her Majesty's Exchequer, at the Royal Mint, at the Bank of England, and other public establishments, and in all, we have reason to know, are highly approved.

The instruments exhibited by Negretti and Zambra, of Cornhill, Hatton-garden, and Regent-street, embrace specimens of almost all the varieties which have been enumerated in this notice, and certainly if the public be not aware of the excellence of most of them, it is not the fault of the public press. The publicity already given to the works of this firm, indeed, renders it unnecessary for us to expatiate further upon them.

An indicator for solving nautical and astronomical problems occurring in navigation, with sufficient accuracy for nautical purposes, is an ingenious contrivance exhibited by Charles Moore, Quay-parade, Swansea. The deviation of the compass by local attraction is also discoverable by its aid, and we are told that its action is not influenced by climate.

Immeasurable indeed are the beautiful and highly useful inventions exhibited in class XIII., they are the tangible reflex, so to speak, of the glorious brain and hand-labour of the philosophical and mathematical instrument makers of the United Kingdom, and they are also of a character to demonstrate to the world the perfection we have attained in this branch of art, and the superiority we mean in the future to maintain. We leave this department of the Exhibition now, not because we are inclined to do so, but because inexorable "space" says we *must*.

THE IRON MANUFACTURE OF GREAT BRITAIN.*

(Continued from page 189.)

It will be remembered that in our former paper upon the above subject we were compelled to come to a somewhat abrupt conclusion at the very point where its consideration became especially instructive and important. Gladly, therefore, is the opportunity taken of pursuing the iron manufacture of Great Britain, as exemplified in the work of Messrs. Truran, Phillips, and Dorman. The quality and quantity of metal produced are, after all, the vital points upon which depend everything that is connected with the iron trade of this country. The authors of the book under notice appear to have been acutely sensible of this fact, and a very considerable portion of it is devoted accordingly to the "produce and "quality of metal." They give statistics of the rate of production at many of the most considerable works throughout the kingdom, and deduce therefrom practical rules which may serve for the guidance of those who are endeavouring to arrive at the highest state of efficiency in the management of their own. It is stated in the volume on iron manufacture that "the foundry iron furnace at the Dowlais "works is of 275 cubic yards capacity, and is "blown with a blast of 5,390 cubic feet of air "per minute. The materials charged at the "top, in addition to fuel, consist of calcined "argillaceous ore, coal, and limestone. The "yield, or consumption, averages 48 cwts. of "calcined ore, 50 cwts. of coal, and 17 cwts. "of broken limestone for every 20 cwt. of "crude iron obtained. The weekly make of "iron is occasionally over 130 tons, but we "may assume this as sufficiently high for our "calculations. The produce of cinder weekly "amounts to nearly 250 tons. The weekly "consumption of solid material at top will be

* Sketch of the Mode of Manufacturing Gunpowder at the Ishapore Mills, in Bengal, with a record of the Experiments carried on to ascertain the value of charge, windage, vent and weight, &c., in mortars and muskets; also Reports on the various Proofs of Powder, by Colonel William Anderson, C.B., late Agent at Ishapore, with Notes and Additions by Lieutenant-Colonel Parlby, Retired Bengal Artillery. Weale. London: 1862.

"as follows:—calcined ore 312 tons, coal 325 "tons, limestone 110 tons 10 cwt., total 747 "tons 10 cwt. By measurement, these ma- "terials in a mass would occupy 1,066 cubic "yards.

"The air delivered by the tuyeres weekly "weighs 1,695 tons, and measures 50,550,400 "cubic feet. From these quantities we "obtain the following ratios, which are the "extreme proportions when the iron is of a "grey quality, and smelted from argillaceous "ores. The weekly consumption of material "at top is at the rate of 54 cwt. per cubic "yard capacity. The weekly produce of "liquid matter from the hearth is nearly 28 "cwt. per cubic yard capacity.

"The produce of metal from the hearth is "at the rate of 9·5 cwt. weekly for each yard "capacity.

"Each ton of coal charged into the furnaces "suffices for the production of 23·4 cwt. of "liquid matter in the hearth. Estimated on "the carbon in the coal, the ton of iron is "produced with a consumption of 43·5 cwt. "of carbon, and the ton of liquid matter— "iron and cinder—deposited in the hearth "with a consumption of 17·1 cwt. of carbon. "The solid materials introduced into the fur- "nace weekly measure in their original form "1,166 cubic yards, the liquid matter obtained "measures 172 cubic yards. The solid ma- "terials charged at the top are in the furnace "40 hours before being reduced to a liquid "state. The solid materials descend through "the throat at the rate of 28 inches per hour, "at the top of the boshes the descent is "reduced to 7 inches per hour, but is accelera- "ted at the hearth to 35 inches per hour; "The consumption of blast per minute is at "the rate of 20 cubic feet of air to each yard "capacity of the furnace.

"The ton of iron is produced with a con- "sumption of 3,888,490 cubic feet of air. The "air decomposed in smelting one ton of iron "weighs 13 tons. The weight of the air in- "troduced through the tuyere is to the weight "of the solid materials introduced at the top "as 16 to 7.

"The materials, solid and gaseous, charged "into the furnace for each ton of iron smelted "weigh 18·8 tons. The weekly consumption of "solid and gaseous materials weigh altogether "2,442 tons, of which 380 tons are obtained in a "liquid form at the hearth, the remaining "2,062 tons escaping in the gaseous form at the "top. Hence for each ton of liquid matter "obtained 129 cwts. of gases are evolved from "the furnace.

"The atmospheric air introduced weekly "measures 1,872,223 yards; the gas evolved "from the tunnel-head measures 7,488,000 "cubic yards. The ascending gases traverse "the furnace at its largest diameter at the "rate of 415 feet per minute, increased at the "throat to the rate of 1,660 feet."

Such are the particulars of the great works at Dowlais, and we have thought fit to transcribe them *in extenso* for the satisfaction of those of our readers who may not happen to meet with the volume from which they are extracted. In relation to Dowlais, we are furnished with minute statistical information as to other and inferior kinds of iron—the rate of production, expenditure of materials, &c.—but into them we need not at present go. The celebrated Hirwain foundry is also referred to, and many valuable facts in connexion with it are given. Economy is the great object sought in almost all the works of the kingdom, and it is to be feared that this is sometimes effected at the expense of the quality of the metal produced. In no operation connected with iron-works has there been a greater reduction made in the consumption of materials than in the consumption of coals. In several Welsh works an actual saving of two-thirds the quantity at one time used has been accomplished, and this without deterioration of metal. In 1791 the consumption of coal to each ton of pig iron averaged 6 tons, in 1821 it had been diminished to 4 tons, and in 1831 2 tons and a quarter were found sufficient, and this indeed is about the proportion now employed. It would be simply impossible for us to follow closely the track of the authors of "Iron Manufacture" in their elaborate and exhaustive researches. Nothing that is of interest with respect to the mode of dealing with the materials used in the production of iron appears to have escaped their penetrative explorations, and their work is consequently laden with the rich spoils resulting from their labours.

In connection with the blast furnace, some curious and, at the same time, instructive information is given, as for example, this, "the "make of the blast furnace varies with the "season of the year. * * * It is well "known to smelters that with materials of "similar quality, and volume of blast un- "altered, the make of the furnace is greater "in the winter months than at any other "season. Until within the last few years "this was attributed to the coldness of the "air; and on the introduction of the invention "of hot blast to the manufacturers of iron, "this superiority of cold winter over warm "summer air was adduced as a reason against "using the hot blast. The greater efficiency "of cold air was considered by some writers "to arise from its increased density, which "augments, in proportion to the decrease "of temperature, a given quantity of air "containing more oxygen in winter than in "summer. The cause of this superior make "in winter is now, however, ascribed to what, "no doubt, is its true cause—the greater dry- "ness of the atmosphere in winter as com- "pared with summer."

In the seventh section of the book under review the question of the "density of blast" is discussed with much acumen and practical ability; and the abandonment of certain fallacious theories which, for a considerable time, obtained belief is commented upon. It is a fact known, we believe, that up to this hour considerable difference of opinion exists, both as to the proper density of blast necessary to produce the best effect, and as to the most efficient way of applying it. As to the latter question, the most common mode of admission for the blast is by three tuyeres, one on each side and the third at the back. Some iron-masters have, however, we are told, adopted the plan of distributing the blast, as it were, by admitting through ten or twelve apertures or nozzles.

The advantages supposed to attend the use of a large number of small pipes are—a more perfect combustion of the fuel, and, consequently, economy of blast and smelting materials, and an increased make of iron. The authors of the work under review are, on the contrary, of opinion, and that after repeated testings and experiments, that these advantages are illusory. "If the blast," they say, "be "cut up into a number of small jets, their in- "tensity and ability to penetrate the mate- "rials are inferior to those of larger jets." Arguments in favour of this view are adduced, and we think those arguments conclusive.

The form of the interior of furnaces has been much discussed, and it varies at several works. In the book before us a number of illustrations are given of the different kinds of furnaces in use, and the whole question is considered with that scientific and practical exactness which is characteristic of its authors. Those who are anxious to learn more of this part of the subject must, however, be referred to the pages of "Iron Manufacture."

In the ninth section the quality of the crude iron as affected by the structure and composition of the ores is treated of, and it must be allowed that it forms a momentous consideration to iron smelters. On this point we are told that "the quality of the iron as estimated "by the quantity of carbon in combination, is "directly dependent on the structural arrange- "ment of the ore, and that the fusibility is de- "pendent on the same causes, also varying "with the per-centage of associated carbon." This theory will clash with the notions of some who hold that the character of the fuel used has very much to do with the quality of the iron produced. We conceive, nevertheless, that the views propounded by Messrs. Truran, Phillips, and Dorman are in the main correct, and that fuel plays a secondary part only in the process referred to, so far as quality is concerned. Advancing now to the deeply-interesting question of the "hot blast," our authors at once assert that the effects of its introduction into the manufacture of iron has been "much exaggerated." "The saving "in fuel by the application of the hot blast, "and the increase of make due to it, are not "in general one-fourth of what has been at- "tributed to it." Contrasts are instituted between those works where the cold blast is still adhered to, in support of this rather startling statement, and it must be admitted, in presence of the facts adduced, that there are strong grounds on which to sustain it. The employment of furnace gases, which has occupied the attention of many able men during the last few years, has a chapter devoted to it in the work under notice. The general conclusion come to thereon is that the scheme is not likely to be attended with anything like decided success, but that, on the other hand, much time and money may be wasted in fruitless attempts to realize it. "By "calculations founded on very insufficient "data, the heat capable of being attained by "the combustion of gaseous products has been "greatly over-estimated, and in practice the "maximum working temperature scarcely "reaches a third of the theoretical state- "ment."

The use of heated air and its effects are dwelt upon at much length, and with a great deal of calm argumentation. It is not possible for us to follow the writers through their very lucid and temperately-expressed theories on this part of their subject, but we can promise those who revert to the book itself for information thereon, that they will have no cause to regret doing so. A section devoted to the employment of raw coal in blast furnaces, brings us to that which relates to blowing engines. In respect to these our authors express some very decided and practical convictions, and as those convictions are likely to be of great interest to many of our readers, it is desirable to summarize them here. There are, it is stated, in this country about three hundred and ten blowing engines. "These we have personally examined, and "consider their make and power, and the "expense of their maintenance, inconsistent "with the present advanced state of mechanical "engineering. A deficiency of power is a "defect almost universal. When it is con- "sidered that the entire process of the opera- "tions, as regards quality, produce, and "economy, is dependent on the blast, the "necessity of having superior blowing engines "of ample power, and maintaining them in

"first-rate working order, is apparent. But, "as ironmasters are not usually practical engi- "neers, most of the faults observed in their "engines must be placed to the credit of their "makers. . . . A blowing engine should "be able to work a month without stopping, "and then require not more than an hour's "delay. No really efficient engine should "need to stop more than thirty hours in a "year for current repairs." No doubt the conditions here laid down are remarkably stringent, but with those who have stipulated for them, we believe, they are capable of fulfilment. The introduction of the high pressure principle has undoubtedly been attended with much advantage; but evidently much more remains to be accomplished in perfecting and economizing the action of the blowing engine.

The refining process now so commonly resorted to in the Welsh iron works, is elaborately treated of, as are those of boiling and puddling. The use of hammers and squeezers, too, are lengthily described; and the chapter on Rolling Bar Iron is so interesting and important that it ought to be transcribed entire. That, however, is clearly impossible, and we can only promise that at some future time we will probably give copious extracts from it, as well as from the chapter on Rolling Plates, which is not less worthy of quotation.

In the 21st and last section of "Iron Manufactures of Great Britain," and under the general heading of "Sundry Notes on Iron-making," we find a fund of useful and practical information on minor points connected with the art, and which go to make the book a complete and exhaustive treatise thereon.

It is with feelings of intense satisfaction and confidence that we recommend this work to the vast and intelligent community to whom it is addressed, and we should be wanting in our duty if we closed this notice of it without making an earnest appeal to the committees of every Mechanics' Institution, and Scientific Society in the United Kingdom to place a copies of it in the libraries attached to their meeting places. The price of the book—necessarily high—places it beyond the reach of the individual workman; but by some means or other it should reach his hands. We are certain, indeed, that the heads of engineering and mechanical establishments would find it advantageous to purchase copies for free circulation among their employés. The valuable information thus distributed would make those employés far more serviceable to their masters, and at the same time bring their knowledge of the material, with which they so largely deal, up to the requirements of this essentially and almost literally iron age.

THE SEWER AND WATER SUPPLY OF PARIS.

The twenty-third volume of the "Journal of the Royal Agricultural Society of England," just published, contains the following interesting article by P. H. Frere, upon the present state of the sewers and water supply of Paris:—

England may well look with interest to the changes made or contemplated in France for the disposal of that town-refuse which is a possible source of wealth, but, if ill dealt with, a certain cause of annoyance; and indirectly its agriculture is concerned in the result. With us, to a certain extent, the die is cast; the contents of the closet have penetrated, with the kitchen refuse, &c., into the common sewer, into which they are washed by an unrestricted supply of water. To set up a wall of separation—to limit the amount of dilution—would in themselves be steps of extreme difficulty, because in one sense retrograde. Paris, on the other hand, is still, in the main, uncompromised. That city is in a state of transition; generally, the old-fashioned pit still exists, for the most part unsupplied with water; but a large water-supply has been procured for houses of the better sort. But even then the soil-pit still remains wholly or partially separated from the common sewer, and the question still is to be decided whether this separation, whole or partial, shall be maintained; and consequently whether the night-soil of Paris shall retain, as heretofore, all its solid and liquid constituents, or only the former; and again, to what extent these fertilisers shall henceforth be diluted.

After the great works undertaken to procure a water-supply from the Seine, from the Canal de l'Ourcq, and from the great Artesian well, every householder who is willing to pay the rate can have a supply of water for water-closets as well as other uses. The water company, however, endeavours to regulate and limit the supply contracted for, by making only such an aperture as will allow the amount paid for to pass in a continuous stream into an inner cistern in twenty-four hours. The following is the estimated rate of consumption:—

	Litres.	Gallons.
For a man	30	6 1-10
" carriage	75	16 1-2
" horse or cow, &c.	100	22
" water-closet	75	16, 1-2
" garden or court, per square metre (10 1-2 feet)	5	1 1-10

A contract may be entered into for 500, 1,000, 1,500, &c., litres per day, for an annual payment of 60 fr. for Seine water, or 50 fr. for Ourcq water, per 500 litres (110 gallons). The use of the water-closet is then inaugurated; how is it henceforth to be regulated?

The builder who contemplates making a house must communicate to the Board his plan of operation; the choice open to him will depend on the locality. The new Boulevard de Sebastopol, with its costly and magnificent system of sewers, is the type of the new regulations. If the house be in that quarter, a separate pit must be provided for the soil; but it will be so connected with the main sewer that the nightman will have access to it therefrom, and without entering or disturbing the dwelling, will first deoderize, and then let off the fluid into the sewer, and afterwards convey away the solid "soil" through a passage in this new subterranean town to the cart and to the reservoir. Otherwise, by another plan under consideration, the soil, &c., would drop into a cylindrical cistern, divided vertically by a perforated metal screen or sieve, through which the fluid percolates of itself into the sewer. In either of these cases the fluid elements are lost, and if these contain the higher per-centage of nitrogen, the loss may be much more than *pro rata*.

It remains to be seen whether, since this magnificent network of drains has been already organized to retain the fluid as well as solid excrement, and other means have been provided for dealing with the soil, it will pay by enlarging the pits, emptying them more often, and restricting the supply of water used in the closet. One important step has been taken towards this end. A tank fitted to a railway truck, containing 6 to 10 tons, has been made and exhibited in our International Exhibition, which will be conveyed for 60 miles on the Eastern Railroad at a charge of 2s. for 6 tons. The present "night-soil," when delivered in "hungry" champagne, is valued at 8s. per ton. If then the "soil" retain anything like its old strength, its value to the farmer will leave a large margin to pay for its transport along the subterranean street to a reservoir at the railway terminus. But if there be a great dilution, and many small sources of supply have to be visited and tapped in succession, the costs of removal will roll up, until this "gold may be bought too dear."

At all events, these philanthrophists and philosophers who long to see the circle of reproduction completed by the restoration to the field of all the human fæces which contaminate our great cities, must cast a curious and anxious eye to the magnificent new French suburb, where, if anywhere, their views may be economically realized, because a solid foundation has been laid, and there are means and appliances for the distribution which only wait for one or two connecting links. In other quarters of the town, practical improvements have been introduced, by which the carts are filled at night by means of a joint and hose fastened to an opening in the pit, so that it is emptied from the street by suction. The loaded cart then proceeds to the *depotoir*, or sink, from which the deposits are propelled by a steam-pump through a tunnel seven miles long to an opening cut in the Forest of Bondy. Here they are either desiccated and made into *poudrette*, or shipped by barge-loads along the Canal de l'Ourcq to Vaujours and elsewhere.

The Water Supply of Paris.

For centuries the supply of water for Paris has occupied the attention of the French Government. Philip Augustus erected the first fountains; his successors and the municipality organized in the squares and open supplies of water drawn from the northern springs. Marie de Medicis, restoring a Roman aqueduct, led in the waters of Arcueil. In the reign of Louis XIV., pumps were placed by the bridges of Notre Dame and the Pont Neuf, to raise the water of the Seine. A century later similar works were set up at Chaillot. But they all turned their backs on drains, and sewers and their contents, leaving the sun, the rain, and the river to settle those matters.

Water which had served domestic purposes ran in streams down the streets in mid-channel, and either joined the Seine on the south, or on the north the ditch of Ménilmontant. This ditch, when its exhalations began to threaten the health of the neighbourhood, was paved and vaulted, and converted into the main sewer which encircled the town. The outscourings were allowed to run into pits in the open fields; and the night soil collected in the pits underneath the houses was taken away by night, to be thrown, first into the charnel-house of Montfaucon pell-mell with the bones of criminals, and afterwards into the empty plaster-pits of Buttes Chaumont. Such was the system which survived to our own times. We may add, that from the sixteenth century the gardeners who cultivated the marshes of the Temple, applied to their land the sweepings and straw manure of the town; and when Paris, spreading daily, ejected them from within its bounds, by means of this same manure, they converted the plain of Vertus into a garden of inexhaustible fertility. Beidel, too, about 1,780, formed the idea of solidifying, by drying, the thick liquid in the basins of Montfaucon, and manufacturing *poudrette*, by which the first company of adventurers was enabled to pay a rent of £22,000, and reap a handsome profit.

The sanitary reform of Paris dates from 1830. The completion of the Canal de l'Ourcq, which delivers 100,000 tons of water, at a level of 27 yards above the Seine, altered the whole state of the town. The principal was adopted that a group of houses constituted a block (*ilot*), to be scoured by a stream of running water, and provided with a water-post (*borne fontaine*) on a high level, and a sewer's mouth below. An end was thus put to the torrents of filth which had hitherto deluged the streets. These were re-laid in a convex form, skirted by foot pavements; and under all the main thoroughfares waterpipes and drains were laid. The management of the night-soil underwent a like change. M. Mary was so adventurous as to propose to construct a syphon 7½ miles in length, terminating in the reservoir of Bondy, for the purpose of emptying the pestilential pools of Montfaucon. This scheme was unprecedented, and apprehensions were entertained that the pipes would become choked by the pasty matter. After five years' opposition he gained his point, and the construction of the "dépotoir" was the result. This work consists of an assemblage of cisterns, into which the produce of each night's carting is emptied. The contents are then forced by a steam-pump through an iron pipe to a clearing of seventy-five acres made in the middle of the Forest of Bondy, well out of reach of Paris and its atmosphere. M. Mary calculated that this pipe, which traversed the market gardens of Noisy, might furnish liquid manure, to be sold at a cheap rate at convenient stations. But the practice of buying town-sweepings and stable manure was so established that, until 1850, night-soil was overlooked; nor was any attempt made to introduce its use in the environs, prior to the experiments which led to the establishment of the farm of Vaujours.

About 1850 the introduction of railroads gave a new impulse to the improvements of Paris. Traffic of all sorts was increased tenfold, and, as a consequence, streets required to be widened, and the whole town, as it were, re-organized. Then it was that Government came forward and sketched the plan, which is realized in the magnificent city such as it now stands.

Two great lines now intersect one another at right angles, so as to form a cross—an idea of the time of Philip Augustus; the one, the Rue de Rivoli, runs parallel to the river; the other, the Boulevard de Sebastopol, comes sloping down from the hills on the north, and again rises to the south. On the latter line sanitary arrangements have been comprehensively planned and carried out. We find

a complete subterranean town, provided with vaulted thoroughfares 35 yards wide, macadamised or paved, which contain sewers showing a section *(profil)* of 3, 4, or 6 yards, with polished sides and serviceable foot-pavements, in which, through an inner channel, the stream of sewage-water flows, fed at the corner of each street by lesser sewers, themselves drawing their supplies from the drains which abut on every house. This is such a scheme as the English *Board of Health* suggested, but with this difference, that instead of a system of small pipes, provision is here made on a large scale for all the requirements of town life, including water and gas. Besides the rain-water and that which has been used for domestic purposes, the drainings from the closets run down these channels, the solid portion of the deposit being retained in the pits by the filter. There is no connection with the outer world. The system is self-contained; water and gravitation are the sole agents employed.

The drains connected with the private houses are oval sewers, 4 feet 2 inches by 7 feet 6 inches, in which the workman passes easily to and fro with his barrow. The main drains, constructed under the great lines of traffic parallel with the river, are circular tunnels of 10 feet in diameter, containing a railway with a 3-feet 11-inch gauge, and a channel for the waters between the lines of rail. Lastly, the main sewer, which forms a chord to the windings of the Seine, between the Pont de la Concorde and the Pont d'Asnières, is an elliptic tunnel, having a horizontal diameter of 20 feet, in which is contained a canal 11 feet 8 inches wide, traversed by a barge, with a footpath on either side 3 feet wide. All these works are executed in cement, so that the smooth and polished walls and their softened outlines reflect the light, transmit sound, and give free passage to the waters, which leave no taint behind. From the dwellings they received grease, the refuse from the kitchen, and the household water *(eaux menageres)*, as well as the disinfected liquids drawn from the pits of the closets. The paved streets transmitted their mud, and the macadamised boulevards their scrapings. Markets, slaughter-houses, barracks, paid their tribute of manure—vegetable refuse, blood, urine, or undiluted night-soil. This confused mass, mixed with water, issued from the sewer's mouth at Asnières in a thick and dark stream, flowing at the rate of 1 ton per second.

To provide against the accumulation of a great mass of filth near the sewer's mouth, the following ingenious device was adopted :—

The centre of the main drain is occupied by a canal 2¼ miles long, having a fall of 1 in 2,000. On this canal a barge is employed, from the fore part of which is suspended a metal flood-gate *(vanne)*, which fits exactly to the sides of the tunnel up to a certain water-level, and lowered by leverage to within a few inches of the bottom. By these means the stream is headed up behind the floodgate, which as soon as there is a head of two feet of water, forces out through the small aperture left below a perfect torrent of refuse, sand, and even stones, which are mashed and rolled together, and thrust onwards in a long drift 100 yards in advance.

As the barge itself is propelled slowly forwards by the stream which it holds in check, the torrent keeps advancing, and the outscourings never find a resting-place till, at the end of ten days, the mouth of the sewer is reached. The boat then performs its backward journey by the aid of floodgates lowered from the roof. These, acting like locks on a canal, raise the water to an artificial level for a distance of 11,000 yards at a time, by which means the barge is gradually floated back.

The lighting and signals had still to be provided for. At first small lamps, such as are fixed to railway trains were tried, but their light was found to be too dazzling to those in front, whilst it left those in the rear in deep shade. A common oil-lamp in a glass globe, distributing its light equally around to a distance of ten yards, was ultimately preferred. Red, blue, and green railway lanterns answer perfectly for signals.

Thus far provision had been made for cleansing the town, but at the cost of the Seine, where a pestilential delta would be formed at the sewer's mouth. The great point was to extract all solid matter from the stream without interrupting its flow; this alone would lodge and accumulate; this would interfere with working pumps for irrigation; liquids would float away with the stream, and would undergo slow combustion when in contact with the air, and vanish.

The various solid bodies contained in the stream, though blended together by the flood, would not really mix or amalgamate. Their specific gravity would determine their position; the grease would float, the sand sink rapidly, straw and organic matter would be found in various degrees of suspension. They must all be disposed of.

The grease is, in great measure, collected as a scum behind the barge, where it is skimmed off and employed in making black soap.

The first attempts at "straining" the stream were unsuccessful. The straw manure required a special device.

A simple bar became blocked with a tangled mass of straw and dung. A barrier of plate-iron pierced with holes, made to fit the aperture exactly, and therefore 8 ft. 8 in. wide, which was fixed in a sloping direction, hardly arrested any of the floating substances. The openings were bunged up, and the straw, &c., glided up the inclined plane and topped the fall.

The last device was to make a wooden grating, with bars placed lengthways, three-quarters of an inch wide and three-quarters of an inch apart, inclined in the direction of the stream's flow. The length of the incline was 26 feet, which gave a slope of 1 in 5. The workmen, armed with rakes, who combed and scraped the gratings, collected as much as five or six tons of rubbish per day.

Whilst the work was still experimental the sewer supplied in four months 500 tons, which was not only so much infectious matter got rid of, but manure placed at the service of agriculture.

The nursery gardens of the Bois de Boulogne were not slow in adopting its use, and found its action very rapid—as the gardeners say, if you expose it for twenty-four hours to the air it takes fire. With alternate layers of clay or marl it forms an excellent dressing.

To return to our subject. The collecting the sand which moves along the bottom of the sewer was a very simple matter. Only make a barrier, and a bank will soon be formed against it, which the steam-drag, such as is worked in the Seine, will readily remove. Even these sands may be serviceable to agriculture; they are fine, and blackened with organic matter like peat, and may therefore prove a useful dressing to chalk and clay lands.

Accumulations of gas remained to be dealt with. Where there is sewage-water, it is always accompanied by a discharge of carbonated hydrogen gas, which rises to the surface in numerous little bubbles. As the sewer has been so planned as to have a fall of about 13 inches where it joins the Seine, the water, when broken in the fall, parts with a portion of the gas contained in it. To take advantage of this, a cowl has been built over the cascade, which is surmounted by a fire of glowing coke; the blue flame of the carbonated hydrogen is easily recognized at the top of the vent, where it mounts and undergoes combustion, instead of bubbling up in the fleeting current.

To sum up these details; the foul stream which enters the sewer of Asnières, to be turned into the Seine at the lowest possible point, first encounters the barge with its movable flood-gate. Finding no escape but by the aperture near the bottom, it is converted into a scouring torrent, which whirls along all the deposits for a distance of two and a half miles. A sort of floating island of scum is formed round the boat, from which the grease is collected for industrial purposes. At the mouth of the Seine the stream next encounters a long grating, suspended in mid-channel but disconnected with the bottom that the sand may pass freely. There it parts with all its floating substances, such as straw, vegetables, or wood, which form a bed *(paillasse)* on the inclined plane, from whence they are removed by drag-rakes.

Still farther on a bar is so placed as to form a fall of 13 inches; the sand is thus arrested, and the bank which it forms is continuously removed by the scoops of the steam-drag. The hood, with its fire of coke, placed over the fall, attracts and consumes the noxious gases.

The solid and gaseous bodies being thus disposed of, nothing remains but the fluid, which contains matter in chemical solution, and this may properly be turned into the Seine, because its purification will soon be accomplished by slow combustion under the influence of the atmosphere; the dark stain caused by its admixture will soon be obliterated, and before reaching Passy the river will have regained all its purity.

These statements have been chiefly derived from two reports by M. Mille, published in the Appendix to the "Annales de Vaujours." For further explanations I am much indebted to the excellent models of sewers exhibited, among many others, in the French Department of the International Exhibition, as well as to the courtesy and patience with which the gentlemen in charge of these models have answered my inquiries.

When examining these models I at the same time saw with interest the pipes manufactured by M. Hermann et Compagnie, contractors for the Paris waterworks. These pipes are perfectly smooth within and without, and uniform from one end to another, without any kind of projection. When a joint is to be formed, a band of india-rubber is slipped over the ends of two pipes placed in juxtaposition. Over this band two iron rings, slightly conical in form, lying ready to hand on either pipe, are driven home till they almost meet. By this simple but effectual kind of joint, the use of solder and of skilled labour is dispensed with, the re-adjustment of one or two lengths much facilitated, whilst it is found in practice that for any given bore, required for any purpose, one-fifth less iron may be employed than has been usual. The pipes of all sizes now laid down for the Paris Waterworks are thus united.

VENTILATION OF SHIPS.

A new ventilating apparatus has been erected on board her Majesty's ship "St. Vincent," by Mr. Wilson Phipson, C.E., of London, the results of which are satisfactory. Mr. Phipson has obtained from the Government an order to ventilate the lower deck of her Majesty's ship "St. Vincent" as a trial experiment. It was thought that a trial with a deck 190 feet long and only 7 feet high, in which 450 persons are swung up to sleep every night, would constitute as severe a test as was possible to be found. In the hands of Mr. Phipson it has, however, proved a complete success. The whole of the air of that 190 feet deck is renewed every 15 minutes without the least perceptible draught; and where before the atmosphere was almost stifling, now not the slightest odour is perceptible, and the men and boys enjoy a healthy night's rest. In the company of Captain Marcus Lowther, the commander, Dr. Cunningham, surgeon, Dr. Phipson, F.C.S., and several others, Mr. Wilson Phipson proceeded to explain his apparatus, and to make experiments by filling the deck with smoke, to point out the manner in which the air was renewed and the time required for its renewal. The fresh air enters by an artificial patent winsail, containing a ventilator, which is connected with a two-horse power steam engine. The things are so arranged that with 40, 50, 60, or 80 strokes of the piston per minute, 4, 5, 6, or 800,000 cubic feet of pure air are supplied per hour. The supply given depends upon the number of individuals, each person requiring a certain amount of air per minute, and the apparatus is so disposed that an amount a little greater than can ever be required is furnished by the machine without any perceptible draught. The air, it appears, enters the deck in cyclones which are bipolar, or composed of two curves, a curve of maximum and a curve of minimum velocity. The quantity supplied is indicated at any moment by the needle of a dynamometer connected with the ventilator. The expense of this ventilation, supposing 700 men on board, is, as near as we have been able to calculate, about seven-tenths of a farthing per man per night.

STEAMBOATS LIGHTED WITH GAS.

"The Wallasey Commissioners," says a Liverpool paper, "who have taken the lead in introducing the most perfect construction of ferry-boats that ever floated on the waters of the Mersey, seem determined to maintain their supremacy by availing themselves of every improvement in navigating the river which art or science can suggest. Their splendid new boat the "Water Lily," built by Messrs. George Forrester and Co., and Messrs. Jones, Quiggin and Co., is now lighted by gas throughout. Instead of the dull, lurid flame produced by oil, the signal lamps are brilliantly illuminated by a jet of the clearest gas-light. At night the engine-room is now quite light, every part of the machinery, in fact, being more clearly visible to the engineer than during the day-time. A couple of sun-burners at once give light and ventilation to the passengers in the saloons, rendering these places more like ele-

gant drawing-rooms than the cabins of a steamer. Mr. Highfield, the skilful manager of the Wallasey Gas-works, has most successfully accomplished his purpose, and we congratulate him on being the pioneer in applying his genius to bring out an invention that must add so materially to the comfort and safety of those persons who are compelled to cross the river by night. It does not require more than fifteen minutes to charge the receiver with sufficient gas for a night's supply. The apparatus is constructed to prevent all possibility of an explosion, and is ot in any way affected by the motion of the boats. The cost of illumination will be at least 50 p r cent. less than that of oil. The light only requi es to be seen in order that its superiority may e appreciated; and as in a small vessel the rece er is capable of containing a supply for three nights' consumption, we may expect in a short time to have our steamers as they cross the Atlantic brilliantly lighted with gas. Truly this is an age of progress."

WARNE AND CO.'S CONSOLIDATED EMERY WHEELS.

ON Wednesday last a trial of Warne and Co.'s newly-patented emery wheels, took place in the Western Annexe. These wheels are intended as a substitute for and an improvement on the ordinary leather emery wheel—used for polishing iron work—more especially case-hardened work. We saw on Wednesday last two kinds of wheels experimented on, one of which was a small desk composed of vulcanized india-rubber and emery, and the other was composed of oxydized oil and emery. The latter was superior and, we were given to understand, cheaper than the former. Oxydized oil, a newly-invented substance, bids fair to become of considerable value. In the present instance there can be no doubt of its utility. We are informed that wheels composed of vulcanite and emery are equally effective for cutting, grinding, and polishing iron or steel of any description. They are mounted on spindles in the same manner as grindstones or other grinding wheels.

SIR CHARLES BRIGHT'S IMPROVEMENTS IN ELECTRIC TELEGRAPHS.

(*See page* 231.)

SIR CHARLES T. BRIGHT, formerly engineer to the Atlantic Telegraph Company, has just patented further improvements in telegraphs, a portion of which we can only find room for in this journal.

"In the first part of my invention," he says, "which has reference to the receiving apparatus or relay, I employ conducting fluids in a state of motion, into which the movable part of the relay is inserted or removed, in order to make or break local or secondary circuits, so that the conducting surface with which contact is made or broken is constantly changed; and I prefer for this purpose a fine stream or fountain of mercury, or acid and water, but I do not confine myself to these fluids, as any other suitable conducting fluid may be used.

At fig. 1 is shown a relay, with a reservoir for holding the mercury or conducting fluid in which A A^1 are a pair of coils of fine wire; *b* is the axle of a magnetic needle contained within and actuated by the coils; the axle *b* has fixed to it an arm *c*, which is stopped on each side by two adjusting screws in the usual manner, one of which is shown at *d*. The ends of the coils are led to terminals *e e*, which are connected to the line wire and to the earth. The reservoirs F F^1 are fixed to a tube *g g*, fitting closely round the arm or bracket *h*. The necks of the reservoirs are hollow, and their orifices *i i* are opposite to two passages in the arm *h* (shown by dotted lines), when the reservoirs are in a vertical position; *k* is a pipe fixed to the arm *h*, communicating by the dotted passage with the upper reservoir through which the stream of mercury or conducting fluid flows to a receiver *l*, and thence through the lower passage, marked also by dotted lines, to the lower reservoir. When the upper reservoir is empty, the position of the two reservoirs may be changed by the crank handle *m*, which carries a pinion *n* gearing into a wheel *o*, which is fixed to the end of the tube *g g*. The upright P, which supports the bracket *h h* and the reservoirs F F^1, is connected to the terminal *q*. The upright R, which supports the coils A A^1, and carries the axle *b* of the magnet within the coil, is connected to the terminal *s*. The local or secondary circuit being connected to the terminals *q s*, on a current being sent through the coils A A^1, the arm *c* comes in contact with the fine conducting stream flowing from the pipe *k* to the receiver *l*, and thus completes the local circuit.

"By this means perfect contact may be made with the most delicate horizontal needle, and the power required to work long circuits is much reduced; signals may be recorded by the arm resting in the stream of fluid or by passing through it. If signals be required on each side of the relay the arm may terminate in a fork and may be suspended, together with a magnetic needle, by a fine thread of silk, the axle being prolonged below and dipping in a cup of mercury so as to be in connection through the upright R with terminals *s*.

"I also employ a series of streams or fountains of conducting fluid, the motion of the movable part or parts of the receiving apparatus among them causing various degrees of motion of such movable part or parts to be marked upon any suitable recording apparatus included in the local circuit, by which various deflections, and the time in which such deflections rise and fall, may be recorded on paper.

In the second part of my invention, which has reference to registering or recording the effects of electrical currents, I employ a band of paper, drawn on by a train of clockwork or any other convenient motive power, and I cause a colouring fluid or fluids in a state of motion to impinge upon the paper and mark a line or a series of lines thereon; the line or series of lines is broken from time to time through the colouring fluid being intercepted by an arm or arms moved by the electric currents, and thus the duration of the currents or their variation of force may be directly recorded upon paper; and for registering the effects of earth currents I employ the clockwork train, carefully regulated as regards its speed of motion, so that the time of any deflection may be noted upon the paper.

Fig. 2 represents the key adapted for regulating the ordinary single current alphabet of dots and dashes. *a a* is a lever key working upon an axle *b*, and operated by the pressure of the finger upon the ivory button *c*. The key and the base *d d* upon which it is fixed are connected with the terminal *e* by the metallic strap *f*, and the terminal *e* is connected to the line wire when the instrument is in use. The stud *g*, which stops the motion of the key, is connected to the terminal *h*, which is connected to one pole of the battery, the other pole of the battery is connected to earth so that a current flows into the line when the key is depressed. At the short end of the key is a screw *i*, the lower end of which presses against a small arm or lever *k*, and thus prevents it from coming in contact with the screw *l*, against which it would otherwise be pressed by the spring *m*. A click *n* attached to the arm *k* takes hold of the rough surface of a wheel *o*, upon the axle of which is fixed a spur wheel *p*, which gears into a train of wheels terminating in the fan *q*. When the key be depressed the click takes hold of the wheel *o*, and the speed at which the arm *k* rises is regulated by the adjustment of the fan *q*; the screw *l* is connected to the terminal *r*, which is connected to the other pole of the battery (or to some immediate point in the battery), so that if the key be depressed for a longer time (say for sending a stroke) than the time at which the arm *k* arrives against *r*, the battery is placed upon short circuit, and no current flows along the line (or a part of the battery only may be cut off) if the connection with *r* made at an intermediate point. By this means a longer interval takes place after a long signal than after a short one, although the operator is manipulating the key with the usual pauses, irrespective of the currents actually sent into the line; and when once the rate of motion of the arm has been properly adjusted to the requirements of the line operated upon, the signals will come out at the other end with equal spaces between them.

A second arm, controlled by a fan to regulate the time of commencement of the currents after spaces of greater length than the spaces between the separate signals, may be used on circuits of very great length.

WHITWORTH'S IMPROVEMENT IN PREPARING PROJECTILES.

MR. JOSEPH WHITWORTH, of Manchester, whose name in connection with munition of war, is patent to the world, has patented a machine for preparing projectiles, which consists in placing the projectile in a chuck and turning the fore and rear parts simultaneously, or by consecutive operations, without removing the projectile from the chuck in which it is held. The engraving shows the machine employed for this purpose, having a holder or chuck, in which the projectile is held in the middle or intermediate of its length; the machine is arranged so that the chuck may be made to revolve, and that the tools which produce the required shapes to the ends may be moved up to and from the fore and rear parts respectively of the projectile, or the projectile may be held and presented to revolving tools.

The frame of the machine carries a central standard, in which revolves a conical chuck, driven by a band passing around the pulley; the said conical chuck carries a die which holds the projectile to be operated upon, which has previously been brought to the proper diameter and exterior form (excepting as respects its fore end) by pressure in dies; the fore end of the projectile and the hollow at the base has also previously been, by preference, approximately formed by pressure. D D are two slides, which carry cutter blocks; and cutters which are simply knives or blades of steel sharpened at the edge, are so formed as to give the required shape to the ends of the projectile. Two hand levers are employed moving on axes at their lower end, and carrying studs entering between collars on the slides D D, so that these may be forced up and withdrawn by means of them. The collars are adjustable to suit the required length of the projectile. The projectile is put into the die and removed therefrom by hand, the die fitting it with moderate tightness. If it be desired to turn cylindrical projectiles the die should be split or made in two parts, which are drawn together by means of a conical bearing, into which the die is forced, and so the projectile is held firmly whilst it is being turned.

In applying to projectiles suitable lubricating materials, a portion of the surface is coated with the lubricator, applied in spiral strips or ribs, that is to say, those parts are coated or more thickly coated which, when the projectile is in the rifled barrel, correspond with its grooves or recesses, by which means provision is made for easy loading without greatly reducing the diameter of the projectile. The projectile may be covered with paper or a thin metallic or other suitable coating to prevent the barrel from leading, and in that case the lubricator is applied or more thickly applied spirally upon the covering material.

This part consists of a piece of metal, bored and rifled internally, in the same manner as the rifle from which the projectiles are to be fired. Into this the projectile previously, by preference, covered with paper as is usual, is introduced at the top, and pushed down to the lower end of the instrument. The apparatus is slotted, and is, with the bullet within it, dipped into melted beeswax or other suitable lubricator, which, entering through the slots, coats the bullet at the parts which do not come in contact with the bore of the instrument, so that the bullet, when pushed out by the way it entered, is found to be lubricated as required. A plug is employed

to prevent the lubricating material entering the hollow at the base of the projectile.

When paper or similar covering is used, the end of the paper is twisted into the recess against the resilient material in the rear end of the projectile, and by causing the projectile to revolve in a lathe, or other suitable machine, the end of the paper is concentrically twisted and pressed into the recess against the resilient material by suitable tools, such as a piece of boxwood, with a conical recess at one end, and before or at the time the covering is put on suitable resilient materials made of fibrous or other elastic substances is inserted into the recess; this is done in order that the paper or other covering may be quickly and uniformly detached from the projectile in such a manner as not to interfere with its flight. The resilient material preferred is blotting paper reduced to a pulp by cutting and chopping. Finely-curled hair made into small spheres also answers the purpose.

GUYET'S COUPLING FOR UNITING PIPES.

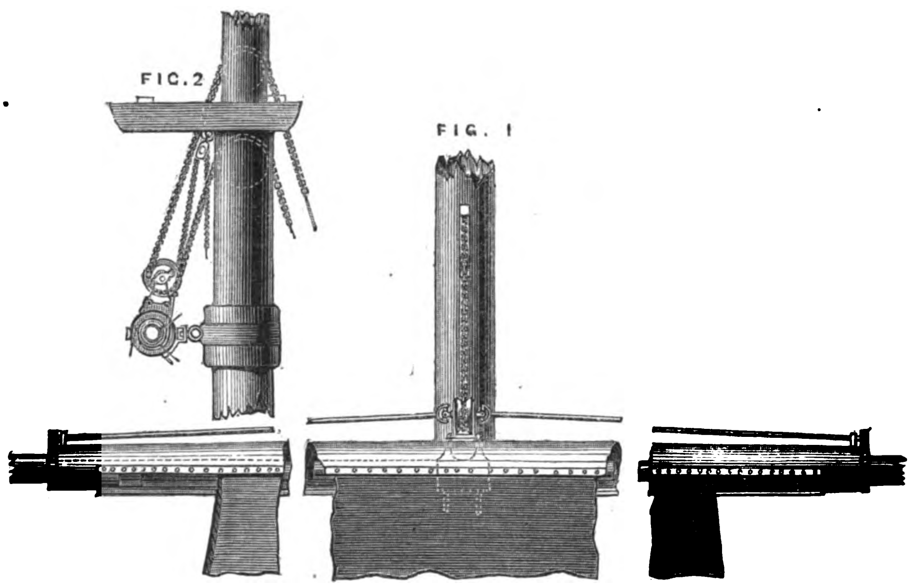
THE engraving illustrates an elastic coupling, for uniting pipes between locomotives and tenders, recently protected by M. P. J. Guyet, of Paris. The coupling consists of a central box *a*, furnished at each end with flanges, through which short pipes are inserted. These pipes, *b* and *c*, are free to move endwise in the box, and are kept steam or water-tight by suitable packing. The inner end of the pipe *c* has a stop on it to prevent it being drawn out so far as to be disengaged. The dotted lines indicate the various positions which may be taken by the pipes during the running of the engine, the flanges on the box being well mounted for that purpose. The pipe *a* has another pipe branching from the upper part, through which steam from the boiler may be drawn.

MEDHURST'S IMPROVEMENTS IN REEFING AND FURLING SAILS.

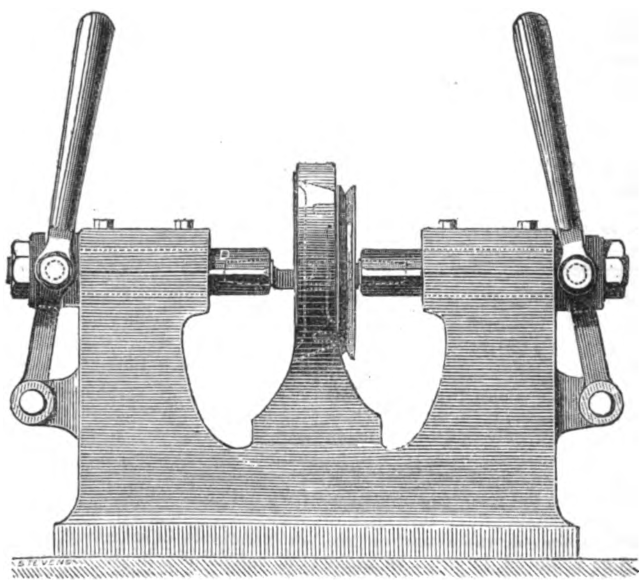
MR. J. MEDHURST, of Rotherhithe, has patented an improvement in apparatuses for reefing and furling sails, which he describes as follows:—In arranging topsails and other square sails, except t courses ,the yard is made of iron and hollow, and there is a bar or tube, by preference of iron, cased with wood, in the centre of the hollow part, and somewhat exceeding the breadth of the head of the sail in length, as represented in the engraving. This bar or tube is so arranged that it can revolve on centres or bearings at its ends. On this bar or tube the sail is laced, and when it is made to revolve the sail is wound around it. In order to reef the sail the yard is lowered, and the sail is at the same time wound up upon the bar or tube, which is caused to revolve. The apparatus is actuated in the following manner:—A chain from the deck passes through a sheave in the mast over the yard, and then around a chain wheel fixed to and above the yard at the slings. The chain then passes up and around a second sheave on the mast, and then returns to the deck, so that when the yard is lowered by slacking off one end of the chain, the whole weight of the sail, roller, and yard being pendant on the chain will cause the chain wheel to revolve. This chain wheel puts in motion two axes extending in either direction towards the extremities of the yard; these have pinions at their ends which gear with cog wheels at the ends of the roller to which the sail is attached. As a security against the roller being bent, or otherwise damaged by the wind blowing in the sail, there is a broad hook, made by preference of sheet iron, and so placed as to support the middle of the roller; this hook is connected with a purchase, so that when the sail is set, or after it has been reefed, the hook may be made to take the weight of the sail. Both ends of the chain are arranged so that they may be hauled on or slacked off from the deck, so that any desired amount of rotation may be given to the roller.

In arranging apparatus for reefing courses a modification is made in the construction. The roller and hollow yard is then made stationary, and the roller is driven from the deck by an endless chain passing round the chain wheel. It should be explained that by this invention the sail can be made as an ordinary topsail (or other sail), but without reef points, clew, or buntlines, the apparatus being made to stow the whole of the sail; or it may be made only to take in the reefs, and the sail may then be afterwards stowed in the usual manner.

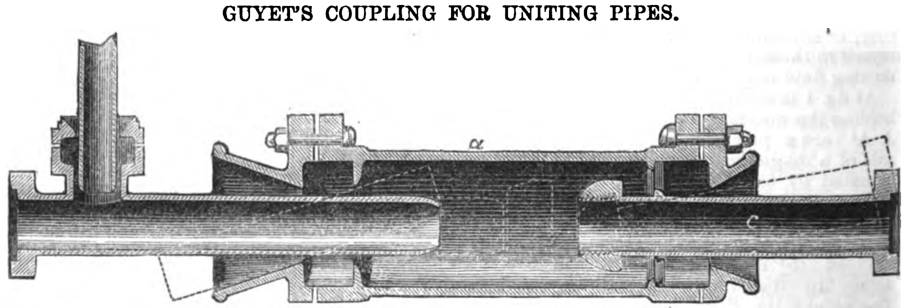
MEDHURST'S IMPROVEMENTS IN REEFING AND FURLING SAILS.



WHITWORTH'S IMPROVEMENT IN PREPARING PROJECTILES.



GUYET'S COUPLING FOR UNITING PIPES.



From an official report on the railways of India, recently published, it appears that we have already expended £40,000,000 on them, and have engaged to spend £17,000,000 more. This year we are to spend £17,000,000. We had opened 1,609 miles of railway when the year began, and are to open 1,181 more before it ends. And by making these lines we not only bring distant parts of the country into communication with each other, but give to large numbers of natives employment at once remunerative and instructive.

BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

(Continued from page 213.)

MATHEMATICAL AND PHYSICAL SCIENCE.

SECTION A (Mathematical and Physical Science) assembled, under the presidency of Professor Stokes, in a lecture-room in Trinity College.

BALLOON NAVIGATION.

Dr. Isaac Ashe, M.B., read a paper containing some suggestions on balloon navigation. He proposed a simple contrivance by means of which the opening of the escape-valve should depend, when desirable, on the relaxation of voluntary exertion on the part of the aëronaut, so that in case of insensibility occurring at great altitudes the valve should open spontaneously by means of a weight attached to its rope, thus obviating the danger to life incurred by Messrs. Glaisher and Coxwell, in their recent ascent from Wolverhampton, in consequence of their becoming insensible. Dr. Ashe also proposed the adaptation of screw propulsion to balloons, suggesting a very light screw, capable of elevation and depression through an angle of about 150 deg., so as to be capable of being hoisted while the balloon should be on the ground—of being used horizontally as a propeller, or ~~vertically~~ underneath the car, to cause a temporary ascent, as for the purpose of crossing a mountain range without loss of ballast or a descent without loss of gas. Such a screw, he considered, could be worked at small elevations—2,000 ft.—by the exertions of the aëronaut, and its advantages would consist in the conferring of definite direction and also of steering power, and in obviating the objection to hydrogen balloons, which consisted in the expense of the gas, as the descent could be effected without loss of gas. Hence smaller and much more manageable balloons might be constructed than those now used, and propulsion would be so much easier. Steering power being gained, Dr. Ashe hoped that a modification of shape might be found practicable, so as to present a minimum of resistance to the action of the screw. He proposed to steer by means of two small screws connected by a cranked axle placed at right angles to the axle of the propellor, and in front, so as not to interfere with the hoisting of the propellor. These steering screws should have their spirals turned the same direction, and by revolving them in one direction, or the reverse, the balloon might be made to rotate vertically, as might be desirable. The disagreeable rotation incident to balloons would also be thus obviated. Dr. Ashe suggested the employment of balloons in investigating aërial currents, and for the exploration of unknown continents, as Australia and Africa. Water—the great desideratum in such explorations—could be observed from an elevation when it would otherwise be passed by unobserved, and, a descent being effected, its position might then be taken by observation, and marked for the guidance of foot explorers. Similar remarks would apply to the discovery of the easiest routes by means of balloon observations.

Mr. James Nasmyth gave a *viva voce* account of his discovery of some remarkable details of the solar surface, which led to an animated discussion.

Professor Challis communicated two papers; one on the extent of the earth's atmosphere, and the other on the effect of the atmospheric refractions of the sun, moon, and planets. In the former it was maintained on theoretical grounds that the terrestrial atmosphere is definitely bounded, and does not extend so far as the moon; and reference was made to balloon ascents as likely to furnish data for an approximate calculation of the actual height. In the second paper reasons were given, from the results of calculations applied to astronomical observations, for inferring that the moon has an atmosphere of very small extent, the effect of which is perceptible in the occultations of stars.

Professor Hennessy read a paper on some characteristic differences between the configuration of the surfaces of the earth and moon. He pointed out that the peculiarities observed on the surface of our satellite could be ascribed to the sole action of volcanic forces, whereas those which we find on the earth result from a combination of volcanic and atmospherical agencies. In order more perfectly to study these contrasts he called attention to the most characteristic feature of all lunar volcanoes, namely, the ring or hoop-shaped crater, surrounded by circular or nearly concentric ridges. On the earth's surface volcanoes deviated more or less from this type, and if the deviations be due to the differences between terrestrial and lunar superficial forces, it must follow that such differences will be most distinctly manifested in those cases where such terrestrial forces possess the highest degree of energy. He illustrated this proposition by referring to the peculiar structure of the volcanoes in the island of Java, where the action of tropical rains and hurricanes has been effective in producing the very widest differences between the terrestrial volcanic summits and those observed on the moon's surface. Instead of the hooped structure of the latter, we see at Java specimens of radiating ribs, like those of a folded lamp-shade, or an umbrella half-closed—an appearance due to the very regular manner in which the tropical torrents scoop out the friable and scoriaceous summits of the craters.

Mr. Isaac Ashe, M.B., read a paper suggesting the use of compressed gas applied on a new principle to the elevation of a column of liquid for barometric purposes. He proposed to produce an invariable amount of compression of gas for this purpose by means of an invariable weight compressing in a vacuum a miniature gas reservoir carefully made air-tight by gilding. The pressure of the air and that of the column of liquid would then vary inversely, and by employing water or oil in the tube the same amount of variation in the height of the column might be obtained by this contrivance in a tube 42 inches long, as it is at present obtained with the water barometer having a tube of 34 feet in length. Mr. Ashe also proposed the employment of a bulb, with a very minute aperture at the top of the barometer tube by which to permit the necessary access of air to the top of the column of liquid; the advantage of this contrivance would be the prevention of constant and but momentary variations in the height of the column of liquid, owing to the passage of momentary ascensive gusts, which would otherwise cause such constant oscillations as to render so sensitive an instrument valueless.

MECHANICAL SCIENCE.

Section G, Mechanical Science, assembled in the Schools; Mr. W. Fairbairn, L.L.D. and F.R.S., President.

The President opened the proceedings by delivering an interesting address on the progress of mechanical science, especially during the past year. He then passed on to the Exhibition, and said:—"A very casual glance at this Exhibition, when compared with that of 1851, and that of Paris in 1855, shows with what intensity and alacrity the public mind has been at work since the people of all nations were first called upon to compete with each other in the peaceful rivalry of mechanical art. As one of the jury I examined with care and attention the whole of the mechanical inventions and machines in the International Exhibition. There is no new discovery of importance, except that the machines are more compact and better executed than at any previous exhibition. Taking the Exhibition as a whole, there is no very great, nor very important, discovery in mechanical science, but there is a great deal to be seen of a character both interesting and instructive. In land steam-engines there is nothing particularly attractive, if we except the growing importance of the horizontal, which is rapidly supplanting the beam, or vertical, engine. To the horizontal system may be applied economy in the first cost, and nearly equal efficiency in its application to mills and for manufacturing purposes. Another important feature in these engines is their smooth and noiseless motion, their compact form, and the facility with which they can be applied as helps, or assistants, to those of larger dimensions. They are, moreover, executed with a degree of finish and accuracy of workmanship which cannot easily be surpassed. In the agricultural department the same observations apply to this description of engine, where it is extensively used on a smaller scale. They are equally well made, and the country at large are chiefly indebted to our agricultural engineers for many ingenious contrivances and for their successful application, not exclusively to the farm, but to many other useful purposes in the economy of rural life. From the motive power employed in our manufactories and its adaptation to agriculture, let us glance at the beautiful execution, compact form, and colossal dimensions of our marine engines, and we shall find in combination simplicity of form, concentration of power, and precision of action never before equalled in this or any other country. Those who have examined the specimens of Mr. Penn and Messrs. Maudslay and Field in the International Exhibition must have been struck by the beauty and exactitude with which these engines are manufactured. (Hear, hear.) In this department of construction we are without rivals, and it is a source of pride that this country, as the first maritime nation in the world, should stand pre-eminently first as the leader of naval propulsion. In locomotive as in marine constructions we are not behind, if we be not in advance of, other nations; although it must be admitted that several splendid specimens of engines from France and Germany are exhibited by some of the best makers of those countries. There is, however, this distinction between the continental locomotives and those of home manufacture, and that is, in this country there is greater simplicity of design, compactness of form, and clearer conceptions in working out the details of the parts. These operations, when carefully executed to standard gauges, render each part of an engine a fac-simile of its fellow, and hence follows the perfection of a system where every part is a repetition of a whole series of parts, and in so far as accuracy is concerned, it is a great improvement on the old system of construction. The other parts of the Exhibition are well entitled to a careful inspection. In minerals and raw materials the collections are numerous and valuable, to an extent never before witnessed in any exhibition, and the articles, fuel and ores, will be found highly instructive. The machinery for pumping, winding, and crushing is upon a scale sufficiently large and comprehensive to engage the attention of the mechanic and miner, and it is only to be regretted that in every case competent persons are not in attendance fully prepared to explain and initiate the inexperienced student in the principles of the workings, and the cases of instruments so neatly classified and spread before him for instruction. In the machinery department, although there is nothing that strikes the observer at first sight as new, yet there are many useful improvements calculated to economize labour, and facilitate the operations of spinning and weaving, and in tool-making there never were at any former period so many hands and heads at work as on the occasion pending the opening of the Exhibition. I do not believe that at any former period there has been such an exhibition of machines and of tools, which are the creators and makers of the machines themselves. (Hear, hear.) Some of the tools, such as the turning, boring, planing, and slotting machines, are of a very high order, and the tool machinery for the manufacture of fire-arms, shells, rockets, &c., is of such a character as to render the whole operations, however minute, perfectly automaton, or self-acting, with an accuracy of repetition that leaves the article when finished identical with every other article from the same machine. Such, in fact, is the perfection of the tool system as it now exists that in almost every case we may calculate on a degree of exactitude that admits of no deviation beyond a thousandth part of an inch. Among the many interesting mechanical objects exhibited in the two annexes may be noticed as original the spool machine for the winding of sewing thread on bobbins; the machine for

making paper bags, invented by a pupil of my own; the saw riband machine, and others of great merit as regards ingenuity of contrivance and adaptation of design. In manufactures, in design, and in constructive art there is everything that could be desired in the shape of competitive skill, and, without viewing the success of the Great Exhibition of this year in a pecuniary point of view, we may safely attribute its great success to the interesting and instructive character of the objects submitted to public inspection." The President concluded with some observations on iron-clad ships, and recent gunnery experiments, with which our readers are conversant.

Mr. James Nasmyth described his solid bar valve motion, which as an improvement on the ordinary "link" valve motion was found most successful, and, since he contrived it in 1852, has been introduced with great success by Mr. Humphreys, as might be seen in his magnificent marine engines at present in the International Exhibition. The great simplicity of Mr. Nasmyth's solid bar link motion and its many practical advantages were, as it appeared, well calculated to cause its very general adoption, as the most simple and effective form of that important detail of the steam-engine.

Economizing Fuel.

Mr. Edward Ellis Allen, of London, read a paper "On the Importance of Economizing Fuel in Iron-plated Ships of War," and described a new double expansive marine engine, constructed according to his patent by Messrs. J. and G. Rennie, exhibiting photographs of the same, taken at their works. The author pointed out in detail the principles of marine engine construction which experience had shown to be absolutely essential in order to economize the fuel—viz., full expansion of the steam, surface condensation, superheating the steam, heating the feed water, jacketing the cylinders, and proportionately increasing the boiler power; and contended that in the ordinary marine engines now fitted to the iron-plated ships, though by the best makers, and of the most admirable workmanship, economy of fuel was impossible. The necessity of largely increasing the cylinder capacity to admit of expansive working, rendered an entire change in the forms of marine engines imperative, the large diameter short-stroke engines of the present day consuming as much as 4½ lb. of coal per indicated horse power per hour, whereas double expansive engines, on the plan suggested, and every way suited for Government vessels, would save 50 per cent. of the present consumption of fuel. The amount yearly voted for coals for the navy now exceeds £300,000 per annum, and the author stated it as highly probable that it would rise to upwards of a million sterling, when our iron-cased fleet was complete, unless changes were made in the construction of engines employed in war steamers. The engines referred to had been frequently submitted to our Admiralty, and the author hoped there were prospects of his plans being tried, Messrs. Rennie being prepared to guarantee their efficiency and economy. He concluded by referring to the engines proposed by him in 1855, and similar in principle to those made by Messrs. Rennie, but worked by means of a trunk instead of double piston rods, the former plan being, he believed, adopted for the engines of the "Poonah," now constructing for the Peninsular and Oriental Company by Messrs. Humphreys and Tennant.

Mr. Scott Russell said they were all agreed that the short-stroke engine was wasteful of fuel in marine engines, and of the powers to gain speed. The importance of saving fuel to the Admiralty was so great that they ought to take the lead in experiments for this purpose. Without saying that Mr. Allen's invention was the best that could be devised, he would say that the combination he suggested offered considerable hopes that an economy of fuel would be attained without reducing the work performed by the engines.

The President said that he had always found that experimental tests in working steam by expansion were always more successful than they were found to be in the actual working. Unless, therefore, the experiments were carried out on a large scale and on a long voyage, and an average obtained, they could not be considered altogether satisfactory.

Mr. Allen said that the "Moolton's" voyages gave very successful results.

After a short discussion,

The President said that these inquiries were of great advantage in economizing fuel in marine and other engines, and begged to move the thanks of the section to Mr. Allen.

The motion was carried.

A New Marine Boiler.

Dr. F. Gramaldi read a paper on "A New Marine Boiler," the principle of which was that the whole boiler, which consisted of a cylinder nearly filled with tubes, was kept slowly revolving during the time of working. Detailed drawings were exhibited of a boiler of 100-horse power, which occupied less than half the space of ordinary marine boilers of the same power, and was of less than half the weight. The fire-grate, placed beneath the boiler, has the whole shell brought gradually over it, the hot gases passing through all the tubes, part of these being covered by the water and part in the steam space, thus rendering the boiler a steam generator and a superheater.

In the discussion which followed, and in which Mr. Siemens, Mr. Allen, and Mr. Scott Russell took part, the general principle of the boiler was fully approved, and it was stated that Mr. J. Stewart, of Blackwall, was about to construct one suitable for a steam vessel. The plan had been tried on land, and details of the experiments were given.

Mr. Thorold read a paper "On the Failure of the Middle Level Sluice, and the means of preserving such sluices." Mr. Thorold attributed the failure to the silty nature of the soil being too weak to withstand the great hydrostatic pressure brought against it at high tides, and he proposed to remedy and secure such sluices from the possibility of failure in future by the erection of a duplicate sluice at the back of the sea-sluice, for the purpose of keeping up a head of tidal water to a medium height between the two sluices when the sea-sluice was closed by the tide, and he showed by a diagram how this was to be accomplished, avoiding three-fourths of the usual pressure without detracting from the utility of the sea-sluice.

Mr. Vignoles, while fully approving Mr. Thorold's plan for securing such sluices, suggested that, as there was to be an excursion to the dam and syphons on Saturday next, and as there were so many questions arising out of the failure, legal and otherwise, he thought it most prudent that the discussion on Mr. Thorold's interesting paper should be deferred until Monday next, when, after having seen the site of the old sluice and dams, members would be in a better position to discuss the whole subject of failure, and the questions of dams and syphons.

Mr. Vignoles' suggestion was approved by the section.

Middle Level.

On Saturday a large party of members of the association—upwards of 90 in number, and comprising among them many of the more eminent members of Section G—made an excursion to Lynn to inspect the works which are being constructed at the Middle Level for repairing the mischief caused by the late disastrous irruption of waters. Mr. Appold, the amateur engineer, whose centrifugal pump has given him worldwide fame, projected and arranged the excursion. On arriving at the spot the party were received by Mr. Linn, the resident engineer, who, in conjunction with Mr. Appold, explained the apparently complicated arrangements so succinctly that they became perfectly intelligible to all his auditors. It appears that the waters are to be carried over a dam full 20 feet high, by means of syphons, which at low water discharge themselves into a canal connected with the sea by means of the river Ouse. Six of these siphons have already been laid and tried, and are found to answer so satisfactorily that the number is being increased to 16, which are to be completed before the end of November. They are of uniform size, 3 ft. 6 in. diameter, 150 ft. long, rising 20 ft. in a curved line, with valves at both ends, and are laid in a row 18 in. apart. At the experiment made with the first six siphons it was found that they discharged 50,000 gallons a minute—an immense advantage as well in efficacy as in the saving of expense over the usual appliance of steam pumping. For this substitution the parties interested are, it was stated, mainly indebted to the ingenuity of Mr. Appold. To set the siphons going and to pump out the air whenever it interposes, a small steam-engine has been erected, of 10-horse power, working three air-pumps, of 15 in. diameter and 18 in. stroke.

After a full hour's inspection the party returned in carriages to Lynn, where at the Duke's Head they found an elegant repast spread for them by their liberal host. After some lively speeches the party returned to Cambridge by train.

Among the company were:—Mr. Tite, Mr. H. Marsh, Mr. W. Fairbairn, Mr. James Napier, Dr. Daubeny, Mr. Scott Russell, Rev. Dr. Robinson, Mr. Charles Barry, Mr. Wollaston Blake, Mr. C. Vignoles, Mr. Charles Siemens, Mr. R. Wilkinson, Mr. Le Neve Foster, Mr. H. G. Bohn, Mr. C. White, Mr. T. Webster, Mr. C. Brooke, Mr. Robert Mylne, &c.

Mechanical Science.

This section met this morning in the schools, Mr. W. Fairbairn, LL.D., F.R.S., in the chair. There was a very numerous attendance. Among those present were Sir W. Armstrong, Sir E. Belcher, the Vice-Chancellor, Professor Robinson, Mr. Napier, Mr. Whiteside, Mr. Nasmyth, Mr. Aston, Mr. Scott Russell, &c.

Steamships.

The first paper brought before the section was the report of the Steamship Committee, of which Mr. W. Smith, C.E., gave a summary. The following is the concluding passage of this very voluminous and valuable document:—"Your committee have pleasure in reporting very satisfactory progress, and that they have now a larger amount of useful information placed at their disposal. There is much greater interest taken in the objects of the inquiry, and a still increasing number of observers have adopted the forms of the committee for recording the performances of vessels. The importance of the information collected by your committee is attracting the attention of steamship owners, as well as scientific investigators, and it is hoped the result of greater efficiency and economy in the application of steam, as well as in improvements in the construction of steam vessels, will be the results of these reports; and your committee have reason to believe that considerable advantages have already been derived from their labours by steamship owners. The committee purpose to act upon a suggestion made to them of forming a list of the engineers of the several classes employed in the mercantile steam service who have, with the sanction of their owners, supplied your committee with returns of the performances of ships under their charge, to which reference may be had by such members of your association as are interested in the subject, and with a view to afford opportunities for the advancement of such engineers as have shown the greatest amount of scientific ability in connexion with their calling. Your committee have determined to act upon a suggestion by which the performances of some steamships which are at present withheld may in future be supplied for the use of the committee—viz., that such returns shall be published under a distinguishing number, instead of publishing the name of the vessel, her builders, and the constructors of her machinery, and that the latter particulars shall only be disclosed with the consent of the owners. Your committee continue to receive, from steamship owners and engineers, invitations to be present at the trials of steamships. In conclusion, your committee believe that their labours have already

been productive of considerable advantage; that the objects with which they were appointed are being rapidly attained; and that, by continuing their labours, the machinery they have succeeded, after considerable trouble, in organizing will be productive of the utmost benefit to those engaged in steam navigation; and they have reason to believe that the future collection of the returns will be a comparatively easy task."

MECHANICAL PROPERTIES OF PROJECTILES.

The president made some observations on the results of some experiments on the "mechanical properties of projectiles." He commenced by stating that, in the investigations which had taken place with regard to projectiles and armour-plated ships, one great difficulty that had arisen was to get plates of sufficient thickness, and vessels of sufficient tonnage to carry those plates. It appeared that they were limited to plates of five inches in thickness; with plates heavier than that a ship would not be what was technically called "lively." He had attended the experiments at Shoeburyness from the commencement, and they had reference to the force of impact. He would state the results of the more recent experiments, which had not yet been published. The first series of experiments had reference to the quality of the plates and the properties of the iron best calculated to resist impact. There were three qualities required—1st, that the iron should not be crystaline; but, 2nd, that it should be of great tenacity and ductilty; and, 3rd, that it should be very fibrous. The president produced specimens of spherical and flat-ended shot, and proceeded to give the statical resistance of each.

The mean statical resistance to crushing of the two flat-ended specimens of cast iron is 55·32 tons per square inch. The mean resistance of the two round-ended specimens is 26·87 tons per square inch. The ratio of resistance, therefore, of short columns of cast iron with two flat ends to that of columns with one flat and one round end is as 55·32 to 26·87, or as 2·05 to 1—an extremely close confirmation of Professor Hodgkinson's law. Applying this same rule to the steel specimens, it would appear that the flat-ended shot would have sustained a pressure of 180 tons per square inch before fracture. In the experiment it actually sustained 120 tons per square inch without injury, excepting a small permanent set. In the experiment with cast iron the mean compression per unit of length of the flat-ended specimens was ·0,665, and of the round-ended ·1,305. The ratio of the compression of the round-ended to the flat-ended was, therefore, as 1·96 to 1, or nearly in the inversed ratio of the statical crushing pressures. Applying this law to the case of the steel flat-ended specimen, we may conclude that the compression before fracture would have been only ·058 per unit of length. The determination of the statical crushing pressure of the flat-ended steel shot as 180 tons per square inch and its compression as ·058 is important, on account of the extensive employment of shot of this material, size, and form in the experiments at Shoeburyness. In the case of the lead specimens, the compression with equal weights was the same, whether the specimen were at first round-ended or flat-ended. This is accounted for by the extreme ductility of the metal and the great amount of compression sustained. In regard to the wrought-iron specimens, it may be observed that no definite result is arrived at, except the enormous statical pressure they sustain, equivalent to 78 tons per square inch of original area, and the large permanent set they then exhibit:—

	Statical resistance in tons per square inch.	Dynamical resistance in foot lb. per square inch.
Cast-iron, flat-ended ...	55·32	776·8
Cast-iron, round-ended	26·87	821·9
Steel, round-ended ...	90·46	2,515·0

In the experiments on the wrought-iron specimens, the flat-ended steel specimen, and the lead specimens, no definite termination was arrived at, the material being more or less compressed without any fracture ensuing. Hence it is difficult to draw conclusions from these results, but the great amount of work expended in compressing the wrought-iron specimens, amounting in one case to 4,340 foot lbs., or nearly twice as much as was required to fracture the round-ended specimen of steel. On the other hand, the low statical resistance of lead corresponds with a dynamical resistance almost equally low. The work required to crush similar specimens of cast iron is nearly the same whether the ends be rounded or not, the round-ended requiring rather more work to be expended than those with flat ends. It is, therefore, obvious that there is no analogy between the law deduced for statical forces by Professor Hodgkinson and the law regulating the dynamic resistance. The mean resistance of the specimens of cast iron is 800 foot lb. per square inch; that of the specimen of steel is 2,515, or rather more three times as much. The conditions which would appear to be desirable in projectiles, in order that the greatest amount of work may be expended on the armour plate are—1st, very high statical resistance to rupture by compression. In this respect, wrought iron and steel are both superior to cast iron; in fact, the statical resistance of steel is more than three times, and that of wrought iron more than two-and-a-half times, that of cast iron. Lead is inferior to all other metals experimented on. 2nd, resistance to change of form under great pressures. In this respect hardened steel is superior to wrought iron. Cast iron is inferior to both. The shot which would effect the greatest damage to a plate would be one of adamant, incapable of change of form. Such a shot would yield up the whole of *vis viva* to the plate struck; and, so far as experiment yet proves, those projectiles which approach nearest to this condition are the most effective. (Cheers.)

The president stated that steel shots might be made at comparatively small cost. Mr. Bessemer had informed him that if he had a large order he could produce steel shot at very little more than the price of wrought iron. But if ingots as cast had to be rolled or hammered to give them fibre, they would cost something like £30, instead of £8 or £10 per ton.

The thanks of the section were given to the president for his valuable paper.

PENETRATION OF PROJECTILES.

Mr. T. Aston, M.A., read a paper on "Rifled Guns and Projectiles adapted for Attacking Armour-plates." After alluding to the interest with which the contest between artillery and armour-plates has been watched by the country, he explained what was the actual condition of this important question so late as May last by quoting a statement made by Sir W. Armstrong at a meeting of the United Service Institution on the 20th of May last, as follows:—"It certainly may be said that shells are of no avail against iron-plated ships; but, on the other hand, I may say that neither 68-pounder nor 110-pounder guns, with solid round shot, are effective against such iron vessels. The fact is, what we want is a gun, in addition to our 110-pounder rifled gun, especially adapted for breaking through iron plates. That is what we are in want of now." This candid confession is startling when it is considered that long ago France armed her Gloires and Normandies with rifled 90-pounders proved to be efficient against iron-plates, and it caused the country serious anxiety to hear Her Majesty's ministers state, as they did in Parliament last session (of course on the authority of their scientific advisers), that after all the vast expenditure upon our new artillery, the navy of England is compelled to arm her navy with the old smooth-bore, and that is the best gun the navy actually possesses, though declared by Sir. W. Armstrong to be so inefficient. Such being the state of the question a few months ago, Mr. Aston proceeded to consider, first, the reason why the artillery hitherto employed in the service (including rifled guns and smooth-bores) has always failed to make any impression on the plated defences at ordinary fighting range; and, secondly, by what means artillery science has lately reconquered its lost ground. Three conditions were laid down as necessary to enable artillery to attack successfully armour-plate defences—1st, the proper projectile must be of the proper form; 2nd, of the proper material; and 3rd, be propelled from a gun able to give it the necessary velocity. The artillery of the Ordnance Committee failed because they utterly neglected the first two conditions, and had recourse to the brute force of the smooth-bore for the third. The expression accepted as representing the penetrating power of shot was "velocity squared, multiplied by weight," but the form of the shot and the material were conditions altogether omitted from the expression, and the importance of the omission will be obvious at once if an analogous case, say a punching machine employed to perforate wrought-iron plates, be taken. What would be the result if the punch, which is made of suitable shape and material, were removed, and a round-headed poker of brittle cast-iron or soft wrought-iron were substituted in its place? The great importance of velocity was conceded at once; it is a *sine quâ non* condition, but there has been great misconception in supposing that the old smooth-bore gives a greater initial velocity than the rifled gun, as the results obtained will show. The average initial velocity of the 68-pounder is, in round numbers, 1,600 feet per second, with a charge of powder one-third the weight of the shot, the length of the shot being, of course, one calibre. Sir W. Armstrong stated that, with a charge of powder one quarter the weight of the shot, he obtained with his rifled gun an initial velocity of 1,740 feet per second. He did not state the length of his projectile. Mr. Whitworth, with a projectile two calibres long, obtains an initial velocity of 1,900 feet per second, and with a projectile one calibre long, like that of the smooth-bore, an initial velocity of 2,300 feet per second, being greater than that of the smooth-bore in the proportion of 23 to 16. The following table shows the actual results obtained by various guns:—

Gun.	Range.	Projectile.	Powder Charge.	Penetration into Armour Plate.
Armstrong 110-pounder	200	110lb. solid	14lb.	1½ to 2 inches.
68-pounder smooth-bore	200	68lb. solid	16lb.	2½ to 3 inches.
Whitworth 70-pounder	200	70lb. shot and shell	12lb.	Through plate and backing.
Whitworth 120-pounder	600	130lb. shell	25lb.	Through plate and backing.

The first two results show that the Armstrong rifled gun is a worse compromise than the old gun it was intended to supersede. It is worthy of notice, that the velocity of the Whitworth heavy projectile after traversing 600 yards (a good fighting range) was 1,260 feet, being 50 feet greater than the initial velocity of the Armstrong projectile, which is 1,210 feet at the muzzle of the gun. The total results in respect of penetration being so decidedly in favour of Whitworth, it follows that he has adopted the best compromise, by combining all three necessary conditions of proper form and material of projectile and sufficient velocity. That the velocity, though perhaps at the muzzle of the gun slightly below that of the smooth-bore, is sufficient, when combined with proper form and material of projectile, is shown by the penetration result, which in the case of the Whitworth is through and through both armour-plate and backing; in the case of the smooth-bore it is barely through half the armour-plate, and in the Armstrong is not half through. The form of projectiles, both shot and shell, employed by Mr. Whitworth for penetrating armour-plates were then described. The material of which the projectile is composed is what is termed homogeneous iron, combining the toughness of copper with the hardness of steel. It undergoes a carefully-regulated process of annealing. The same metal is used for the Whitworth field guns, and practical improvements now enable it to be worked in masses of any requisite size, whose quality may be henceforth depended upon with certainty. Mr. Whitworth is, therefore, now making his heavy ordnance with both interior tubes and outer hoops of homogeneous metal of the improved manufacture, so that the guns will be constructed throughout of one uniform metal, without any weld-

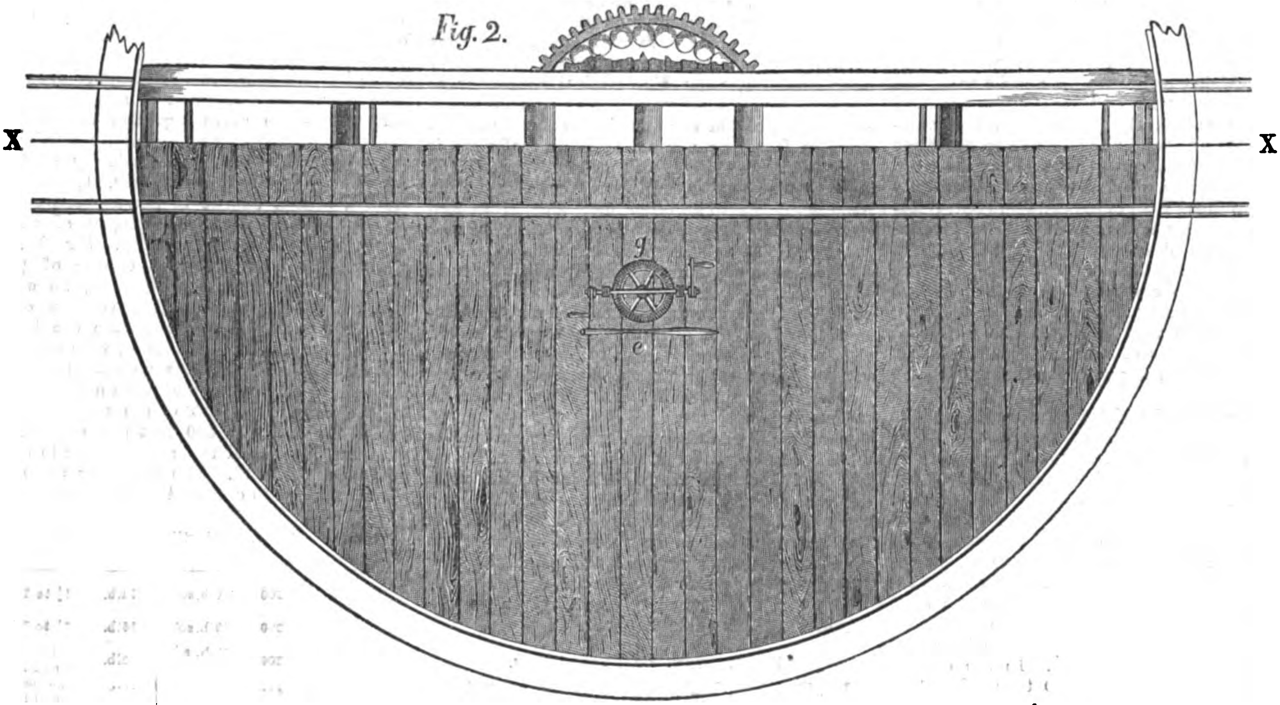

Fig. 2.

ing at all. Experience justifies the expectation that they will be free from the objections which it is well known are inherent in all welded guns, and be fully able to resist the severe and searching strain that is sure, sooner or later, to disable a gun built up of forged coiled tubes, if it be called upon to do its full work, by discharging heavy projectiles at efficient velocities.

Mr. James Nasmyth, F.R.A.S., said the steam ram was an old subject with him. A plan was proposed by him to the Admiralty so long ago as 1845. He thought the more destructive you can make the attack on your adversary the better. It was not right to be torturing your enemy by drilling numerous small holes in him; it was like taking a whole day to draw a tooth. (A laugh). His idea was to make one large hole and sink the ship at once with the enemy. (Cheers.) It was a question of *momentum*. The first practical ram was the Merrimac, but the Southerners made a mistake in giving her a sharp end—it should be blunt, and such was the original plan of the author, nor had he seen any reason to alter his views. The vessel must present as low an angle as possible to turn shot, but she must also have strength in the direction of her length, and use the utmost possible amount of steam; and, to meet the objection that the impact might destroy the engines, which he did anticipate, he would place the engines on a slide, with buffer arrangements. With such a vessel he would dash into the "Warrior" as into a bandbox. (A laugh.) The plates would be crushed at once. He hoped the Admiralty would devote a thousand pounds or two to try the effect of a ram against an old hulk, the ship "Trusty," and afterwards at the "Warrior" herself. (Cheers.)

(To be continued.)

WARD'S SELF-CENTERING TURN-TABLE.

This description of railway turn-table is rather novel, from the fact of there being no central or guiding pivot, thereby allowing the platform freedom to yield in its revolution without injury, making it capable of sustaining more weight, and cheaper in its original cost than the ordinary ones in use.

The illustrations represent an engine-table of this description, 45 feet diameter, as used in Canada, the United States, Central and South America, notices of which have from time to time appeared in our transatlantic contemporaries, and we also learn that they are being introduced on some of the principal lines diverging from London, and many continental railways, with a constant increasing demand from all parts of the world. Having witnessed the one exhibited in the north end of the eastern annexe of the International Exhibition by Messrs. Lloyds, Fosters and Co., of Wednesbury, makers, we find our convictions realized as to the merits of these tables. The one referred to seems to improve with use, and has it is said made more revolutions than any table now in use, and from all appearance is likely to continue for years without repair or injury.

Fig 1 of the accompanying illustrations represents an elevation of this description of table on the line of X X Fig. 2, and Fig. 2 represents the turning platform with half the decking removed, the truss work and covering of which are of wood.

A company has been called into existence for the formation of a new railway for North Somerset, to be called the "Bristol, North Somerset, and South Western Junction Railway Company."

RAILWAY BRIDGE OVER THE GROSS-ACHEN.

The following figures give some sketches of the railway bridge over the Gross-Achen, on the line from Munich to Salzburg, which may be looked upon as representing the standard arrangements of the details in Pauli's bridges, as manufactured by Messrs. Klett & Co., of Nürenberg, Germany.

Figs. 1 and 2 are :—view, plan, and cross section of such a structure. The tension bar (Fig. 3) consists of a number of flat irons, connected together by conical bolts, the joints being effected either by one flat iron running throughout the length of the bar for that special purpose, or by extra joint plates. If the section of the tension bar by required to be great, two tension bars, composed of flat irons, are laid side by side, for the reason that the quality in flat iron of a small section is to be more depended upon than that in large sections, and at the same time bolts of an inconvenient length are avoided.

The compression bar (Fig. 4) is generally arranged with a trunk section, and its dimensions determined proportionately for the width of the panels of the bridge. To save material as much as possible, its greatest amount is accumulated into the corners of the section. In case of very large spans, as in the Mayence Bridge, the two compression bars are firmly connected together. (Fig. 5.)

That part of the structure by which the tension and the compression bar is to be connected together, the so-called "shoe" (Fig. 6) must present an ample amount of space to do this, having at the same time strength enough to resist the tendency of shearing off over the resting point of the beam.

RAILWAY BRIDGE OVER THE GROSS-ACHEN.

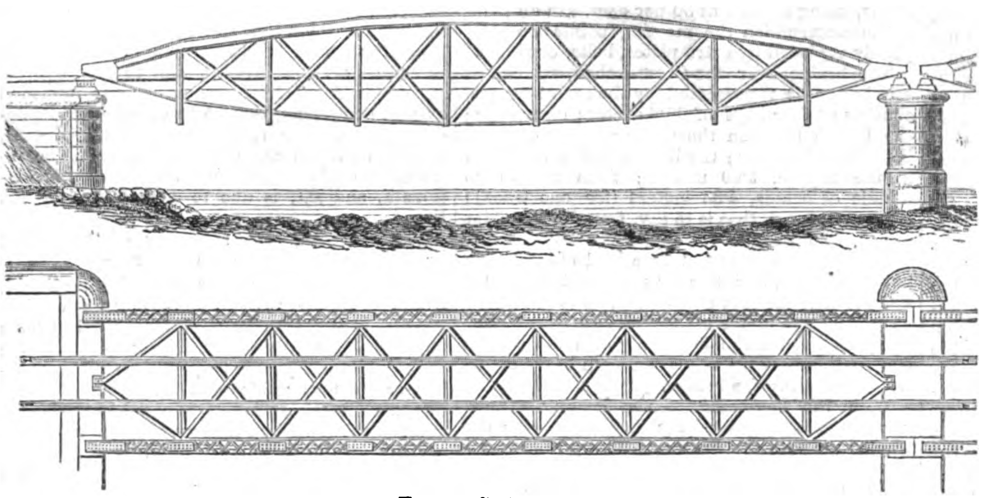

FIG. 1.—Scale 1-250.

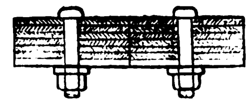

FIG. 3.—Scale 1-10.

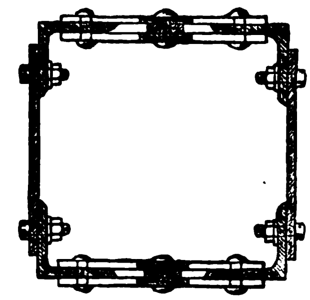

Fig. 4.—Scale 1-10.

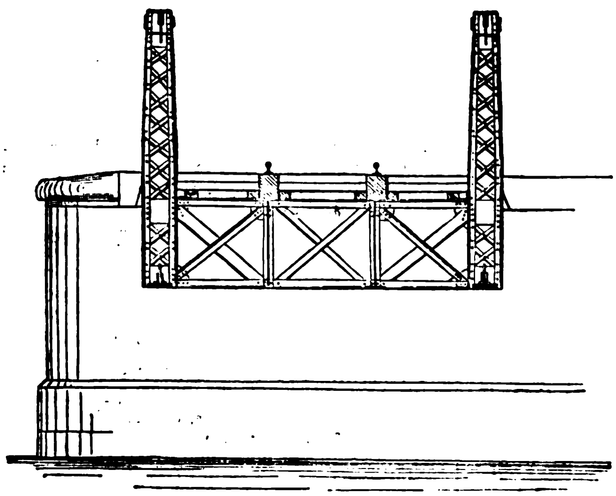

FIG. 2.—Scale 1-100.

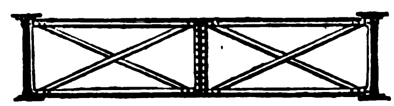

FIG. 5.—1-100.

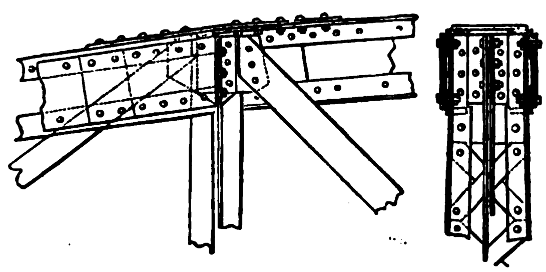

FIG. 7.—Scale 1-25.

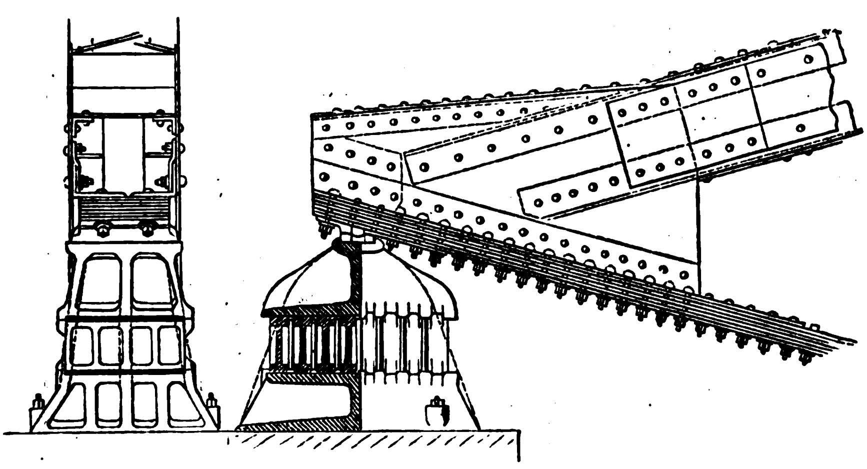

FIG. 6.—Scale 1-25.

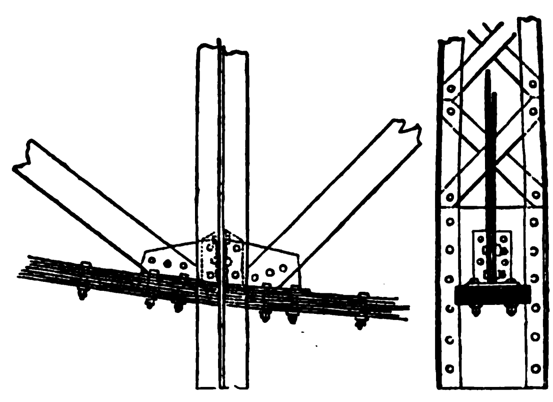

FIG. 8.—Scale 1-25.

The vertical posts are arranged of angle iron, so as to present in their sections either the "cross" or "double T" form. At the top they are attached to the compression bar by bolts, according to the forces acting upon them, and beneath they rest upon the tension bar in such a manner that no transversal movement is possible (Figs. 7 and 8).

As the girders carrying the platform are to be attached into those posts, they have, according to the position of the platform, which lies either under or over, or in the geometrical axis of the beam, to project either higher than the compressions or beneath the tension bar. By this the section of the posts, whether in the cross or double T form, is determined.

The sectional dimensions of all prismatic parts of the construction, on which compressive forces are acting upon, are determined by the formulæ

$$K^d = \frac{K_0}{1+\frac{1}{8}\cdot\frac{\omega}{\mu}\cdot\frac{K_0}{\epsilon}\lambda^2}$$ it being:—

K^d the bearing power per unit of the section.

K the maximum of working strain.

ω the area of the prism.

μ the momentum of the figure of the section.

λ the free length between the compressive forces.

The formulæ holds good till $K_0 = 1{,}000$ kilog. per square centimeter (6·46 tons per square inch).

The diagonals consist of flat irons, which are bolted at their ends to pieces of sheet iron, which are properly connected to the compression, the tension bars, and the posts. (Figs. 7 and 8.

The whole construction rests at each end by planed steel plates on cylindrical ones of great

radius. By this arrangement the beam may deflect freely, without producing a one-sided pressure of great intensity upon the supporting plates, and dispensing at the same time with wooden underlays (as used in large bridges in England, and in some instances in Switzerland). A longitudinal, as well as a transversal, dislocation of those plates is obviated by projections acting like teeth. The lower of those plates are connected to cast-iron chains (Fig. 6), one of which rests directly upon the pier, while the other stands on stilts, which allows for the longitudinal differences in length of the bridge, caused by the change of temperature. To keep the parallelism, the stilts have also projections, or teeth, which fit into like ones of the rolling chair and the bottom plate. The cylindrical faces of the stilts are turned and move on even planed ones. The stilts are used in the shape of *sections* of *cylinders*, as it is obvious that the pressure to which cylinders may be exposed increases with the diameter of them, thus saving by a greater depth in the total length of the pieces, and by that in the dimensions of the supporting plates. The dimensions of the stilts are so determined, that, for different spans, the maximum inclination, caused by the extremes of temperature, are nearly of an equal amount in the respective different spans. The pressure per unit of length is taken in proportion to the radius r, and is for cast iron, the radius being given in centimeters, equal to 12 r kilog. per centimeter run, which, within the limits in which r varies, is quite admissible.

The transverse girders carrying the platform are, in railway bridges, constructed on the triangular system. In larger spans, longitudinal extra girders are wanted to transmit the load of the platform to the points of construction of the chief beams. They lie either in the same plain with the chief beams, and carry the intermediate transverse girders, or are fixed *between* the transverse girders and carry the direct underlays of the rails. Those parts having first to take up the effects of the moving load are to be constructed of a greater relative strength, that is to say, with a smaller figure for the working strain, as in the principal beam.

The bracings are obtained by flat irons, which are bolted on at its ends only, being at the same time stretched to a certain length. The use of intermediate arrangements for the regulation of the length of those bracing ties, is objected to, considering that a well designed iron-bridge, under the ordinary traffic, always keeps its regular position, and thus an arbitrary alteration of length can do nothing but harm.

By experiments carried on at Messrs. Klett and Co.'s it was found that rolled iron has less strength in its longitudinal direction than its transversal, which has to be borne in mind in designing the positions of the bolts in joining flat iron. Thus the extreme hole is so far back from the edge that the remaining longitudinal section is as great as the area of the section of the bolt. Besides this, the relative position of the bolts is changed in such a manner that the section of the flat iron is weakened only by one hole, the oblique area between the first and second transmitting bolt being 20 per cent. larger than the transverse section in action.

The same experiments have shown, that, to obviate jolting at the edge of the hole, the bolts (or rivets) should not exceed a certain diameter for a certain thickness of the flat iron to be fastened. The limits at which this jolting takes place was found to be at a pressure of 4,300 to 6,000 kilog. per square centimeter of the bolt's face of action. The *limit of elasticity* of wrought iron being 1,600 kilog. per square centimeter (circa 10 tons per square inch) it was determined that the bolt's face in action (being the product of its diameter by the thickness of the iron to be fastened) ought never to be less than 4-10ths of the whole area of section of the bolt.

By this means the incertitude in determining the dimensions of the bolts (or rivets) to be used for a certain joint, is dispensed with. To rely with the utmost security on the complete action of the joints, the section of turned bolts are taken 20 per cent. higher than the respective effective area of the flat iron, this addition, in using hot rivets, being as high as 50 per cent. In all parts of the construction the meeting points are completely replaced by extra plates, bolts, or rivets.

The bridge over the Gross-Achen, which, as said before, is represented by the above figures, consists of four bays of 26·6 meters clear span; the length between the resting points of beam being 27·26 meters; the height of the beams is, in the middle, 3·60 meters; from middle to middle of beams, 4·83 meters (for one track); depth of girder, that is to say, from lowest point to rail, 1·50 meters.

The bridge was tested by a load of 5·14 tons per meter run, and this was effected in such a manner that the first pile of rails, up to the above weight for one meter of the bridge's length, was completed before the beginning with the second one, such having the effect of a train of the above weight entering the bridge.

With the beginning of the loading a most regular transmission of the deflection over the whole span was observed, and a very regular increase of it when the load was proceeding.

When the continuous equal loading of the structure with 5·14 tons per meter run was completed, the elastic deflections were as follows:—

Point of Construction. No.	Distance from Resting Point, No. 1, in Meters.	Observed Elastic Deflection, in Millimeters.	Calculated Deflection in Millimeters.
0	0·0	0·0	0·0
1	3·13	8·2	7·3
2	6·13	12·8	12·5

7	21·13	12·8	12·5
8	24·13	7·3	7·3
9	27·26	0·0	0·0

N.B.—25 millimeters 1 inch.

The permanent *deflection was less* than one millimeter.

THE FORM AND MOTION OF WAVES.

British Association, 1862, Section A.

Abstract of an Investigation on the Exact Form and Motion of Waves at and near the surface of Deep Water. By William John Macquorn Rankine, C.E., LL.D., F.R.S., L.S., and E., &c.

The following is a summary of the nature and results of a mathematical investigation, the details of which have been communicated to the Royal Society.

The investigations of the Astronomers Royal, and of Mr. Stokes on the question of straight-crested parallel waves in a liquid, are based on the supposition that the displacements of the particles are small compared with the length of wave. Hence it has been very generally inferred that the results of those investigations, when applied to waves in which the displacements are considerable, as compared with the length of wave, are only approximate.

In the present paper, the author proves that one of those results, viz., that in very deep water, the particles move with a uniform angular velocity in vertical circles, where radii diminish in geometrical progression with increased depth, and consequently, that surfaces of equal pressure, including the upper surface, are trochoidal, is exact for all possible displacements how great soever.

The trochoidal form of waves was first explicitly described by Mr. Scott Russell; but no demonstration of its exactly fulfilling the cinematical and dynamical conditions of the question has yet been published, so far as the author knows.

In "A Manual of Applied Mechanics" (first published in 1858), the author stated, that the theory of rolling waves might be deduced from that of the positions assumed by the surface of a mass of water revolving in a vertical plane about a horizontal axis; but as the theory of such waves was foreign to the subject of the book, he deferred until now the publication of the investigation on which that statement was founded.

Having communicated some of the leading principles of that investigation to Mr. William Froude, in April, 1862, the author was informed by that gentleman, that he had arrived independently at similar results by a similar process, although he had not published them. The introduction of proposition II. between propositions I. and III. is due to a suggestion by Mr. Froude.

The following is a summary of the leading results demonstrated in the paper:—

Proposition I.—In a mass of gravitating liquid, whose particles revolve uniformly in vertical circles, a wavy surface of trochoidal profile fulfils the conditions of uniformity of pressure; such trochoidal profile being generated by rolling, as the under side of a horizontal straight line, a circle whose radius is equal to the height of a conical pendulum that revolves in the same period with the particle of liquid.

Proposition II.—Let another surface of uniform pressure be conceived to exist indefinitely near to the first surface; then if the first surface is a surface of continuity (that is, a surface always traversing identical particles) so also is the second surface. (Those surfaces contain between them a continuous layer of liquid.)

Corollary.—The surfaces of uniform pressure are identical with surfaces of continuity throughout the whole mass of liquid.

Proposition III.—The profile of the lower surface of the layer referred to in Proposition II. is a trochoid generated by a rolling circle of the same radius with that which generates the upper surface; and the tracing arm of the second trochoid is shorter than than of the first trochoid by a quantity bearing the same proportion to the depth of the centre of the second rolling circle below the centre of the first rolling circle, which the tracing arm of the first rolling circle bears to the radius of that circle.

Corollaries.—The profiles of the surfaces of uniform pressure, and of continuity, form an indefinite series of trochoids, described by equal rolling circles, rolling with equal speed below an indefinite series of horizontal straight lines. The tracing arms of those circles (each of which arms is the radius of the circular orbits of the particles contained in the trochoidal surface which it traces) diminish in geometrical progression, with a uniform increase of the vertical depth at which the centre of the rolling circle is situated. The preceding propositions agree with the existing theory, except that they are more comprehensive, being applicable to large as well as to small displacements.

The following proposition is new:—

Proposition IV.—The centres of the orbits of the particles in a given surface of equal pressure stand at a higher level than the same particles do when the liquid is still, by a height which is a third proportional to the diameter of the rolling circle and the length of the tracing arm (or radius of the orbits of the particles), and which is equal to the height due to the velocity of revolution of the particles.

Corollaries.—The mechanical energy of a wave is half actual and half potential; half being due to motion and half to elevation.

The crests of the waves rise higher above the level of still water than their hollows fall below it; and the difference between the elevation of the crest and the depression of the hollow is double of the quantity mentioned in Proposition IV.

The hydrostatic pressure at each individual particle during the wave-motion is the same as if the liquid were still.

Friction between a Wave and a Wave-shaped Solid.

In an appendix to the paper is given the investigation of the problem, to find approximately the amount of the pressure required to overcome the friction between a trochoidal wave-surface, and a wave-shaped solid in contact with

it. The application of the result of this investigation to the resistance of ships was explained in a paper read to the British Association in 1861, and published in various engineering journals in October of that year. The following is the most convenient of the formulæ arrived at:—Let w be the heaviness of the liquid; f, the coefficient of friction; g, gravity; v, the velocity of advance of the solid; L, its length, being that of a wave; z, the breadth of the surface of contact of the solid and liquid; B, the greatest angle of obliquity of that surface to the direction of advance of the solid; P, the force required to overcome the friction; then

$$P = \frac{f\,w\,v^2}{2g} L\,z\,(1 + 4 \sin.^2 B + \sin.^4 B.$$

In ordinary cases, the value of f for water sliding over painted iron is ·0036. The quantity $L\,z$ $(1 + 4 \sin^2 B + \sin^4 B)$ is what has been called the "augmented surface." In practice $\sin^4 B$ may in general be neglected, as being so small as to be unimportant.

ATLANTIC TELEGRAPH.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

SIR,—On receiving my monthly part of the MECHANICS' MAGAZINE, I perceived in the "Engineering Summary" of September 12th, in a notice respecting the late sounding cruize of H.M.S. "Porcupine," the following remarks:—"The 'Porcupine' has returned, and a fragment of a side wind report has appeared in the *Times*. This report, which will be found in another column, says: &c., &c.—This is an absurd statement, and rests, we believe, upon no better or more solid opinion than that of an officer, who, notwithstanding that by lecturing and otherwise he had prejudged the case, and shown himself a partisan of the Arctic or North Atlantic scheme, before the Admiralty had complied with the request of the original Atlantic Telegraph Company, was yet permitted to accompany the expedition, &c."

If I be the officer alluded to, I must, in justice, ask you to insert a few words respecting them. Fortunately, the "sidewind" report in the *Times* bears internal evidence of its not being written by any officer of the ship, but it may be satisfactory to state that neither directly or indirectly did the paragraph alluded to proceed from me; as you may be aware that officers on full pay are not allowed to communicate to the newspapers the movements or proceedings of any of H.M. ships, and although an erroneous report (as the one quoted partially is) may appear, the same order prevents an officer correcting that report. Neither am I answerable for the opinions contained therein. Your article would lead a person to believe that I had been about lecturing as a partisan of the proposed North Atlantic Telegraph Route, whereas (at the request of some friends) I have delivered but *one* lecture, and that but once, on the subject of "Ocean Telegraphy," and in that lecture gave no *electrical* opinion (if I may so call it) on either line of telegraph, but studiously avoided doing so; I merely gave my own opinion, *as a seaman*, on the best form of cable for ocean telegraphy in respect to coiling on board ship and paying out safely, *allowing the electrical conditions are perfect*, and made use of the words "sailor's cable," and on which I conceive I can give an opinion. As to being "permitted to accompany the expedition," I was simply ordered—and obeyed. And now, Sir, if not trespassing too much on your space, I will make a few remarks on the subject of telegraphic communication with America, and also answer one or two observations of Mr. Saward's on the published extract of my lecture, and which I did not see till so long after they were published that I did not consider them worth answering. I regret one error I fell into (on the information of one who should have known better); it was that the American company, represented by Mr. Cyrus Field, had received £70,000 for permission to land the cable at Newfoundland, whereas it was £75,000, in shares, &c.; had I said they were to receive great advantages, I should have been correct.

I think that any impartial person will perceive that the case of Mr. C. Field obtaining the concession from the Newfoundland government for the sole right to land a cable on their shores, is somewhat different from that of Colonel Shaffner and the Danish lands. In the former there is no want of money, enterprise, or commercial interest to prevent England carrying a cable to her colony, and thence (by mutual company) to the United States, but all those elements are wanting in Denmark. There was no doubt of the practicability of landing a cable in Ireland or Newfoundland, but that had to be proved in the Northern Route, and involved great preliminary expenses (which might all be sunk), and which expense the promoters of that route have already incurred, so that I do not think Mr. Saward is just in his comparison, although I by no means advocate that such concessions are good.

There is no doubt but that *the* great argument in favour of the Northern Route is the short submarine sections (although I have never seen those rightly stated in print); if they be no object, why not carry the cable at once to New York? Mr. Thomas Allan proposes longer lengths than from Ireland to Newfoundland, but electricians are not united in opinion. Some say that the retardation or inductive action increases in proportion to the square of the distance (and the experiments of Professor Hughes on the Red Sea cable would warrant us in believing that it is so). If that be true, would they not prefer the short sections? There can be no doubt that the risk, damage, &c., is considerably less in the short lengths, and no one will question that in case of loss it is better to lose a part than the whole. There is also a wide difference of opinion in electricians even as to the number of words that can be transmitted by the direct route: eight to sixteen per minute is wide, but even granting twelve (the mean), I may be permitted to doubt that it will ever transmit that number. There was such a vast difference between the promise and performance of the last cable, that, without prejudging the case at all, I may doubt if their expectations will ever be realized—it remains to be proved, and if another cable be laid, I shall be glad to know they can get an average of six words a minute (after it has been in working order a year), aad as many more as they can.

A few words with regard to the nature of the cable most advisable for an ocean telegraph, on which point I do think I may venture to offer an opinion. I have consulted several brother seamen on the subject, and they all concur in the reasonableness of a moderately light one as being that least liable to damage, and best adapted for stowing and paying out. There are several objections to iron-covered cables, which I submit:—1st. Their enormous weight, when placed on board a ship, deepens her to danger, and, as in the "Agamemnon," not only is the cable in danger, but the ship and the lives therein; and it is equally bad when it is paid out,—coals and provisions expended, the ship becomes like a haystack on the water, and a gale of wind and a lee shore would again risk cable, ship, and lives.—2nd. All iron-covered cables require breaks to check them in running out, or, if allowed to run, will take so much per-centage of slack as to be of importance, and in the case of the direct route to Newfoundland, I fully believe that a slack of 10 per cent., with a light cable, will be quite sufficient, thus saving upwards of 10 per cent. and nearly 200 miles of cable—making the entire cable length 1,800 instead of 2,000 miles.—3rd. The probability of injury by superincumbent weight to the heavy cable. I paid a visit to both the "Agamemnon" and "Niagara," and on board the latter witnessed the coiling of the cable, and it then struck me that the lowest sheave of the coil must be very liable to injury by the weight above it, especially if from the motion of the ship the coil ever moved.*—4th. A cable covered spirally with iron is liable to kink, and although it may not kink in paying out, it is quite possible it may do so when slack and under water. Some time since I saw in the papers that another cable was *submitted* to be laid between Ireland and Newfoundland by Messrs. Glass, Elliott & Co., which they proposed covering with coated strands of iron, and that "water tanks will be provided on board ship," for it to remain in. This plan appears to me only to add to the weight, already too great for the ship. The question whether the outer covering of iron wire is a source of strength or weakness may well be argued, and I believe myself it does not add to the strength—*ergo*, it is a source of weakness. I grant that on shore, with a steady purchase, it may prove very strong, and bear an enormous strain, but the conditions are very much altered when paid out from a ship, and the cable having been subjected to the break, and passing over wheels of small diameter, after leaving which it could not bear the strain it formerly did. It is all very well to say its weight is so much in the air and only so much in the water, but let there be a hitch in paying out, a kink, or a heavy send of the ship in a seaway, and all those calculations are useless. As to the iron wires being a protection to the cable when submerged, I do not think it is. Abrasion, I do not believe in in the ocean depths, and as a protection from insects it can be none, as you have only to bend a piece of an iron-covered cable and you will immediately perceive the strands will open quite sufficiently to allow insects to get to the gutta-percha within. The arguments in favour of a light cable are simply—its adaptability for stowage on board a ship without danger of deepening her too much, thus lessening the risk to cable, ship, and lives—the facility with which it can be handled and paid out without check or break, and, if properly constructed, is not so liable to kink as the iron-covered ones. I have seen three cables that I consider well suited for laying in the deep ocean, but of their electrical properties (as I said before) I give no opinion; indeed, I have been told that one is quite inadmissable, and I also beg to remark that I have not seen all (during a short visit to the International Exhibition I searched for them, and could find but few, and those scattered in various parts of the building, and I think it a great pity that the various inventions of telegraphic cables were not placed together). The three I allude to are Mr. T. Allan's, Mr. Hearder's, and Mr. Seimens's, and I perfectly believe that the chances of laying one of those in safety, and uninjured, would be considerably greater than any iron-covered ones, and I can only hope that if the directors of the old company determine to lay another cable they will hesitate to use a heavy iron-covered cable; at all events, that they will consult those who have to stow it in (and pay it out of) a ship; in fact in everything connected with the sailoring part of the business, before they commit themselves to one form of cable or another. As far as any personal feeling in the route of a Transatlantic cable (which would be of little consequence one way or another) I have none. The arguments in favour of the Northern Route are common, many others believe it is the best. Its practicability is, I believe, set at rest (at least as far as Greenland, to which point I have examined it myself), and the strongest argument that Mr. Saward can bring against it is that it would not do to have it under the influence or in the hands or lands of so weak a nation as Denmark. If that relate to the safety of the cable, I can assure him I could much more easily pick up the bight of his cable off the coast of Ireland or Newfoundland, than one on any of the coasts to which it would be taken on the Northern Route. Most pleased shall I be to see another "direct" cable laid, and I sincerely hope it may succeed, but without it does to the extent of the expectations of the electricians, I shall still hope to see one laid on the Northern Route; there is room and requirements for both, and more, without rivalry.

In the event of the cable being laid, and the proceedings of the cable from its cradle to its grave, and its working afterwards, be published by authority for the information of the public, I trust that at least we may rely on what we read, for it is very unsatisfactory to be enthusiastic on hearing that the Queen's message is delivered in so many minutes, and that "the directors are on their way to open the cable to the public," and find out afterwards that the former took many hours, and the latter did not open at all, and yet no one to blame or to be made answerable for putting forth such statements. I believe, sir, that such acts as this—a want of straightforward truthful statements, is a greater bar to the progress of a second attempt than anything I or others can write against it.

I am, Sir,
Yours obediently,
J. E. DAVIS, R.N.

* I have lately sent Sir C. Bright a plan for coiling cables, on flying platforms, to avoid such injury, and which, if worth his attention, he can use for the direct or any other line of ocean telegraph he pleases.

FLUID RESISTANCE.

SIR,—I have read from week to week the discussion going on in your paper respecting the various forms of water-line for a ship's bow—the convex, the hollow or wave, and the straight—each having an advocate in one or other of your correspondents, who endeavours to prove his own view to be correct. This subject among naval architects is well known

to be a much-vexed question, and one in which there are many apparent anomalies; and instances can, I have no doubt, be shown, as is stated by your correspondent "Nauticus," that filling the hollow in a vessel's bow has increased her sailing qualities, while it is a known fact that many of our fastest vessels, as at present constructed, particularly for smooth water, have hollow horizontal lines forward. Again, it is a law in mechanics, that lengthening or extending a wedge increases its penetrating force; and it might be supposed from this, when applied to naval construction, that lengthening the water-lines of a ship's bow would necessarily diminish resistance and increase her speed; but this is not always so, unless judiciously performed. I have before me the model of an old-fashioned Baltimore clipper, with a full round bow (bought many years ago by the late Earl of Wilton, I believe, for her fast-sailing qualities as a yacht) in which this was done. She was brought to England and lengthened some feet by the bow, and her sailing qualities were found to be gone. This may appear singular, but may be explained without violating any mechanical principle. The "America" schooner-yacht, on the other hand—an improvement on the old Baltimore clippers, and famous for her speed—has fine hollow water-lines and a sharp tapering bow; but again, the yacht "Arrow," built many years ago with a full bow, very much like the Baltimore clipper above referred to, I have seen sail and hold her own well with, and very nearly beat, such yachts as the "Musquito," with a sharp hollow bow, and noted for great speed.

From this it is evident that, although the form of the horizontal or water lines doubtless greatly influence the speed of a vessel, there must yet be some other influence at work to produce such apparently contradictory results. Such an influence is to be found in the formation of the vertical longitudinal sections of the bow, known to naval constructors as the bow-lines, and considered by some only of use as means of keeping the bow fair.

When, however, it is remembered that water presses equally on all sides, and, practically speaking, is a fluid of equal density, at least for the depth at which a ship would float, it is evident that its particles rise and fall with the least disturbance, and not only take a horizontal direction past the ship, as is the case with any sensibly lighter floating body, but also a vertical direction under the bottom, and I have no doubt also pass off along lines at any angle between the two; but in designing a vessel of the horizontal sections or water lines, and the vertical sections or bow lines are made as fine as the service for which the vessel is intended will admit, the form of any diagonal lines between the two will follow.

The form of the bow lines was evidently considered in the construction of the old Baltimore clipper, and good speed was attained, although with a full load water line. When lengthened by the bow, the horizontal resistance was lessened, but not so much as the vertical resistance was increased, and consequently the loss of speed. In the "America" both the vertical and horizontal lines are carefully formed, and consequently a very fast vessel is the result. In the vessel in which the hollow in the bow was filled and the speed increased, as instanced by your correspondent "Nauticus," the effect would be not only to increase the stability and canvas-carrying power, but also to lengthen the bow lines, diminishing the vertical resistance, and so increasing speed.

In the case of the "Pysche," referred to by your correspondent, Mr. Moy, it is evident from the heaping up the water before her bows, not that probably the horizontal lines are so very defective, as that the vertical lines are so full as not to admit of a due proportion of the particles of water passing under the ships' bottom. In illustration of this, let anyone observe a Thames sailing lighter, with a square projecting bow, the water line of which is nearly as broad immediately forward as midships, and perfectly angular, many of which, with a good wind, I have seen sail as fast as craft with a very respectable-looking water line, and certainly heap little or no water at the bows.

This is in consequence of the slanting bow diminishing the vertical resistance, and allowing the water to pass, in a great measure under the bottom. The heaping of water at a vessel's bow, is one great evidence that the form of the vertical lines have not been properly attended to, and shows an undue amount of resistance. A vessel with moderately-fine vertical lines never does this. With regard, however, to the best form of water line to be adopted—I am speaking only of the bow—even when the vertical lines are made as fine as is consistent, I would remark that it must depend on the service for which the vessel is intended, but of course this must be a matter of opinion and experience. Still an opinion with a reason, is better than one without. For sailing vessels and sea-going steamers, I should prefer the load water line to be slightly round or convex, because it both increases the canvas-carrying power, and adds to the length of the vertical bow lines; the fine bow lines will naturally give hollow water lines below. The convex water line also admits of the centre of gravity of displacement being kept slightly before the centre of the load water line, and of a proper adjustment of the fore and after bodies of the ship, for I cannot agree with Mr. Moy, when he says a vessel is none the worse for having the buoyancy brought aft, for unless the bodies are properly adjusted, she will pitch in a seaway, and will lose far more from this than she gains (even allowing it to be a gain) by a hollow load line. For a steam vessel, however, constructed only for smooth water, a slightly-hollow load line may, in long vessels, be used with advantage; but I certainly do not think the form adapted for a seaway. I will give an instance of this. A friend of mine, in crossing, a year or two ago, from Dieppe to Newhaven, in the "Orleans" (one of the boats referred to by Mr. Moy as of great speed), encountered in her passage rather a strong wind and a moderate sea, but nothing unusual for the Channel in autumn, when the boat was found to lift but very little to the seas, and she was obliged to put out some of her fires, and work across with but one engine, for fear of driving her bows under, the water being at one time nearly knee-deep on deck, forward.

Here is an instance when a fuller bow would have made a faster ship. Had she not have been so sharp in the bows the engines might both have been worked, and the passage made in less time.

I have brought forward some of these examples to endeavour to show that similar effects may be produced by apparently most opposite causes, and that the good qualities of a vessel cannot be judged of by the excellence of any one particular feature, but must be estimated as a whole. The effect of a fine horizontal line is neutralized if the vertical resistance be great, or if the fore and aft bodies be not properly adjusted, and the ship pitches in a seaway. No ship can be said to be properly designed that has any one feature, however good in itself, too prominently developed at the expense of some other good quality. The nearest approach to perfection in naval architecture is attained in that ship in which all are carefully considered, and, by a species of compromise, made to give place to each other. In the above remarks, the bow has only been treated of, but attention to the form of the after body is of nearly equal importance.

I am, Sir, your obedient servant,

John C. Martin.

Barnes, S.W., Sept. 29, 1862.

GLACIER PHENOMENA.

Sir,—In discussing a theory propounded by Professor Tyndall (but originating, it is said, with another learned gentleman) a subsequent correspondent has started a difficulty that appears to me wholly imaginary. He objects to the idea of the greater extent of glaciers in former days having been due to greater elevation of surface, that such elevation would require to be fully three-quarters of a mile, *i.e.*, about 4,000 feet. But what of that? There are still existent mountains that are not merely 4 but 14,000 feet higher than the average of Alpine peaks (ranging from 11 to 15,000 feet), so there can be nothing at all unreasonable in the hypothesis that the whole area of modern Switzerland was formerly occupied by a plateau of 16 or even 20,000 feet elevation, the space comprised between the Jura and the Alps affording ample base for such a plateau.

The more assailable point of the Professor's speculations would appear to be the assertion that the present valleys were not merely deepened and increased, but positively originated by the action of glaciers. If such a plateau as we have supposed were not originally intersected by chasms and ravines, *i.e.*, if it were a level and unbroken surface, the effect of glaciers moving over it would merely be to wear it down equally, horizontally, still level and unbroken. It is only where a hollow or a cleft already existed that the abrading action, whether of water or of ice, would tend to be greater at one place than at another, and thus to increase the inequality of surface.

With this modification, however, the Professor's theory might stand. If he concede that the valleys originated in rents of the surface due to the force of elevation, there can be little doubt of general assent to the further proposition that they have been enlarged to their present dimensions more by the action of ice than of water.

But there is another point, on which it is impossible to justify the Professor, and which appears to have been dimly perceived by your correspondent, though he does not put it in words, viz:—that the phenomena of Switzerland should not be considered alone, but rather in connection with neighbouring countries. Were Switzerland the only spot presenting signs of much greater glacial action in former epochs, it might fairly be explained by the hypothesis of local elevation. As, however, such signs are common to the greater part of Europe, your correspondent is quite correct in hinting (for he does not *say* it), that it behoves us to seek some more general cause; and the hypothesis he throws out regarding the Gulf stream is deserving of scientific consideration. It is undoubted that the milder temperature of Western Europe is mainly owing to this current: and, further, that the course of the current is entirely regulated by the conformation of the land forming the coasts and bottom of the Atlantic Ocean. We also know positively that this conformation has varied at sundry geological epochs, and it is quite conceivable that at the glacial period it was so different from the present, that the heated waters of the Western tropics were *not* then, as they are now, reflected round to the shores of Europe. But it is not conceivable to anyone acquainted with the topography of Central America, that the vast barrier of the Andes should have been "broken down" and re-erected as he imagined. From the extreme north of the Rocky Mountains to the south of Peru (if not farther) this range is obviously the result of one vast contemporaneous crack or fissure in the earth's crust, and all subsidence or elevation that has since occurred has been on a comparatively small scale. It would, therefore, be necessary to investigate geologically the relative dates of the elevation of the Andes and the glacial period in Europe. If the former should prove to be antecedent to the latter, your correspondent's idea regarding the course of the Gulf stream would be untenable; it would still, however, remain possible that the current should at that time have continued its course due north, along the coast of North America to the Polar basin, where signs are rife of a former temperature more genial than the present; or it is further possible that the outline of land and water was then so different that no Gulf stream existed.

If it were allowable to throw out fanciful conjectures, I would refer to the ancient traditions of Atlantis, &c., as indicating that an enormous subsidence may have taken place in the Atlantic within a recent (geological) period; so that modern Europe was previously the centre of a vast continent, which is well known to increase the rigour of climate. At any rate, it would be worth while for the professors studying the glacial period, to extend their views beyond Switzeland; and this hint regarding the Gulf stream may be worth, of grave consideration

Your obedient servant,

Viator.

SMOOTH-BORED AND RIFLED CANNON.

Sir,—Permit me to call attention to the report in the *Times* of experiments with the Horsfall and Whitworth guns, where it is said that a shot from Armstrong's rifled gun retains its initial velocity up to 2,500 yards of flight, and this extraordinary assertion is again repeated in a leading article on the subject in the *Times* of the 18th inst. As this must surely be a mistake, and as the public who pay for these wonderful guns may be misled thereby, I venture to show that such a result is an impossibility.

The statement is, that the velocity of a shot when leaving Armstrong's gun is 1,150 feet per second, and that it retains this rate of motion until a range of 2,000 or 2,500 yards is attained. Now if this be true, the shot at the end of 2,500 yards' flight, possessing undiminished speed, must have the same momentum as it had the moment of leaving the gun, and as this momentum carried it 2,500 yards, and the shot being as lively as ever at the end of this flight, it necessarily follows, the projectile can go another 2,500 yards under the same condition, nay, any number of spaces of an equal length, until gravity brings it to the ground. But, as a matter of fact, is there any proof that a shot from Armstrong's guns maintains its initial velocity for 2,500 yards? I believe there is none.

SIR CHARLES BRIGHT'S IMPROVEMENTS IN ELECTRIC TELEGRAPHS.—(*See page* 221.)

FIG. 1.

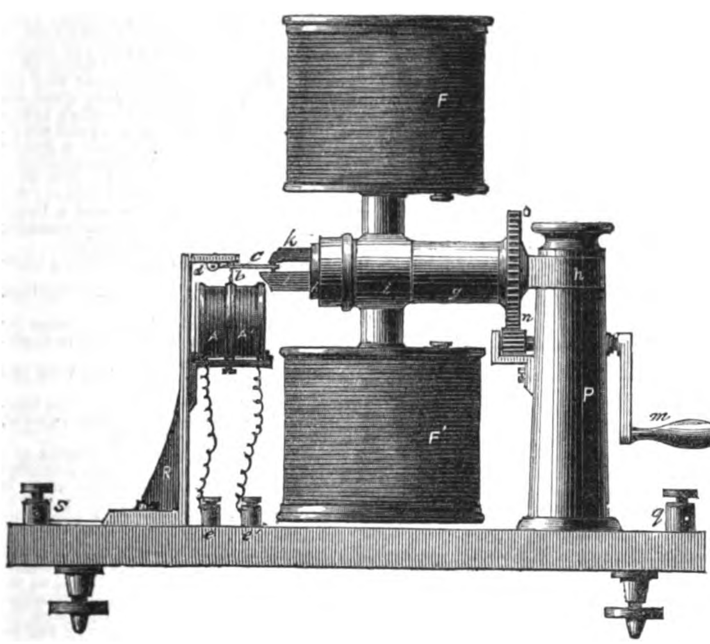

FIG. 2.

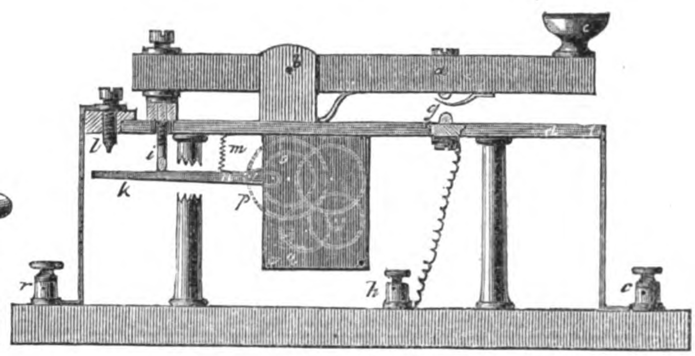

As a matter of theory, it is impossible that such is the case; for whatever is the size or shape of a shot, or the quantity of powder with which it is propelled, its velocity on leaving the gun is maximum speed, and it goes slower and slower to the end of its flight. There is no living power within it, as in a rocket, to force it onward. The impact of the powder on the shot ceases the moment it leaves the gun, and from this moment the resistance of the air opposes the onward progress of the shot; and how great a retardation this effects has been shown by Robins in his admirable treatise on gunnery, who there states that a leaden ball of three-quarters of an inch in diameter, issuing from the muzzle of a gun with the velocity of 1,670 ft. per second, loses 125 ft. per second of its speed in passing through only 50 ft. of air.

What, then, must be the loss of velocity of a shot four inches in diameter, and passing through 6,000 feet (2,000 yards) of air? It is enormous, as is proved by the difference between the initial velocity of a round shot, say 1,600 feet per second, and its final velocity, often only 450 feet per second. I think, therefore, it is clear that the resistance offered by the atmosphere to the flight of a shot at high velocities through it is so great as to produce a very large amount of retardation of the ball's speed, even at short ranges; and I repeat, that it is absolutely impossible, whatever may be the size or shape of Sir Wm. Armstrong's shot, for it to continue a flight of 2,500 yards at the same speed at which it left the gun's mouth.

And I think it will ever be found that atmospheric resistance will in long ranges so retard shot, that armoured ships will be invulnerable at ranges exceeding 400 or 500 yards, except to shot of more than 300 lb weight. Whitworth's gun appears to have done well, but as yet there is no proof that it will penetrate a five-inch plate of first-rate quality at any considerable range. The best experiments with it at Shoeburyness are of no value, the plates being bad; and from the peculiar construction of Whitworth's shot, I fear it would jam in the gun when this became heated by repeated firing. I have seen numerous experiments with this cannon, but the firing ceased before the gun had time to become hot. The importance of large guns is daily becoming proved, and I will again revert to the subject, showing how such guns can be made of less weight and handier construction than they are at present.

MARTYN ROBERTS.

Pendarren House, near Crickhowell.

THE WAVE LINE.

SIR,—Will you allow me a short space, to contradict the statement of your correspondent "Nauticus," about the yacht "America." He says that her load line has scarcely more concavity than would be sufficient to break in the straight line of the stem to the convex line of her bow without an angle at the "head ends." Just as if the *load water line* is to be a wave line. Perhaps "Nauticus" would like the deck line to be a wave line. The bow and stem of the "America" are both perfect wave bodies, and if "Nauticus" will try about 6 ft. below the load line, he will find as beautiful a wave of translation and a wave of oscillation as possibly can be constructed.

"Nauticus" would alter his opinion about Mr. Scott Russell's wave line if he only knew how to *apply it*.—Your's, very obediently,

J. QUART.

7, Amersham-vale, New-cross.

Gossip.

Two of the 100-pounder Armstrong guns for the naval service were subjected to proof on the 2nd inst., at the Royal Arsenal practice range, and both guns burst with a charge of 27½ lb. of powder, the inner tubes being completely rent directly behind the trunnions. Another 100-pounder, recently tested, also burst in the centre of the chace transversely, immediately across the barrel. These disasters are said by some practical men to be connected with the system of piece-work adopted in the gun factories, and it is stated that the work is in consequence hurried over. Sir William was never yet without an excuse for the failure of his guns. The excuse now is that the men have scamped their work. Two 200-pounder muzzle-loading guns, manufactured at Sir W. Armstrong's factory, Elswick, arrived at the Royal Arsenal on the 2nd to be tested at the practice range, and a 300-pounder on the same principle.

The petroleum controversy in Liverpool has been diversified by an invention which, it is stated, will both prevent the oil from exploding and from giving out a nauseous odour. The invention is simply a metal cask, perfectly air-tight, and therefore likely to answer the double purpose above stated. It has obtained the approval of those interested in the matter.

The Madrid journals mention the construction of a Spanish iron-clad, which they style a marvel. According to them, this monster of the deep surpasses anything as yet possessed of this kind by England or France; and they boast that early next year the Spanish flag will float over the best iron-plated ship yet launched.

A prospectus has been issued of the Universal Club and Permanent Exposition Company, with a capital of £100,000 in shares of £5 each. The proposal is to establish a permanent mart in London for the exhibition of samples, patterns, and models, and to secure for the purpose certain premises in Cannon-street which are considered to be peculiarly eligible. Exhibitors paying an annual rent for space are to be afforded also many of the usual services of a club, and an advantage in terms is to be given according to priority of application. The first 1,000 subscribers are to pay £20 per annum, the second £25, and all others £30. Extensive promises of support are stated to have been received from French and other manufacturers. The locality of Canon-street, as a great centre of the railway traffic to the city, seems the best that could be selected for such an undertaking.

Mr. H. Redsull, of Deal, has invented a submarine gun and port, a plan of which has been submitted to the Lords Commissioners of the Admiralty. The chief feature of the invention is to allow the barrel of a gun to be forced through the port, in order that a shot may be discharged from it to pierce vessels below the water line and iron coating when in close action, without taking in water at the port. It is calculated that a vessel fitted with this invention will be able to sink the Warrior or Monitor in a few seconds. The expense of fitting vessels will be very moderate, as it is contrived that almost any piece of ordnance may be used at the submarine port.

An interesting experiment was recently made on the Seine, opposite to the Palace of St. Cloud. A bridge was thrown across the river, in its widest part, within the short space of 20 minutes. This operation, which was formerly considered to be one of the most difficult in the presence of an enemy, is now accomplished with comparative facility. The bridge thrown over the Seine within so short a time on Thursday was sufficiently solid to permit infantry, cavalry, and artillery to cross the river.

T. M. says not one of the "Wave-line" disputants in his letters makes any difference between sailing vessels *on a wind* and the same running before it. When a vessel is on a wind the lee bow is pressing against the water sideways, as it were, whilst the weather bow may be said to be retreating from the water. In running before the wind the pressure is the same on both bows. In a steamer, also, the pressure on both bows is equal in 999 cases out of 1,000. May not this have something to do with the merits and demerits of the wave-line theory? If so, we may say to these gentlemen, in the words of the chameleon:—

"You both are right and both are wrong."

I think the anathematizing captain must have been smarting under a series of head winds, and had been on one tack for a length of time.

A few days since an experimental trial was made at Spithead of an invention, by Mr. H. D. P. Cunningham, R.N., for protecting the screw-propeller of men-of-war steamers from being fouled by floating wreckage or gear of any kind liable to be drawn by the current towards the screw. The trial was made under the direction of Commander Miller of,

her Majesty's ship "Asia," and other officials. The screw and protector invented by Mr. Cunningham were fitted to a small schooner-yacht, the property of the inventor. The yacht was towed astern of the "Swinger" gunboat, the screw of the schooner being kept working. A quantity of loose spars, rope, and other gear was then thrown overboard from the "Swinger," and the yacht so managed as to place the screw and apparatus under every possible disadvantage, with the view of fully testing the system. Every endeavour, however, to foul the screw with loose gear failed. The apparatus is most simple, consisting of iron bars projecting from the sternpost and netting, the whole of which, when not in use, lies close to the ship's quarter. The screw-protector will form a valuable auxiliary to the screw under circumstances of difficulty, as regards wreckage and floating masses likely to disable the propeller.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

The Abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following Table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved, and combined with all the advantages of a division into classes. It should be understood that these abridgements are prepared exclusively for this Magazine from official copies supplied by the Government, and are therefore the property of the Proprietors of this Magazine. Other Papers are hereby warned not to produce them without an acknowledgement:—

Steam Engines, 726.
Boilers and Furnaces, 710.
Roads and Vehicles, 694, 709, 712, 719.
Ships and Boats, 695, 730, 732.
Cultivation of the Soil, 707, 718, 736.
Food and Beverages, 724.
Fibrous Fabrics, 725, 739, 749, 750, 752, 758.
Buildings and Building Materials, 702, 717, 720, 751.
Lighting, Heating, and Ventilation, 692, 699, 705, 715, 731, 744.
Furniture and Apparel, 693, 696, 703, 711, 713, 716, 723, 728, 729, 737, 740, 741, 753, 757.

691. M. Henry. *Improvements in stuffing boxes.* (A communication.) Dated March 13, 1862.

This relates to a previous patent, dated Nov. 22, 1861, No. 2,940, and which mainly consisted in the use of a movable box or tube, or a tubular piece, or a block, or piece having a passage bored or formed through it, such box, tube, piece, or block surrounding the piston-rod or other article to which it was to be applied, and partaking of the play or wabbling motion thereof, and the box, tube, or piece (which might be made in one or more pieces), was called in the said specification a packing or surrounding appliance. Now the chief object of the present invention is to render the aforesaid arrangement more effective, especially when applied to engines working at high and continuous pressures. For this purpose a stuffing box or other mechanical contrivance for retaining packing is connected or attached to, or is formed on or with the surrounding or packing appliance, so that the stuffing-box, &c., together with the hempen or other flexible packing with which it is furnished, or which it retains, shall move with, or partake of, the motion of the surrounding or packing appliance. *Patent completed.*

692. R. A. Brooman. *Improvements in apparatus for measuring and regulating the flow and pressure of gas, parts of which are applicable to hydraulic receivers and to steam generators.* (A communication.) Dated March 13, 1862.

693. G. Calvert. *Improvements in castors.* Dated March 13, 1862.

This invention relates to spherical castors, and consists in fitting in the socket an inverted cup, held by a stump or bar, and in placing above the upper end thereof a spring. Grips or claws are continued from the bottom of the socket to prevent the sphere from getting away; or instead of claws, a cup may be used. The sphere revolves in contact with the edges of the inverted cup, which is free to revolve round the stump; or the stump and cup may be fixed together, and then the stump and cup may move in the socket as one piece. *Patent abandoned.*

694. S. K. Thompson. *Improvements in railway apparatuses for communicating between guard and driver, and for coupling and uncoupling the carriages, parts of which apparatuses are applicable to connecting pipes and tubes.* Dated March 13, 1862.

This invention, for improvements in apparatuses for communicating between guard and driver, consists of the arrangements hereafter described:—The inventors carry a pipe or tube through every carriage, and form the connections between every two carriages by means of two trumpet-mouthed tubes, pressed into contact with each other by means of coiled or other springs, and free to recede within the tubes in the carriages for a certain distance. Or they form the connection by means of a flexible pipe, by preference of india-rubber; one end of the pipe is fixed to one end of the tube running through the carriage, while the other end is fixed to a bell or other shaped mouth, the lips or edges of which have connected to them guide rods, free to slide in and out of the carriage, and kept extended by coiled or other suitable springs. This flexible spring pipe coupling is applicable to pipes for conveying liquids and fluids generally. When required to increase the intensity of the sound produced by the guard in communicating through the tube with the driver, or *vice versa*, they place a valve near the mouth-piece, and in front of that valve introduce a bell-mouthed curved tube, open outside the carriage, for the purpose of catching the wind and of driving forward the sound made after the valve is opened. For coupling carriages the invention consists, under one modification, of two fixed hooks, and of two movable hooks. One fixed hook and one movable hook are fitted to each carriage to a boss, placed on the end of a bar, capable of being protruded from and drawn towards the carriage. The movable hooks are pinned to the bosses on the bars, and have springs fitted to them to cause them to assume constantly a position parallel to the rails; to each of the bosses a lever is fitted, and also a weight. The coupling is effected by the carriages being brought together, when the spring hooks will become engaged in the fixed hooks. To uncouple, the boss is turned by means of the lever, when two of the hooks on one boss will be turned and freed from one another; a eight is employed for bringing back the hooks into position, when the lever is let go. *Patent abandoned.*

695. J. B. Howell. *Improvements in the manufacture of chains and chain cables.* Dated March 13, 1862.

Here the inventor employs steel or iron, or a combination of steel and iron, rolled of any required thickness and breadth, with one face concave, and the other convex in transverse section. The metal so rolled he forms into links of such shape as may be required, by coiling the strips of metal around a core or centre, which corresponds with the interior of the link to be made, and towards which the convex surface of the metal is placed. He taps 2, 3, 4, or more, coils continuously, the one in the other, the convex surface bedding into the corresponding concave surface. For this purpose he heats the metal bar or strip in a suitable furnace, to a welding heat, and while so heated, winds it up on the core or centre before-named, and welds it throughout as it is being coiled up, pressure being exerted by a suitable bar, or part at the point of contact and welding, to insure the uniting of the metal. To further insure and improve the main of the coils of the link, he causes a current or blast of air to impinge on the point of contact and union or welding of the metal, which has the effect of increasing the heat of the iron, and removing any oxide or scale formed on the uniting surfaces. *Patent abandoned.*

696. H. Fletcher. *Improvements in neck-ties, scarfs, cravats, and collars.* Dated March 13, 1862.

This consists in attaching, and combining permanently, a collar to a neck-tie or cravat, or scarf, instead of such articles being distinct and separate as at present practised, and the invention applies to washing ties, cravats, or scarfs, so that the collar and tie, cravat, or scarf, can be washed together as one article, instead of separately, if necessary. By this invention, the collar requires no band, but is simply sewn to the material which forms the tie, &c. *Patent abandoned.*

697. W. E. Newton. *An improvement in armour plates for vessels of war.* (A communication.) Dated March 13, 1862.

This relates both to armour plates applied on the outside of wooden hulls, and to iron plates attached directly to the frame of the vessel, whether such frame be constructed of timber or iron. The invention consists in a mode of fitting together and combining the marginal portions of the armour plates, whereby the plates will be so locked as to hold each other both in a direction lengthwise of the vessel to which they are applied, and also in a vertical direction, and thereby assist in holding each other to the sides or frames of the vessel, and in strengthening the vessel. The necessity of using plates of very large size will also be obviated. *Patent completed.*

698. E. Bolton. *Improved apparatus for transferring liquid matters from one vessel to another.* Dated March 13, 1862.

In adapting this invention to the use of soap boilers, who require to transfer the saponaceous mixture while in a liquid state from one pan to another, or from the pan to the soap frames, or from the pan to a cistern or receiver, the inventor fits through a socket, in the centre of the pan, a tube which passes down to the surface of the soap, or other manufactured liquid. This tube, which is closed at the top and opens into the pan, has a branch, or branches, either metal or flexible, leading off to the soap frames or other vessels in the same room or rooms above or below. The pendent portion of the tube is fitted with a steam jacket, and so also is the branch tube or branches leading from the upper part to the soap frames or other receiver. *Patent abandoned.*

699. R. Schomburg. *Improvements in purifying illuminating gas.* Dated March 13, 1862.

Here in order to separate from gas the sulphide of carbon with which it is commonly contaminated, and which when the gas is burned produces sulphurous acid, which is destructive to furniture and otherwise injurious, the inventor causes the gas to come in contact with hydro-carbon or other oil, or a solution of fat, soap, or resin; these substances have the property of absorbing the sulphide of carbon. The purification may be effected either at the gas works, or by each consumer, and he prefers to use for the purpose a disc of perforated metal kept constantly revolving; the lower part of this disc dips into the oil or other liquid, and brings up as it revolves a film of the material, portions of the film closing the perforations in the disc. The gas is caused to come in contact with the disc, and pass through the perforations therein, so that the liquid may be able to act on every portion of the gas. When the purification is effected separately by each consumer, they combine the purifying apparatus with the gas meter, and cause the perforated disc to be driven thereby. When the liquid becomes saturated with sulphide of carbon, the latter may be separated and obtained by a process of distillation, leaving the oil or liquid in a state to be again used. *Patent abandoned.*

700. J. Kent. *Improvements in cleansing and bleaching.* (A communication.) Dated March 13, 1862.

This consists in subjecting cotton and other vegetable fibre, whether in the form of yarn or thread, or made up into fabrics or otherwise, to the following process: Lime and soda are mixed (in the proportion of about 8 lbs. of carbonate of soda to 1 lb. of lime) with water, and allowed to stand to settle, when the clear liquor is drawn off or separated from the solid matters. It is found that the strength of the liquor when used should mark about one and a-half to two and a-half degrees of Twaddle's hydrometer, a strength of one and a-half degrees is found sufficient for fine light goods, and for heavier goods a greater strength. The yarn, thread, or fabric, or other preparation of vegetable fibres, is steeped in this liquor for from 30 to 50 minutes, more or less, as the case may require; fine goods require about 30 minutes, and stouter ones a longer time in proportion. The process of cleansing and bleaching is then finished in the usual way.—*Patent completed.*

701. A. Quinard. *A machine for manufacturing horse-shoe nails.* Dated March 14, 1862.

This invention is not described apart from the drawings. *Patent completed.*

702. R. Garthwaite. *An improved mode or design for providing extra, superior, or better accomodation in double-tenement houses.* Dated March 14, 1862.

Provisional protection has not been granted for this invention.

703. G. H. Birkbeck. *Improvements in trusses or bandages, and in pessaries to be used therewith when required.* (A communication.) Dated March 14, 1862.

This relates to the arrangement and combination of a jointed and movable pessary, a replacing and graduated relieving apparatus or instrument for keeping the uterus in its place, and intended for the prolapsus utery, and to remedy the displacement of that organ. This instrument is connected to or combined with a double-jointed hypogastric bandage, with a posterior pad or cushion, by a curved supporting arm of swan-neck form which fits the convexity of the pubis, and which can be moved as required to the right or left, in order to adopt itself in the most convenient manner possible to the intravaginal rod which carries the bowl or hollow elastic instrument for supporting the deranged organ. The mode of jointing the intravaginal rod with the curved arm or swan-neck connection allows the rod to move freely round its vertical axis, so as to perform the lateral anterior, posterior, and all the motions intermediate to them; and, lastly, to describe a cercuitous movement. The pads or cushions are jointed to the hypogastric truss, which are capable of being readily fixed and adjusted in any desired position; these pads or cushions are intended to sustain the weight of the abdomen, or to exercise a pressure on the region of the arms, or upon any one or more of such points. *Patent completed.*

704. G. Bennett. *An improvement in the coating and covering of wrought iron, for the purpose of preserving it, and preventing oxidation.* Dated March 14, 1862.

To render the iron fit to receive the coating and covering it must be prepared in the following manner:—The inventor mixes with 10 gallons of cold water 1 lb. of sulphuric acid, in which he places the iron intended to be coated, and lets it remain six hours; he then takes it out, and scours it with sand or emery, washes it well in clear spring water, and then places it in a stove heated to 212 degs. Faht. for ten minutes; it is then fit for the coating. The coating is made as follows:—28 lb. of flint, calcined and ground fine, 14 lb. of borax pulverized; these are calcined together till they are fused; lets them cool, and adds to them 5 lb. of potter's clay; he grinds these ingredients in water together, to the consistency of paint, and coats the iron with this to the thickness of about one-tenth of an inch. When this has become set, which it will be in a dry place in a few minutes, he then proceeds to apply the covering, which must be very carefully dusted over it, before it becomes dry, and which is made of 62 lb. of white glass, 12 lb. of borax, and 10 lb. of soda; he grinds these to a fine powder, and then lets them be vitrified in a crucible. When cool, he grinds this compound in water until very fine, then places in a kiln until quite dry. He then takes of this composition 22 lb., and 8 oz. of soda, mixes them in hot water, submits them to a moderate heat in a stove, and a fine powder will be produced. He sifts this powder evenly over the coating, and then places the iron so covered in a stove at a temperature of 212 deg. Faht. to dry; he then places it in a kiln, such as is used by china manufacturers for fixing enamel. The kiln must be heated to a sufficient degree to fuse the covering; the iron must be gradually heated at the mouth of the kiln, and then placed in the full heat till the covering is fused, when it must be gradually withdrawn to cool. *Patent abandoned.*

705. G. H. Sanborn. *Improvements in gas regulators.* (A communication.) Dated March 14, 1862.

This consists in regulating the pressure of gas between the main or sheel pipes and the burners, to check or reduce the pressure on the remaining burners, when some of the whole number of burners are not being used, and to keep the flow of gas to the burners uniform and steady, and at the most economical amount, whatever number of burners may be in use. *Patent abandoned.*

706. L. Gabler and M. Zingler. *Improvements in manufacturing articles from ivory and bone.* Dated March 14, 1862.

Here the patentees take ivory powder, or bone, and reduce it to a fine powder; this powder they mix up into a dough with a cementing liquid, such as a solution of gelatine or gum ammoniacal; they then press this dough into a mould or form, so as to shape it into the article required. The mould used is arranged so that it may be closed, in order that a considerable pressure may be applied to the dough without causing it to flow out. The joints of the mould, however, are not so tight as to prevent the escape of the water or liquid with which the ivory or bone dust is mixed, one principle object of the pressure being to expel this liquid and the air. The article after a time is removed from the mould, and soon becomes as hard as ivory, which

in other repects it resembles. Colouring matters may be mixed with the dough if desired. *Patent completed.*

707. G. T. BOUSFIELD. *Improvements in machinery for digging and disintegrating the earth for agricultural purposes.* (A communication.) Dated March 14, 1862.

The object here is to dry up soil by rotating tools, which enter and pry off soil in a manner analagous to the operation of a hand-spade or fork. To this end the first part of this invention consists in the combination of a series of rotating digging tools with a carriage frame, by which they are moved forward, and with mechanism, which causes the series of diggers to enter the earth, so as to divide the earth into successive slices, whose sides are perpendicular to the line of progression of the machine, and after penetrating to pay off and raise the slices in a way analogous to the operation of a hand-spade or fork by the continued rotation of the series. The object of the second part is to break the clods effectually after they are raised, and to detach them from the diggers. This part of the invention consists in combining the series of rotating diggers constructed and operated substantially as above set forth, with cleansers which extend between the diggers after they rise from the earth, so that the slices or clods raised by the diggers are operated upon by the said cleanser and are broken. The object of the third part is to enable the diggers to be set to penetrate the earth to different depths as desired, and to carry the diggers above the ground when not in use, and this part consists in combining the carrying wheels with the carriage of the digging machine by cranked axles controlled by a lever and winch, or their equivalent, so that the carriage and diggers can be lowered or raised upon the carrying wheels by operating the said winch. The object of the fourth part of this is to enable the digging mechanism to be operated and propelled in a simple and effectual manner by steam power, so that the machine constitutes a digging locomotive, and this object is effected by combining the steam engine or engines of the locomotive with the diggers, so that the latter may not only dig the earth, but also constitute the drivers, by which the digging locomotive is caused to progress. *Patent completed.*

708. A. J. PATERSON. *Improvements in the construction of electric telegraph cables.* Dated March 14, 1862.

This invention consists in the employment of a flexible or jointed pipe or tube, or series of tubes, within which the insulated conducting wires are placed. The pipes or tubes possess great tensile strength, and may be made watertight by gutta percha, india rubber, tarred hemp, or any suitable material or combination of materials, with or without wire, as circumstances may require. This flexible jointed tubing may be protected from corrosion, when made of metal, by galvanising or by being coated or covered with gutta percha, marine glue, or any other like protecting agents. *Patent completed.*

709. M. A. MUIR, and J. MCILWHAM. *Improvements in railway sleepers and chairs, and in the mode of fixing rails.* Dated March 14, 1862.

The improved sleeper is cast in the form of a disc; there is a central boss which forms a base, from which the chair jaws spring. This part of the sleeper is cast thicker than the other portion, and below it is further strengthened by a transverse rib, which extends across the underside of the boss, and has formed on it a feather, which is directly under the centre of the rail, and which fits a notch in the bar. From the raised central part the surface of the sleeper slopes slightly towards the margin, the rim being curved in an outward direction, somewhat similar to the lower part of a bell. The sleepers when laid upon the ground are connected by transverse tie bars, which extend beyond the centre of the sleeper, and this part of the tie bar is notched to fit the feathered part of the central rib of the sleeper. The tie bar is fastened to the sleeper by a saddle bolt, which passes up through the disc, and is secured thereto either by a nut or split key. The second part of the invention refers to a mode of fixing rails in the chairs. *Patent completed.*

710. W. TURNER. *Improvements in the construction of bakers' ovens, and in the use of furnaces and other apparatus connected therewith, and in the means of appliances employed therein.* Dated March 14, 1862.

Part of this consists in using a square or other suitably shaped oven, having metal doors extending the entire width thereof. These doors are lined or cased with fire-clay, fire lumps, or other suitable material, and are hinged at the top on a straight bar, which extends the whole length of the breastwork of the oven or ovens, the said bar being fixed parallel with the spring of the arch of the oven; the doors being thus hinged their own weight will cause them to fit closer, and thereby the oven will retain the heat better than if the doors were hinged from the sides or bottom thereof. The inventor also uses a furnace and flue, and places the furnace-doors in a parallel or nearly parallel line with the oven doors, and causes the flue to rise from the contrary or opposite corner to that of the furnace, by which arrangement the whole area of the oven or ovens becomes equally heated. The furnace opening on the square side of the oven opposite to that of the flue will afford a greater radiation of heat than would an opening on the angular side of an ordinary oven. *Patent abandoned.*

711. A. COLES and W. COLES. *Improvements in the construction of trusses for cases of hernia.* Dated March 15, 1862.

This refers to a previous patent, dated 5th July, 1821 (No. 4567), and comprises certain improvements, whereby it is not necessary that the trusses should be expressly manufactured for each description of abdominal hernia, as the pads need not be at different angles to the body spring. We cannot give space to the details of the invention. *Patent completed.*

712. W. CLARK. *An improved break for railroad carriages.* (A communication.) Dated March 15, 1862.

This consists in the use of what the patentee terms a tumbling-rod, which is placed longitudinally underneath each carriage, just above its axles, the tumbling-rods of the several axles comprising a train, being connected together and so arranged that they, with their draw bars, may be rotated and also lowered and raised, and by means of suitable gearing, connected with a slide and belt slipper. The above parts are used in connection with two cones, a belt, and two cylinders, one cone and cylinder being placed on an axle of each carriage, and the other cone and cylinder on a lever which is connected to a chain attached to the break bars, all being arranged substantially, as shown, to effect the desired end. *Patent completed.*

713. H. EMANUEL. *An improvement in the manufacture of ornaments for personal wear.* Dated March 15, 1862.

For the purposes of this invention the inventor uses ivory as the body mounting or setting of the article, thus:—the inventor takes the ivory in a piece, and cuts or otherwise forms it into the desired form, and he combines it with metal and with gems (real or artificial), stones, or other articles used as ornaments, by cutting or otherwise forming in the ivory a recess or recesses, or opening or openings, and when required he bores or drills orifices in such recesses or openings, and sets the gem, or stone, or other article, in a rim or setting of gold or other metal, which he attaches by cementing, riveting, or otherwise, into the ivory. *Patent abandoned.*

714. C. N. KOTTULA. *Improvements in the manufacture of combined soaps.* Dated March 15, 1862.

This invention consists in the combination of pearl ash with combined soaps, whether with such combined soaps as result from the combination of a curd with a hydrated soap, according to the invention patented by James Blake and Francis Maxwell (No. 2,016, August 30, 1856), or with such combined soaps as result from the combination of a curd soap with elements producing a hydrated soap, no matter in what manner they may be manipulated, combined, and finished. Or with such combined soaps as result from the combination of any ordinary finished soap with a hydrated soap, or with the elements producing a hydrated soap, mottled or not, and with or without resin. *Patent completed.*

715. G. B. PETTIT. *An improved method of, and apparatus for, heating water and other liquids, applicable also to the evaporation of liquids.* Dated March 15, 1862.

This invention consists in heating water for baths and other purposes, and in evaporating liquids by means of what the patentee terms a "floating fire." The apparatus consists of a double bowl or cup of sheet metal, with a space between the two cups, with tubes establishing communication between the inside of the inner cup and the water in which the apparatus floats, and with a central pipe rising from the bottom of the inner cup above the line of flotation. He inserts a pipe, connected to a gas supply by flexible tube or otherwise, and fitted at its lower end with a burner with radial jets, into this central pipe, and fixes it so that the jets shall not touch the outer cup. He places a cover of mica or other transparent material on the central pipe, and lights the gas jets prior to inserting the burner. Air channels for supplying air for supporting combustion are carried down the outer cup. In some cases he dispenses with the central tube, and forms the burner on or attached to one or other of the cups. According to the size and purpose to which the apparatus is to be applied, so must the number of gas jets be varied. *Patent completed.*

716. J. SMADJA. *Improvements in bustles and crinolines, and in materials used in their construction.* Dated March 15, 1862.

This invention is not described apart from the drawings. *Patent completed.*

717. W. MCADAM. *Improvements in the manufacture of blocks, pulleys, and weights for window sashes and other purposes, and in the mode of applying the same.* Dated March 15, 1862.

This relates to the application of clay or other suitable mineral substance, either in the form of earthenware or glass, to the manufacture of blocks, pulleys, and weights, and which have hitherto been manufactured of metal. Under one modification of these improvements, as applied to the hanging of window sashes, the block or frame in which the pulley or pulleys run, is formed of clay, moulded to the required form, and afterwards glazed and fired in the usual way. The sheaves or pulleys are also formed of similar materials, and various kinds of clay, such as is used in the manufacture of porcelain and all kinds of earthenware. Instead of using iron or other metal for weights, it is preferred to make them of the heavier kinds of earthenware. These weights are either moulded solid, or with an internal cavity, to be filled with "mine dust," or other suitable mineral material, or which may be mixed with the clay for the purpose of increasing the specific gravity of the weights. *Patent completed.*

718. J. HUNTER. *Improvements in reaping machines.* Dated March 15, 1862.

This relates to reaping machines of the direct acting class. Under one modification the machine consists of an open rectangular frame, in the central part of which are fitted the bearings of the axle, carrying the main bearing wheel. The front part of the frame is prolonged outwards, and carries at its extremity an ordinary leading wheel, and extending laterally from the front of the main frame is the bar or frame carrying two knives or serrated cutters, the extremity of the cutter being supported on a wheel in the ordinary manner. On the axle of the bearing wheel, and outside the rectangular frame, is fitted a wheel or disc, the periphery of which is corrugated, or forms a series of undulations at right angles to the circumference of the wheel. This disc is keyed to the main axle, and it traverses within a longitudinal slot or opening formed in a movable bar, which slides to and fro in brackets projecting laterally from the main frame. At the extremities of the slotted opening in the sliding bar are two anti-friction rollers, and as the disc in the main axle rotates with the motion of the bearing wheel, the projections of the corrugated disc act alternately on the anti-friction rollers, and cause the sliding bar to traverse to and fro with a rapid reciprocatory movement. To the front end of the sliding bar is jointed a duplex link piece, the extremities of which are connected to two small shafts, arranged in a vertical position, and carrying at their lower ends bell crank levers. Each of these bell crank levers is connected to a serrated cutter of the ordinary kind; the cutters are arranged one above the other, and slide to and fro in the laterally projecting cutter bar before referred to. The rapid oscillatory motion of the sliding bar communicates a corresponding movement to the cutters, the duplex arrangement of the cutters admitting of a reduction in the extent of their lateral traverse, and a corresponding saving in the wear and tear of the moving parts. As the machine is moved forward, the crop is rapidly cut by the movement of the cutters at the parts where they cross each other, which, when arranged in this manner, operate with a scissor-like action. *Patent completed.*

719. J. GRANT. *Improvements in the construction of portable railways, and in the trucks or carriages to be used thereon.* Dated March 15, 1862.

The first part of this invention consists in securing plate rails upon longitudinal wooden sleepers, the ends of the sleepers having tongue and socket joints to fit into each other, to support the ends when a heavy weight is passing over them. The gauge of the sleepers is secured by means of transverse rods, with bent-up ends. The patentee proposes to fit the rods with pulleys for supporting a rope, if it be desired to work the carriages by means of a stationary engine. The patentee also proposes to fit the carriages with one pair of running wheels only, to enable them to pass round curves, which curves may be at right angles, the curved rails being used in combination with a movable or swivelling straight-piece. The second part consists in enabling one wheel to run loosely on its axle the other being made fast. The carriages are so made that they can be joined at their ends and form one long carriage; thus they are enabled to carry a bulky load. When necessary the carriages can be so formed as to be tipped up on end, or sideways, to deposit their load. *Patent completed.*

720. A. Y. D. SCOTT. *Improvements in the manufacture of cement.* Dated March 15, 1862.

Here the patentee claims subjecting lime in the pulverized state to the action of sulphurous acid gas, and an oxydizing agency, in the manner and for the purpose described. *Patent completed.*

721. S. N. DE LA H. DE BARBEZIERES. *An improved construction of horse shoe.* Dated March 15, 1862.

The object here is to provide for the feet of horses a roughened surface which, on the occurrence of a sudden frost, will admit of being readily attached to their hoofs and detached therefrom without the aid of a farrier, the ordinary shoes remaining undisturbed in their position, and ready for service on the breaking up of the frost. To this end the patentee has devised an expanding supplementary shoe, which has one of its quarters hinged at the side, to allow of its opening laterally, and then closing upon the ordinary shoe. *Patent completed.*

722. J. AVERY. *Improvements in purifying coal.* (A communication.) Dated March 15, 1862.

Here the coal is subjected to the action and heat of free steam, in a suitable enclosed chamber, and also to the chemical action of common salt, potash, quicklime, and sal ammoniac. *Patent completed.*

723. G. HAMILTON. *Improvements in tumbler locks.* Dated March 15, 1862.

This invention has for its object the so constructing tumbler locks that the proper positions of the tumblers, for allowing the bolt to be shot, may not be detected by applying pressure to the bolt in the well-known manner. For this purpose, the patentee mounts the tumblers on an eccentric, the pin of which is carried by the case of the lock. The tumblers are each capable of turning around the eccentric, and when the tumblers are correctly set by the key before the bolt is shut back, the eccentric will not be caused to turn on its pin, but when the bolt is pressed back, before the tumblers are correctly placed, the stump upon the bolt will press against the tumblers and cause them to recede, the eccentric, by turning on its pin, allowing them to do so. The turning of the eccentric on its pin he arranges to bring into action a catch or stop for the bolt to come against, and he also arranges the lock so that the bolt, when further pressed on, shall, by acting on the stop, cause the eccentric still further to turn on its pin, and so move back the tumblers away from the stump on the bolt, in order that the stump shall no longer press against them. *Patent completed.*

724. J. ROBEY. *Improvements in manufacturing and refining sugar, and in apparatus employed therein.* Dated March 15, 1862.

Here in place of using the ordinary vacuum or other pans now in use in the manufacturing and refining of sugar, a rotating vessel is employed of a suitable form, by preference of a cylindrical shape, with hemispherical or curved ends within which the saccharine fluid is placed and heated, the saccharine fluid only occupying a comparatively small portion of the cubic capacity of the vessel, by which means the saccharine fluid in the vessel will constantly gravitate to the lowest point, whilst the inner surface of the vessel above the body of the fluid therein will be covered with a film of the fluid, by which a very extensive and comparatively thin surface of the fluid will be presented for evaporation, and this effect of heating surface may be extended if desired, by making the rotating vessel of corrugated or other suitable metal. *Patent completed.*

725. W. PICKSTONE. *Improvements in the manufacture of piled fabrics.* Dated March 15, 1862.

Here a fabric is woven consisting of cotton warp wefted with cotton yarn, to form the ground or body of the fabric, and it is also wefted with a mixed weft consisting of cotton and woollen, or worsted yarn, such mixed wefting being suitably carried or floated on the face as to admit of the mixed weft being cut into a pile, as when weaving plush, velveteens, and such like fabrics as have their surface or floating wefts cut into a pile. By thus using combined weft for producing the pile of a fabric, a peculiar effect will be produced, when such fabric is dyed, by reason of the difference of tint, or character of colour imparted by the dye to the animal and to the vegetable fibre of the pile. *Patent completed.*

726. J. T. PENDLEBURY and T. PENDLEBURY. *An improved form of lubricator.* Dated March 15, 1862.

This consists in an improved form of grease cock for lubricating cylinders, pistons, pumps, and other mechanism,

which lubrication is effected by the action of the machine itself. The patentees construct the cock with a funnel at the top of the usual form for receiving the oil or other lubricating material: the cone or plug they make hollow, and fitted with a stuffing box and projecting spindle of any convenient form; the plug or cone has an aperture corresponding in size with the hole in the bottom of the funnel for allowing the oil to pass into it, and another hole is placed near this last-named one, coinciding with a tube passing up through the centre of the funnel holding the oil, having its mouth above the surface of the tallow or oil, for the purpose of allowing the escape of air. A third hole is formed in the opposite side of the plug from the two last-mentioned ones, which is turned off when the two others are in position, a pipe passing up through the funnel of the cock, connected with the inside of the cylinder, or with the boiler, so as to allow the passage of the steam up through it. This pipe is connected with this last hole. A passage is formed through the stem of the cock passing into the cylinder in the usual way. The operation is as follows:—the cock being turned so as to bring the aperture in it, so as to coincide with the hole in the funnel, the oil will run down and fill the hollow plug, the air going off by the pipe passing through the funnel; the plug is then removed by a lever, or other contrivance connected with the machinery, which brings it over the passage in the stem, and also the third hole in connection with the pipe from the cylinder or boiler, which by the pressure of the steam, forces down the stem and into the cylinder; the lever on the spindle then turns the plug, and the same action is repeated. *Patent completed.*

727. W. Clark. *Improvements in water meters.* (A communication.) Dated March 17, 1862.

This consists in the arrangement within a stationary cylinder or cylindrical pipe of two or more oblique-bladed wheels, secured at suitable distances apart on a central shaft, so applied as to rotate freely within the said cylinder or pipe, and two or more series of stationary spiral water passages surrounding the shafts in the spaces between the said wheels, such passages and the blades of the said wheels being set at angles of 45 degrees or thereabouts to the axis of the shaft and cylinder or pipe, but their obliquity being in opposite directions relatively to the said axis, so that water passing through the cylinder or pipe may be caused to strike the blades of the wheels perpendicularly, or nearly so, to the faces thereof; by this system of wheels and passages the water as it passes through the cylinder or pipe is made to act on the several wheels in succession, so that greater power is obtained to give motion to the shaft, and the indicating apparatus which is geared therewith than could be had with a single wheel, while at the same time there is no material increase of friction on the shaft. *Patent completed.*

728. A. S. Stocker and A. R. Stocker. *Improvements in the manufacture and construction of articles to be worn by bipeds and quadrupeds.* Dated March 17, 1862.

This invention consists in the manufacture of metal boot heels, and tips, by rolling or otherwise, forming the rods of iron out of which they are to be made so as to cause them to be indented or of an uneven surface, or surfaces, on those sides which have hitherto been rolled and used in a plain state, and in bending or countersinking such or other heels and tips. The invention also consists in the manufacture of horse shoes, by the use of certain dies, cast, sunk, or otherwise constructed in such manner, and of the desired configuration, into which iron or other metal having been before-hand properly prepared, is intended to be forced or pressed, which, by the aid of such dies, and the pressure applied thereto, and the article to be made will cause the crude metal to take the formation intended, any surplus web or waste attached to the shoe beyond its proper form being removed by the aid of clipping tools, as is well understood in the trade. *Patent completed.*

729. W. E. Gedge. *Improvements in the manufacture of crinolines.* (A communication.) Dated March 17, 1862.

Here it is proposed to accomplish the covering of crinoline steel by paper, in combination with net work or open tissue of very light fabric and inexpensive material. The paper of any colour is to be placed on each surface of the steel, and covered with the tissue, both being generally of the same colour, and the paper may be wound on the steel as a band, or plasted, or glued thereon. *Patent abandoned.*

730. W. B. Lord and F. H. Gilbart. *Improved means or apparatus for raising, lowering, and releasing ships' boats, or other heavy bodies.* Dated March 17, 1862.

In carrying out this invention the patentees pass through the kelson of a boat, amidships, or in the centre thereof, and under, or nearly under, athwart, a bolt or pin, securing the end thereof by a countersunk nut, a washer being placed between the nut and keel, or by other fastening. The bolt or pin aforesaid forms the shank of a metal block or head piece, and through this block is left a slot; a flat circular piece or disc, bearing a head and ring, is fitted into the block and works on a spindle within the slot; a portion of the disc is cut out to permit the introduction of two hooks into the slot, and each of these hooks is furnished with a notch and a hole through which to pass the light of the lowering ropes. The hooks are inserted side by side within the slot, but coming from the opposite direction, say right and left. When the hooks are in position within the slot, the head of the disc is (by means of a lanyard attached to a ring) pulled down, and it thus secures the hooks in position; and the greater the strain on the lowering ropes the firmer the connection between the disc and the notches of the hooks. From the eye and shank of each hook a rope (the lowering rope) passes to and through eye-bolts, secured in like manner as the centre pin, fore and aft in the kelson perpendicularly (or nearly so). Over these eye-bolts are lugged rings, or plates having lugs, and these rings or plates are held suspended over the eye-bolts by means of lashings passed through the before-mentioned lugs, and attached to the sides of the boat. The ropes which pass fore and aft from the shanks of the notched hooks serve to suspend the boat from the ship's davits, and by hauling on to or releasing these ropes from the belaying pins, the boat is raised or lowered. The apparatus may be cased in as far as the eye-bolts if desired. Either on the davits or on the side of the ship they fit a grooved catch or slide; at the end of the sennet or rope, which is passed over the boat to prevent its swaying with the motion of the vessel, they attach a slide pin, the head thereof fitting loosely into the grove formed in the catch or slide when the boat is secured, and sliding down and falling out of such groove when the boat is lowered. When it is desirable to lower the boat for service, the crew pass into her, she is then lowered from the davits at a signal from the officer in command, a lad pulls the lanyard, causing the head of the disc to assume a vertical position. This movement brings all the slots or openings in the block, disc, and hooks square with each other, the hooks are thus released, and the weight of boat and crew causes them to leave the block, pass through the eye-bolts and suspended rings, and the boat meets the water on an even keel. *Patent completed.*

731. L. P. Mongruel. *An improved cold vapour generator, which may also be used in the carburation of illuminating gas.* Dated March 17, 1862.

This invention is not described apart from the drawings. *Patent completed.*

732. W. Bowser. *Improvements in ships' fire-hearths or broiling and cooking apparatus.* Dated March 17, 1862.

This invention relates to a previous patent, dated March 8, 1845 (No. 10,576). The apparatus is of a rectangular form in plan, having ordinarily three boilers of different sizes at one side, heated by means of a fire-grate directly beneath them, whilst at the opposite side there is formed a cooking range with a separate fire grate and hot plate, and an oven or ovens occupy the middle portion, their doors being in the remaining sides. The flue from what may be termed the cooking or range grate is, according to one modification, made to immediately descend from the top of the grate down between the grate and the oven, and to pass thence under the oven, and finally to the uptake or chimney. By these means the oven is more satisfactorily heated than in the ordinary arrangements, in which the heat is applied in some cases to the top and sides only, and in others to the top and sides prior to being applied to the bottom. In another modification, whilst the flue is applied to the oven in the direct manner already described, there is introduced in addition a boiler to receive heat from the fire, such boiler having a part rising up a short distance between the grate and the first descending part of the flue, and passing under the horizontal part so as also to receive heat from that part of the flue. The steam generated in this boiler may be conducted by pipes to cooking utensils mounted on a light frame, at a sufficient height above the hot plate to leave the latter clear. The grate for heating the boilers is provided with an adjustable partition piece to permit of contracting the fire space when only one or two of the boilers are in use. The flue from the boiler grate passes inwards under the boilers, and a short distance up along their inner ends, whence it is continued downwards in a box or division at one side, and passing round and under the oven, finally unites with the flue from the cooking or range grate. The apparatus may be made with flues similar to those hitherto employed, and dampers or other contrivances may be used for diverting the fire gases from either grate into whichever series of flues may be described. *Patent completed.*

733. G. Davies. *Improved apparatus for drawing.* (A communication.) Dated March 17, 1862.

We cannot here give space to the details of this mention. *Patent abandoned.*

734. J. and W. Weems. *Improvements in apparatus for indicating the pressure or quantity, and in regulating the discharge of fluids.* Dated March 17, 1862.

One part of these improvements relates to the arrangement and construction of apparatus for indicating the pressure of fluids. One modification, as applied to a steam pressure gauge, consists of a diaphragm of india-rubber, metal, or other suitable material, fitted in a small steam chamber. To this diaphragm is attached a rod, the upper part of which forms a rack that gives motion to a wheel; depending from this wheel is a lever or rod with a ball or weight attached to its extremity. The spindle of the wheel projects through the dial or index face, which is graduated to show the pressure in lbs., and to this spindle the pointer or index is attached. When the pressure of the steam, air, gas, or other fluid acts upon the diaphragm, it raises the vertical rack, and moves round the wheel to which is attached the lever weight, and which serves to keep the index in a vertical position when not otherwise acted upon. The pressure on the diaphragm causes the lever weight to rise towards the centre, at the same time giving motion to the pointer, and thus indicates the pressure. *Patent completed.*

735. B. Todd. *Improvements in the manufacture of antimony and the oxide of antimony.* Dated March 17, 1862.

This invention consists in burning the sulphide of antimony, or the oxy-sulphide of antimony, by throwing it on a fire in a furnace, or by mixing it with a carbonaceous substance, and burning it in a crucible, retort, or furnace, and causing the ascending vapours to pass with a current of air through flues or condensers, by which process all the antimony contained in the ore will be deposited in the said condensers or flues in the state of oxide, and the sulphur volatilized in the state of sulphurous acid gas. To manufacture antimony the oxide of antimony obtained in the flues and condensers by the above process is to be mixed with a carbonaceous substance and alkali, and smelted in crucibles, or in a retort or furnace so arranged that any fumes arising from the process of reduction may pass into flues or condensers to be deposited. *Patent completed.*

736. W. Barford. *Improvements in rollers for rolling land.* Dated March 17, 1862.

For the purposes of this invention, in constructing a roller, whether consisting of one or more cylinders, in order that the same may be weighted with water more advantageously than heretofore, each roller or section of a roller is closed at its ends, the ends being connected by a suitable tube or hollow passage to allow of the axle passing through it. The ends of the tubular passage are strengthened or bushed where they receive and turn on the axle. The cylinder or cylinders used in constructing a roller may be of wrought or cast iron, and such is the case in respect to the ends or covers. These parts are put together water-tight, and such is the case in respect to the tubular or hollow passage which connects the two covers or ends of a roller or of a section of a roller. Each roller or section of a roller has an opening in it through which the supply of water is introduced, and such opening is closed by a screw plug, or by other convenient instrument. By these means each roller and section of a roller consists of a vessel closed at each end, with a hollow passage through the centre thereof, whereby the supply of water introduced for adding weight thereto may rise above the axle and even fill the roller or sections of which a roller is composed. *Patent completed.*

737. W. Barber. *Improvements in the manufacture of hats.* Dated March 17, 1862.

On the 2nd day of July, 1861, the present patentee obtained provisional protection (No. 1,675) for an invention consisting in curling, shaping, or tipping off the brims of hats by means of a mould of the form of the intended brim, with which the brim of the hat is forced in contact by means of an elastic bag, into which water, air, or other fluid is forced. He did not, however, proceed with his application for a patent for this invention, as he found practical difficulties in removing the hat from the mould after the brim was curled, which at that time he was unable to overcome. A part of this invention consists in a method of overcoming this difficulty, and this he does by employing, in combination with the bag and fluid pressure, as before explained, a mould made in sections or parts, so that the hat, when it is removed from the principal parts of the mould, takes with it some of the parts of the mould representing the brim, and which, were they not movable, would impede the withdrawal of the hat; these parts of the mould are afterwards readily removed from the hat. *Patent completed.*

738. G. T. Bousfield. *Improvements in cranks for driving sewing machines and other machinery.* (A communication). Dated March 17, 1862.

This invention consists in attaching the connecting rod of the treadle to two auxiliary pins, which are attached to and vibrate upon the crank pin, instead of attaching the connecting rod directly to the crank pin. And in connecting and disconnecting the said auxiliary pins alternately with and from the crank pin at the beginning of each stroke in such a manner that the advance auxiliary pin (considering the direction in which the crank is to turn) shall become temporarily fixed with respect to the crank pin, and perform the usual function of a crank pin, while, by the same movement, the rear auxiliary pin is loosened, and permitted to turn freely upon the crank pin. The said alternate connecting and disconnecting of the auxiliary pins with respect to the crank pin, operated by a treadle in the ordinary manner, produces a continuous revolution of the crank in one given direction, and avoiding all stoppage upon the dead centres. *Patent completed.*

739. J. M. Courtauld. *Improvements in power looms.* Dated March 17, 1862.

This invention consists in the introduction into the web or fabric in the course of manufacture of a slide, lever, or other mechanical agent connected with the gear, by which the loom is thrown in and out of work, and made to act when no shoot is laid in, in such manner as to throw the loom out of work. *Patent completed.*

740. J. Hicks. *Improvements in mercurial barometers.* Dated March 17, 1862.

This invention consists in terminating the barometer tube at top in a coil, instead of employing a straight tube as heretofore; and for some purposes in forming the tube throughout in the shape of a spiral coil. It is necessary that the length of straight tube, together with a straight line carried through the centre of the coil, should make up a length of from 31 to 34 inches; and when the tube is in the form of a helical coil from the bulb upwards, then a straight line from the bulb to the top of the coil must measure from 31 to 34 inches. The object of the invention is to obtain a more extended scale than is procurable with a straight tube. The inventor proposes that the scale shall be spiral, and that the coils or rings of the scale shall be placed between the coils of the barometer tube. *Patent abandoned.*

741. E. Smith. *An improvement in watch keys.* Dated March 17, 1862.

This invention consists in constructing watch keys which act in a similar manner to those known as "Brequets," but which are applicable to winding watches, whether the winding is effected by turning the key from right to left, or *vice versa*. In the brequet keys, a key winding by turning from right to left will not effect the winding of a watch where the key has to be turned from left to right. The improved key consists of a spindle united to a ball, or other piece free to be turned in a rotary direction, upon a pin carried at the upper part of a guard or cage, which cage is large enough to allow of the ball revolving within it, and which is connected at bottom to a collar within which the upper part of the spindle is freq to revolve. *Patent abandoned.*

742. W. Gossage. *Improvements in the manufacture of soda and potash.* Dated March 17, 1862.

The patentee claims the manufacture of soda and potash in a caustic state, by causing carbonate of soda, or carbonate of potash in a state of solution, to become filtered through slaked lime as described. *Patent completed.*

743. T. Waller. *Improvements in breech-loading fire-arms.* (A communication.) Dated March 17, 1862.

This invention cannot be described without reference to the drawings. *Patent completed.*

744. T. Myers. *Improvements in meters for measuring water, gas, or other fluids.* Dated March 17, 1862.

This invention consists, firstly, of a measuring cylinder furnished with valves, valve boxes, and ducts, so arranged as to act with the requisite sensitiveness, and that the action shall only be carried on during supply, and shut off immediately the supply ceases. The cylinder is fitted with a piston, having a piston rod protruding beyond the top of

the cylinder with collars thereon, between which works the end of a lever, supported by standards, with a roller at one end to prevent friction, the other end being forked to guide and work a slide valve, made of brass or other suitable material, or rollers which press upon a diaphragm-valve, made of india-rubber or other elastic or pliable material; such slide or diaphragm-valve covers several ducts (five for instance) but the patentee does not confine himself to any particular number of ducts, their shape, size, or position. The slide valve, or the rollers acting on the diaphragm, are so arranged as to press upon and close one or more of the said ducts at one time. Some of the ducts (two by preference) lead some (one by preference) to the upper and some (one by preference) to the lower part of the cylinder, and hence, upon water, gas, or other fluid being admitted by the supply pipe, it will, according to the position of the piston and the attached piston-rod, cause the opening of some of the ducts, and allow the water, gas, or other fluid, to enter either above or below the piston, and thus keep it in motion. *Patent completed.*

745. M. A. F. MENNONS. *Improved means of arresting headstrong or runaway horses.* (A communication.) Dated March 18, 1862.

This invention consists in the utilization of the shocks produced by certain descriptions of magneto electric, and electro magnetic, apparatus as a means of checking the course of headstrong or runaway horses. To this end a pair of flexible conductors, formed of single or tressed copper or silver wire, is inserted in the reins of the bridle, the forward extremities being each connected with a piece of moistened sponge, so attached to the muscol or cheek bands as to press, when in position, against each side of the horse's head at a short distance below the eye. The opposite extremities of these conductors, prolonged beyond the grasp of the reins, are fitted with rings or other suitable metallic attachment, so arranged as to be readily connected with the poles of an induction coil set within reach of the rider or driver as the case may be. *Patent completed.*

746. M. A. F. MENNONS. *An improved combination of cooling and filtering apparatus, forming a safe for the preservation of solid and liquid provisions.* (A communication.) Dated March 18, 1862.

This invention is not described apart from the drawings. *Patent completed.*

747. M. A. F. MENNONS. *The application to the manufacture of paper, pulps of a vegetable product not hitherto used for that purpose.* (A communication.) Dated March 18, 1862.

This invention consists in the application of the stalks or branches of the potato plant (solanum tuberosum) to the manufacture of paper pulps. The stalks or branches to be thus applied are cleansed, bleached, and reduced, by the processes adopted in the treatment of rags and other fibrous materials, and the resulting pulp is afterwards converted in the ordinary way into paper or cardboard of the different qualities required. *Patent abandoned.*

748. M. A. F. MENNONS. *An improved needle-threading apparatus.* (A communication.) Dated March 18, 1862.

This invention is not described apart from the drawings. *Patent abandoned.*

749. J. BANKS. *Improvements in electro-magnetic telegraph printing apparatus or marking instruments, or apparatus to be used in connection therewith.* Dated March 18, 1862.

These improvements in the arrangement of electro-magnetic telegraph printing apparatus and transmitters consist in employing two helical coils, which the patentee prefers to place vertically, and to use or employ projecting polar terminations, so that the armature may be attracted upward to the under side thereof, when the polar terminals are applied at the upper ends of the soft iron cores; and instead of employing a bar armature, one end of which is made to come in contact with each pole or polar terminal, he employs a circular armature, in the form of a disc or a wing, and mounts it upon a spindle or rod, held and guided parallel to the soft iron cores, with a means of adjustment applied at the step-bearing or pivot. This spindle or rod, with the circular armature is free to rotate, and so present a different part to each polar terminal from time to time. The spindle or rod is prolonged beyond the armature, and has on its extremity either a button-shaped striker, or a marker of any convenient shape. The marking part of the apparatus is carried by the same framing or mounting as the magnetic coils, and thus if the coils be placed vertically, and the marking or printing apparatus applied above them, the paper strip or ribbon may be indented from the under side, or inked, or otherwise marked on its upper face during its passage through the sheath or guide. Instead of employing a rotating disc mounted on a spindle, working in fixed bearings, such disc being free to revolve in the direction of the paper, or made to revolve in a contrary direction by means of clock-work, he either employs a roller similar to a printer's inking roller, mounted at a short distance above the paper, and capable of revolving freely, or he employs a thin cake, strip, or rod of solid ink, held or contained in a sheath, mounted in a carriage, or supported in any convenient manner above the paper, against the point of which solid ink-marker, or against the printer's ink-roller, the paper is pressed in contact during the transmission of the electric currents through the helices or coils; thus, on making and breaking contact, dots and spaces, or lines and spaces, are formed on the strip of paper. *Patent completed.*

750. H. BAILY. *Improvements in the manufacture of paper.* (A communication.) Dated March 18, 1862.

The machine employed to reduce the wood into pulp fit for paper is composed of a circular grater in tempered steel, presenting on its circumference a puncture or spiral cutting. This grater is mounted on a stand like that of a grindstone, and receives a movement of rotation from five to six hundred revolutions per minute. It is surrounded on all sides with a metallic envelope, of which the lower part is terminated by an orifice serving as a tunnel or feeder to the water and the pulp. In this envelope are bored in the upper part, and perpendicularly to the axle, one or several openings, serving as receptacles to the blocks of wood cut to their measure, which determined weights sliding on a vertical stem force against the asperitus that are presented by the points of the grater, so that, being in contact with the wood, this grater in its rotation bears on the ligneous fibres of the wood, and thus reduces them to filamentary pulp. On each side, and near the middle of the circumference of the grater, are two taps from which a jet of water flows, and detaches the pulp which might adhere to the points of the grater, and forces it towards the lower part of the envelope, so that it may flow into a frame or box lined with fine metal sheets, from which the water escaping leaves the pulp almost dry and easy to be transported to the cylinders to finish its entire preparation, to whiten and fix itself by the ordinary methods employed for pulp of rag. *Patent abandoned.*

751. T. DUNN. *Improvements in the construction of bridges, roofs, houses, and other structures.* Dated March 18, 1862.

This invention is not described apart from the drawings. *Patent completed.*

752. W. TONGUE. *Improvements in machinery and in processes for preparing, heckling, dressing, and combing flax, hemp, silk, and other fibrous materials.* Dated March 18, 1862.

Among the numerous features of this invention are the following:—According to one part of the invention the patentee first opens and straightens the fibres of silk, flax, hemp, China grass, rhea, or other fibrous materials of this character, by machinery similar to that described in the specification of a patent granted to Henry Rawson, dated January 27th, 1859 (No. 249), or by any of the improved arrangements of machinery for this purpose described in the specification of a patent granted to the present patentee, dated March 5th, 1862 (No. 596). Having thus previously prepared the fibrous material, he proceeds to form it into tufts in the ordinary manner, preparatory to subjecting the same to the process of heckling, according to another part of this invention. The arrangements of machinery and processes which are employed in carrying out this part of the invention consist in first opening and straightening the silk, flax, hemp, or other fibrous material, by the arrangements of machinery referred to for this purpose. He then conducts it, in the form of a sliver or otherwise, to a filling engine or other machinery for forming it into tufts, but he prefers for this purpose to conduct the fibrous material through a screw gill feeding apparatus, from which it is detached in the form of tufts by means of an ordinary nipper. The detached tufts are transferred to rotating combs, several of such detached tufts being accumulated upon each rotating comb, from which they are taken by hooks or holders preparatory to being placed in and operated upon by ordinary heckling machinery, or by that of the improved construction forming part of this invention. The hooks or holders of heckling machinery constructed according to this invention may be of the ordinary construction, but in place of moving them continuously through the machine, or bodily from opposite one set of heckles to another set, as heretofore practised, he causes them to travel through the machine by a step-by-step movement, the movement by preference taking place when the pins of the heckles are inserted amongst the fibres, and he causes the heckle plate or bar to partake of this forward movement, in order that the fibres may be maintained in a vertical position whilst being operated upon. Another part of the invention consists in the application of a reciprocating comb or combs to act as cleansing apparatus to the machinery for combing fibrous materials. *Patent completed.*

753. C. ILES. *Improvements in the manufacture of umbrellas and parasols.* Dated March 18, 1862.

This invention relates, first, to the construction of an improved top notch or runner notch for umbrellas and parasols. The second part of the invention consists in making middle bits for umbrellas and parasols in such manner that the parts which come into contact with the fork have a raised projection in order to strengthen and widen this part of the middle bit. The third part of the improvements consists in making the handles and tips of umbrellas and parasols of china, or other vitrified materials; also in the use of hard cement, such as Keene's, or any other similar hard cement capable of bearing a smooth and polished suface. Fourthly, the invention consists in making the heads of the rivets used for connecting the middle bits and stretchers of umbrellas and parasols of a rounded, dome, or scutching pin shape, and when the rivet is passed through the hole the inventor stamps in suitable dies a head of a similar form on the other end, or a washer may be placed on this end, which may be riveted or stamped, to connect the stretcher and middie bit firmly together, and by these means he makes a very strong and neat point. *Patent abandoned.*

754. A. A. BEAUMONT and J. A. ESCALIER. *A flying top.* Dated March 18, 1862.

This invention consists in the construction of a hollow top forming the centre of a helix, to which it is fixed; the lower part of the top is reduced in size to allow of its being adjusted to a handle made to receive it. The handle is hollowed out cylindrically at its upper part, in order to contain a bobbin, on which a small cord or a piece of string is wound for giving a to-and-fro motion to the bobbin, which is provided at its upper part with a cup of a concave form, to receive with facility the top. A hole is made in the handle for the passage of the cord or string. This toy is used by holding the handle in one hand, and imparting a rotary motion to the bobbin, to wind up the string; the top is then placed in the cup, and it is only necessary to pull the string to cause the top to fly off and turn in a vertical direction. *Patent abandoned.*

755. J. A. JAQUES, J. A. FANSHAWE, and F. JAQUES. *Improvements in the construction of elastic surface rollers.* Dated March 18, 1862.

The patentees claim the combination of the hard and soft compounds of india-rubber, known in this country as junction rubber, with any suitable core, for the purpose of producing elastic surface rollers, as described. *Patent completed.*

756. J. A. ROCKETTI. *Improvements in meteorological instruments and thermometers.* Dated March 18, 1862.

This invention consists in placing the engraved and graduated scales of thermometers, barometers, and other meteorological instruments, in either flat or round glass tubes, which may be sealed up at the ends, so that no water or air can get at them. The protected scales are adapted to the mercurial or capillary tubes by being secured along side of them on flat pieces of wood or metal in any convenient manner, and all the useful parts of the instrument being protected by a glass covering, it follows that little or no damage can result to the scale from atmospheric influences. *Patent abandoned.*

757. J. WRIGHT and H. WHEATCROFT. *Improvements in apparatus and machinery for lasting and making boots and shoes.* Dated March 18, 1862.

This invention consists of a machine for lasting boots and shoes when the uppers are secured and the inner sole is to be affixed. On a suitable stand or frame are mounted four sliding plates, two corresponding in outline to the sides of the boot or shoe, and the two others fitting the toe and heel. These plates are adjusted by screws to any size of boot, and slide in grooves, so as to open and shut by the action of two parallel shafts, on which are mounted cams, pressing against the two side plates; the ends of the two side plates are formed wedge-shaped, so as to embrace the two toe and heel pieces. By this means the inventors are enabled to contract the whole of the plates simultaneously when not acted on by the lever. The plates are kept open by a spring, and the last, with the upper leather and inner sole, is placed within these plates and supported from underneath at each end; the plates are then closed, which stretches the upper leather, and makes it to fit accurately the last. On the same spindle which actuates the slide are fixed pincers, which grasp the projecting edges of the leather, stretch it tight, and keep it so till the workman has pegged the upper to the inner sole, the tacks or pegs being put in through holes or slots in the edges of the sliding plates. *Patent abandoned.*

758. S. SLACK. *Improvements in the manufacture of stockings and other fabrics in circular knitting machines.* Dated March 18, 1862.

The object of the present invention is to introduce a seaming thread in that part of the work intended to form the back part of a stocking, corresponding in position with the seams in stockings, which are joined up the back, and this object is effected simultaneously with the working of the other parts of the machine. For this purpose a space is by preference left in the circular head by a needle being left out. In the space thus formed an extra thread is worked in, such extra thread by preference being a thicker thread. This extra thread is caused to loop alternately with the thread on the one side and on the other, changing from one to the other at every course. In order to effect this alternate working of the thick or extra thread with the thread on either side, the carrier of the thick or extra thread has imparted to it (by means of a cam or other suitable equivalent) an alternating motion. The mode of introducing the seaming thread at the back of a stocking made in a circular machine may, however, be varied. In like manner shirts and other like fabrics made in circular machines may be seamed at the sides or parts requiring such seams. *Patent completed.*

759. F. WARNER. *Improvements in cocks or taps.* Dated March 18, 1862.

For the purposes of this invention the valve spindle has formed on it a toothed rack, which is received into and works within the water or steam way of the tap or cock. The face of the valve is by preference circular, and is packed with a soft packing where it comes against its seat, which is preferred to consist of a projecting ring, with a thin edge, to enter the packing in the face of the valve. Or the seat may be packed or have a washer of soft material, and the projecting ring may be on the face of the valve. The toothed rack used is constructed as follows:—There is a slot formed through an extended portion of the spindle of the valve, on the inner surface of one side of which slot the teeth forming the toothed rack are formed in such manner that, when the pinion used with the rack is in its place, the diameter of the pinion nearly corresponds with the width of the slot. The axis of the pinion passes through a suitable stuffing-box into the interior of the body of the cock or tap. This stuffing-box is constructed in such manner that, by screwing down the packing which takes its bearing on the axis, the requisite friction is obtained to resist the tendency of the axis to turn with the force of the pressure of the fluid. It is preferred that the arrangement should be such that about a quarter turn of the axis of the pinion should be for opening and closing the valve. The lower end of the axis of the pinion is pointed, and has its bearing in a suitable cup. The guide spindle of the valve is made three-sided, the sides being hollow as heretofore, so that the water, or steam, or other fluid may pass freely on the three sides of the spindle, whilst the three angles of the spindle serve to keep the valve and spindle correctly in the water or steam way. *Patent completed.*

PROVISIONAL PROTECTIONS.

Dated May 22, 1862.

1548. P. R. Hodge, Tokenhouse-yard, London. Improved dinner, supper, breakfast, or dessert plate.

Dated May 31, 1862.

1648. T. T. Lawden, gun manufacturer, Birmingham. Improvements in certain descriptions of single and double-barrelled guns.

Dated June 19, 1862.

1806. H. Ruston, Northampton-road, Clerkenwell. Improvements in plaiting machines to plait cotton yarns, silk, or like fibrous materials.

Dated July 28, 1862.

2133. T. A. Favrichon, St. Symphorien de Lay, France, merchant, An apparatus for the speedy and economical heating of baking ovens, and also for using their excess of heat

Dated August 15, 1862.

2299. J. Barclay, Gravel-lane, Southwark, engineer. Improved machinery for the manufacture of nails.

Dated August 21, 1862.

2336. M. Wilkinson, Blackburn, Lancashire, carder. Improvements in carding engines, parts of which improvements are applicable to drawing and such like frames.

Dated August 26, 1862.

2365. G. Davies, Serle-street, Lincoln's-inn, civil engineer. Improved machines for washing skeins of cotton, linen, wool, or silk. (A communication.)

Dated September 1, 1862.

2420. W. Edge, Clerkenwell. Improvements in the manufacture of albert chains, and in the mode of securing the same to the vest of the wearer.

Dated September 4, 1862.

2446. W. Clark, Chancery-lane, London, engineer. Improvements in the manufacture of a blue colouring matter. (A communication.)

Dated September 11, 1862.

2495. W. A. Munn, Throwley House, Faversham, Kent, An improved apparatus for capping, loading, and closing cartridges for breech-loading fire-arms.

2497. G. Weeks, Bromley, Kent, ironmonger. Improvements in constructing frames, trays, pots, or holders for flowers, plants, or shrubs, growing or otherwise, with arrangements for their display, and also for drainage.

2499. F. Datichy, Mortimer-street, London, engineer. Improvements in steam engines.

2501. R. A. Brooman, 166, Fleet-street, London, patent agent. Improvements in implements for cultivating the soil. (A communication.)

2505. A. Barclay, Kilmarnock, North Britain, engineer. Improvements in locomotive boring and winding engines.

2597. J. and F. Walker, Leeds, flax spinners and copartners. Improvements in machinery for combing and carding or hackling flax, silk, wool, and other fibrous substances.

2509. T. Molineux, John Dalton-street, Manchester. Improvements in pianoforte actions.

Dated September 12, 1862.

2511. A. E. H. B. Butler, Kirkstall Forge Company, Leeds. Improvements in machinery for straightening and polishing cylindrical bars of iron and other metals.

2512. J. B. Smith, Bury, Lancaster, engineer. Certain improvements in washing and mangling machines applicable in part to steam dyeing and to bleaching.

2513. J. Thom, Canterbury-place, Lambeth, mechanical dentist. Improvements in mounting or fitting artifical teeth.

2514. J. R. Johnson, Stanbrook Cottage, Hammersmith, and J. S. Atkinson, Red Lion-square, Middlesex. Improvements in machinery for manufacturing printing types.

2515. J. Bower, Carlow, civil engineer. Improvements in railway sleepers.

2517. J. Howie, Hurlford, Ayr, North Britain, coal master. Improvements in the construction of the crossings and switches of railways.

2519. H. Higgins, Salford, Lancashire, machine maker. Improvements in machinery or apparatus for opening, cleansing, or carding cotton and other fibrous materials.

Dated September 13, 1862.

2521. W. Harkes, Lostock Gralam, Chester, agricultural implement maker. Improvements in machinery for mowing and reaping.

2523. M. Chadwick, Chapel-field, Manchester, machine maker. Improvements in machinery for doubling, folding, or plaiting cloth or other woven fabrics.

2525. T. W. Cowan, Kent Iron Works, Greenwich, engineer. Improvements in the construction of portable or fixed pumps.

2527. H. Bennett, Wombridge Iron Works, Salop, iron master. Improvements in machinery or apparatus for the rolling of wire rods.

Dated September 15, 1862.

2529. E. G. Chant, London, gentleman. Improvements in self-binding portfolios or holders for newspapers, music, documents, letters, and other papers, or for woven or other fabrics, which it may be desired to bind or hold together.

2533. W. L. Tizard, Mark-lane, London, engineer. Improvements in the construction of ships, vessels, cupolas, and forts, and in apparatus employed therein.

2535. J. Webster, Birmingham, Warwick, engineer. Improvements in the manufacture of nitric and nitrous acids, and other nitrogenous compounds.

Dated September 16, 1862.

2537. J. Whines, Pimlico, Middlesex, carpenter. Improved machinery for filling dipping clamps with tapers and match splints.

2539. J. G. Bunting, Trafalgar-square, Charing Cross, Middlesex. A mechanical horse break.

2541. S. Flexen, Braziers'-buildings, Farringdon-street, London. Improvements in apparatus for ventilating railway and other carriages.

2543. R. Moreland, jun., Old-street, St. Luke's, Middlesex. Improvements in machinery for preparing and cutting hops.

2545. H. Jordan, Southampton, engineer. Improvements in rotatory engines.

Dated September 17, 1862.

2547. L. Leigh, Seymour, Connecticut, United States. Improvements in certain machinery for stretching and glossing silk, wool, and other fibrous materials.

2549. R. Cranston, London, Edinburgh, and Glasgow, hotel proprietor. An improved washing machine.

2550. J. Simpson, Hulme, Lancaster, frame maker. An improved composition for coating or covering moulded or other surfaces, and in apparatus for applying the same thereto.

2551. W. E. Newton, Chancery-lane, Middlesex, civil engineer. Improvements in watches or time keepers. (A communication.

2553. J. Douglas, Blackfriars-road, Surrey, ironmonger and range manufacturer. Improvements in apparatus applicable to close fire ranges, usually termed kitcheners, for the purposes of ventilation.

2555. J. H. Johnson, Lincoln's-inn-fields, Middlesex. Improvements in gas burners. (A communication.)

Dated September 18, 1862.

2558. R. Kay, Castleton Print Works, Blue Pits, Lancaster, calico printer. Certain improvements in printing calico and other surfaces, and in apparatus connected therewith.

2560. W. H. Browne, Theobald's-road, and H. Armstrong, Manchester-street, gas engineers. Improvements in dry and wet gas meters.

2562. J. W. Woodford, Sutherland-street, Walworth, Surrey. Improvements in machinery and apparatus used for driving and drawing piles, also for raising soil, and also in shoes and hoops for piles.

Dated September 19, 1862.

2568. J. Smith and W. Smith, Collyhurst, Manchester, dyers and finishers. An improved combination of machinery or apparatus for doubling, measuring, and plaiting woven fabrics.

2570. D. C. Bridge and J. Dyson, Halifax, York, boiler and hot water apparatus manufacturers. Improvements in the formation of boilers to be employed for warming buildings and similar puposes.

2572. F. Savage, St. Nicholas Iron Works, Lynn, Norfolk. Improvements in traction engines.

2576. C. Chinnock, Brooklyn, New York, merchant. Improvements in the construction of corkscrews.

2578. E. Feis, Sise-lane, London, merchant. Improvements in the construction of locks, catches, or fastenings for purses, bags, or other receptacles. (A communication.)

Dated September 20, 1862.

2580. H. R. Fanshawe, Leadenhall-street, London. Improvements in the mode and means used in fishing in seas, rivers, and other waters.

2584. A. Prince, Trafalgar-square, Charing Cross, Middlesex. Improvements in steam, boiler, and other furnaces and in apparatus for feeding the same. (A communication.)

Dated September 22, 1862.

2586. J. Sanderson, Clerkenwell, Middlesex, dressing-case and desk maker. Improvements in writing desks and cases.

2590. M. Vogl, Sambrook-court, Basinghall-street, London, merchant. Improvements in fastenings for leggings and other articles of wearing apparel.

1670. G. Gurney. Production and application of artificial light.

1673. J. Biers. Shoes for horses and other animals.

1675. J. L. Norton. Raising and forcing water.

1678. G. Peel, and J. Simpson. Working hydraulic presses.

1691. E. Conroy. Machinery for cutting corks and bungs.

1694. J. Bell. Fastenings for railway chairs.

1701. E. Conroy. Cutting corks and bungs.

1702. G. Hadfield. Manufacture of casks or barrels.

1708. A. V. Newton. Knitting machinery. A communication.

1748. F. Tolhausen. Surgical injecting apparatus. A communication.

1763. W. E. Newton. Improvements in fire-arms. A communication.

1764. W. E. Newton. Elongated bullets. A communication.

1782. W. J. Curtis. Screw Propellers.

1864. F. Tolhausen. Lock or locking apparatus. A communication.

1911. W. E. Newton. Picking or gathering cotton. A communication.

1954. P. B. O'Neill. Screw wrenches or spanners.

2013. H. Barber, and H. De Garrs. Rolling metals.

2042. R. Dunn. Furnaces.

2044. J. Dickson. Manufacture of caustic soda and carbonate of soda.

2083. R. Grogan. Screw propellers.

2101. J. Dickson. Treating copper ores.

2147. A. Boyle, and T. Warwick. Manufacture of ribs and stretchers of umbrellas.

2228. J. Macintosh. Obtaining and applying motive power.

2253. J. Dickson. Treating zinc ores.

2254. J. Dickson. Treating ores.

2265. J. Dickson. Manufacture of chlorine for commercial purposes.

2395. H. Jones. Breech-loading fire-arms.

2488. F. Hands, and H. Holland. Manufacture of black ornaments.

2537. J. Whines. Machinery for filling dipping clamps with tapers.

2602. W. Clark. Signalling. A communication.

The full titles of the patents in the above list can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list who have given notice of their intention to proceed, within twenty-one days from the date of the *Gazette* in which the notice appears, by leaving at the Commissioners' office particulars in writing of the objection to the application.

PATENTS ON WHICH THE STAMP DUTY OF £50 HAS BEEN PAID.

2218. W. H. Buckland.
2228. A. S. Stocker.
2286. W. Brookes.
2262. W. E. Newton.
2263. W. E. Newton.
2267. J. Macintosh.
2269. J. Macintosh.
2274. E. O'Connell.
2312. A. Whitock.
2277. W. Macfarlane.
2283. W. E. Newton.
2306. C. F. Beyer.

PATENTS ON WHICH THE STAMP DUTY OF £100 HAS BEEN PAID.

2191. J. R. Musgrave, R. Musgrave, and J. Musgrave.
2184. W. Kempe.
2267. J. Thornton, A. Thornton, W. Thornton, and H. Thornton.
2230. T. Dickens.
2232. F. C. Lepage.

PATENTS APPLIED FOR WITH COMPLETE SPECIFICATIONS.

2602. W. Clark, 53, Chancery-lane, engineer. Improvements in signalling. (A communication.) Dated September 24, 1862.

2612. M. A. F. Mennons, 24, Rue du Mont Thabor, Paris. Improvements in the construction of chair settees. (A communication.) Dated September 25, 1862.

LIST OF SEALED PATENTS.

Sealed October 3, 1862.

956. T. Silver.
959. G. Moulton.

Note.—Specifications will be forwarded by post from the Great Seal Patent Office (publishing department) on receipt of the amount of price and postage. Sums exceeding 5s. must be remitted by Post Office Order, made payable at the Post Office, High Holborn, to Mr. Bennet Woodcroft, Great Seal Patent Office.

THE
MECHANICS' MAGAZINE.

LONDON, FRIDAY, OCTOBER 17, 1862.

ENGINEERS AFLOAT.

It is a fact which is discreditable in the highest degree to the Board of Admiralty, that the steam officers of the British Navy continue to labour under disabilities and annoyances of the most irksome and humiliating character. We make this assertion deliberately and advisedly, and we have the fullest evidence of its truth. From all quarters the same information comes to us, and it is time, therefore, that an alteration, sweeping and effectual, should be made. It is not to be borne that a body of men, whose ability and intelligence are at least on a par with those of any other class of the community, whether ashore or afloat, should be treated in the scurvy way in which Naval Engineers have been and are being treated by those whose duty it is rather to honour and respect them. It it a truism which none can gainsay that the safety of this nation and certainly its maritime supremacy, are dependent at this moment upon the efficiency of engineers. Upon them do we rely for those scientific improvements and modifications in the arts of war which are the characteristics of the age in which we live, and which must determine the question of our national independence. Ashore, this truth is recognized to the full, both by those in authority and the public at large. Afloat, if we may judge by the conduct and language of those who may be termed, for convenience sake, the sailing officers of the Navy, it appears neither to be understood nor recognized. These latter, "dressed in a little brief authority," take every opportunity of exerting their power and influence to the disadvantage of their brother officers of the steam department. The natural consequence is, that there is scarcely a ship belonging to the British Navy wherein discontent and dissatisfaction do not prevail among the Engineer officers. The root of this fearful evil—an evil which might, in case of war, be fraught with the most fatal consequences—lies undoubtedly in the system adopted by the Admiralty for supplying the navy with Engineers. That system, therefore, must be remodelled before a radical and salutary change can be made in the position of the class of officers of whom we speak.

The whole of the existing arrangements for the enlistment of young Engineers into the Navy are of a one-sided, and "one-eyed," character. The advantages are all with the employers, and the disadvantages with the employed. What can be more unjust, for example, than the bargain by which a young man is entered on the Government books as a Probationary Engineer for one year, at the expiration of which he may be dismissed at a moment's notice, but cannot dismiss himself? If at the end of that period his imperious masters at Whitehall think proper, they may cancel his appointment as Acting Second Class Assistant, but they do not leave him the same option. He becomes, indeed, to a certain extent their slave, and cannot claim his discharge however he may desire to quit a service in which he finds contumely and social degradation, instead of honour and moral dignity. If he happened to be on a foreign station, forcible detention would prevent his leaving the ship, and should he escape from durance vile he is a deserter! Is not this a state of affairs which should cease? Is it compatible with those notions of justice and fair dealing which happily distinguish the Anglo-Saxon race? Would it be tolerated in engagements with individuals instead of the Board of Admiralty? Is it extraordinary that the desertion of Engineer officers from the Navy should be of constant recurrence? Is not the system, as we have said, "one-sided and one-eyed"—one-sided in giving a supposed advantage to the Government—and one-eyed in looking only at the convenience of the employer, and not regarding that of the employed? We put these questions to the Admiralty and to the public, and we have no doubt at all as to the answer of the last-named referees, however obliquity of vision may influence the replies of the former.

Again, we ask why a Second Class Assistant who has passed for a first class should be kept out of his promotion, as he almost invariably is, for nine or twelve months? Or why is a First Class Assistant under similar circumstances made to wait for *his* promotion to the rank of Engineer for a like period, or perhaps even longer? Assuredly these are grounds for dissatisfaction—legitimate dissatisfaction—and they have to be encountered on the very threshold of the service. The pernicious system applies to no other class of officers in Her Majesty's service, and it is therefore a badge of inferiority, and one which is too often made use of to the disparagement of the unfortunate Engineer. This is another disability which the Admiralty have the power to remove, although it appears they have not the inclination. Many of the remarks we have thought it fit to make respecting Engineers afloat, have taken the form of queries, but we have by no means exhausted the list. We should be glad to learn, for instance, the "reason why" no promotions at all take place among Naval Engineers on foreign stations, when death, invaliding, or other causes create vacancies on board Her Majesty's ships on those stations. It may be fairly assumed that there are present First and Second Class Assistants who are in all respects qualified and eligible for filling the vacant posts of Chief Engineer, Engineers, and First Assistant Engineers, and, except for the purpose of keeping alive disaffection, there seems no reason at all for shutting the door of promotion in their faces. It is a fact, nevertheless, that in August last no less than nine such vacancies remained unfilled on the Pacific station—the consequences being anything but pacific to those who were baulked of their fair expectations.

These grievances are a sample of many of which Naval Engineers have to complain, and of which it shall be ours to attempt zealously to free them. They are all remediable, and the first step towards effecting a cure is to discover and make known the seat and nature of the disease. As to the second series of evils to which reference has been made, they are of a more practical nature, and involve the social status of the Engineer afloat, his position in relation to his brother officers, the ship's company, and the accommodation provided for him in his floating home. These are all questions which are worthy of ventilation and which *must* eventually be solved satisfactorily to the persons most interested in them. The time is approaching when the importance of Naval Engineers, their talent and their usefulness, *must* be acknowledged, even by those who now seek to debase them, and who in many instances are intellectually and morally the inferiors of the men they spurn. The days of "class feeling"—a spurious bantling begotten of Ignorance and Pride, and without a trace of real "gentle blood" in its veins—are numbered, and the sailing officers of the British Navy had better prepare for burying it "deep in the ocean's bosom." It is *real worth* which is now regarded with favour by Englishmen generally, and not that adventitious and emasculate thing *empty rank*, which has too often elbowed its neighbour out of doors, or off the quarterdeck. So is there hope for Engineers afloat.

IRON WALLS AND NAVAL GUNS.

TO THE EDITOR OF THE "MECHANIC'S MAGAZINE."

Sir,—A few months ago you liberally allowed me space in your columns to lay before the public my views on the absorbing question of the "Iron-Walls of Old England." I availed myself of the valuable privilege to some extent, and I had the satisfaction of contributing to rouse public attention to the subject. The constant agitation of the leading point, relating to the construction of iron armour and naval guns, in which the Mechanic's Magazine took the lead, resulted, whilst Parliament was sitting, in the abandonment of the Spithead forts, and the *amende honorable* by the Admiralty to the Iron Plate Committee, in a public acknowledgement of its public services. The handsome terms in which the chairman, Sir John Hay, and his colleagues, were mentioned by ministers in the House of Commons, lest the impression that the baleful influence of the controller's department would be overruled with reference to iron-clad ships, and the board be guided by better counsels.

A short time has sufficed to dissipate those favourable impressions. In the construction of ships' armour the recommendations of the committee are disregarded; the men of wood are again rampant; and if Parliament do not interfere we shall have millions again wasted in armour plating of the Warrior type, or on wooden ships partially protected on the "Reed" principle.

When, in accordance with the public professions of the Admiralty, it was rational to conclude that the cause of truth and justice prevailed, I closed my correspondence; but, under existing circumstances, I ask your permission to resume it. I have no pretention to lead the public, but the opinions I may offer, founded on experience and observation, may encourage and give activity to discussions which, affecting as they do the maritime supremacy of England, are of momentous character.

In my former letters I endeavoured to develop the rudiments of the art of armour-plating ships and batteries. These are now understood and canvassed by a great number of engineers, mechanicians, and ingenious inventors, and may be left to work their way.

The question has assumed large proportions. Principles are applied on a vast scale. Nations are constructing iron-cased ships and naval guns, whose efficiency is tested in real or mimic warfare. Plans are propounded of invulnerable armour, and of guns and projectiles which will penetrate plates of any thickness. It is no longer possible to separate the attack from the defence. Gunnery and fortification applied to ships have no scientific or practical value apart from each other. The power of the gun has to be measured as much by the armour it has to penetrate and destroy as by its own intrinsic force. This is the view to which public attention must be directed. It is that entertained by foreign governments and sedulously prosecuted by experiments in several States. As a case in point, we have an apt illustration at home, of which the features are sufficiently singular and instructive to deserve notice.

The Admiralty had two pets—the Armstrong gun and the "Warrior" frigate. Both were ushered into the world by Tory and nurtured by Whig Lords. They were equally defects of solicitude to the Administration and the Opposition; neither could see the defects of their favourites, however evident to other persons. One of these pets has fallen into disgrace and is abandoned. The Armstrong gun has absolutely failed to fulfil its promise. All the favour lavished upon it has been in vain. All the boastings, exaggerations, and concealments practised for more than two years have failed to hide or palliate its deficiencies; and its complete failure is acknowledged by its best friends. Sir William Armstrong, it is determined, will be superseded. Our readers may rely upon that fact.

The "Warrior" is the remaining child of misfortune. It has its defects, and is a cruel disappointment to its patrons, but it is the surviving hope, and must not be abandoned. The strongest efforts are made to conceal its shortcomings and prolong the spurious popularity into which it has been forced by never-ceasing panegyrics.

Let us examine the "Warrior's" claims to public indulgence. Her advocates assert that, "to the credit of her architects (meaning the "Admiralty constructors), she creditably holds "the field against her assailants," and in evidence of that assertion it is assumed that the result of the last experiments at Shoeburyness has proved that, "taking a ship's battery "against a ship's armour, the superiority is on "the side of the latter." We demur to that assumption, and will proceed to show that the arguments on which it is founded are a series of fallacies and misrepresentations, similar to those which so long denied the defects and concealed the failure of the Armstrong gun.

It is said, first, "That a gun of 95 cwt., or "less than 5 tons, is the *heaviest* that can be "worked with success, or even safety, on "board a floating vessel." Second, "That "not one of the guns which pierced the 'War-"'rior' target can be considered as a ship "gun." Third, "That so long as she keeps "at sea she cannot be touched at all." Fourth, "That no *ship's gun* yet produced would be "effective against a first-rate iron-cased ship "(meaning the 'Warrior.')" Fifth, "That a "gun meant to pierce the 'Warrior's' sides "is either too light for its purpose or too heavy "to be carried at all." Sixth, "That it is pos-"sible we may have a vessel produced which "will carry a seven-ton gun," but that is not "the case at present. Seventh, "That it is "only a shore-gun that can pierce the 'War-"rior's' sides, and that only within a very "short range." Eighth, "That we have "frigates actually afloat which can resist any "gun yet tried of proportions available for "naval service."

This is the case of the Admiralty to uphold the falling reputation of the "Warrior." We cannot but declare our unqualified amazement at the boldness which gives utterance to such a tissue of unfounded assertions. They are all based on one eggregious error or voluntary mis-statement, with which we must deal in plain terms, to open the eyes of the untechnical public to the scandalous manner in which they are imposed upon.

It is not true that first-class iron-cased ships, such as the "Warrior" or the "La Gloire," cannot carry or work a gun heavier than 5 tons. Either of those frigates can and will carry guns of 7, 10, or 12 tons weight; that is to say, 90-pounders, 120-pounders, or 150-pounders, throwing solid and explosive projectiles which will penetrate the armour of the "Warrior." This at the Admiralty is a fact so well known that, if the 150-pounder Armstrong, which burst under trial, had been a success, the gratifying announcement would have been made to the country, that this tremendous weapon, whose destructive powers surpassed those of every other gun—because it was an Armstrong—would be adopted as part of the armament of the "Warriors" and "Northumberlands."

In fact, there is no reason why guns of that weight and calibre should not be carried and worked on board war ships of 5,000 or 6,000 tons burden. Any one who has paced the gun deck of the "Warrior" and inspected its structure—the massive iron girders, the strong planks and iron plate of which it is constructed, and the iron columns which support it—must be convinced that even a 24-ton gun could be trained and worked on that deck with the same ease as on *terra firma*. The number of guns, of course, would have to be diminished, to keep down the aggregate weight of metal to that of the complement of the guns originally designed as her armament. Thus, a frigate pierced for 50 five-ton guns would carry 36 of seven tons, 25 of ten tons, or 22 of twelve tons, without in the least affecting her displacement. The number of gunners would not be increased, and the probability is, that with the greatly increased space on the gun deck between the posts obtained by reducing the number, those heavy guns would be served and worked with greater facility than the larger number of lighter guns. It needs no argument to explode the specious assumptions put forth on behalf of the Admiralty to prove the invulnerability of the "Warrior" system of armour plating.

If, as we pointed out in a former article, a "La Gloire" be mounted with 120 to 150-pounders, her guns will, in a contest at short or long range, penetrate the "Warrior" plates, and speedily place her *hors de combat*. It is idle to keep up any delusion on that point. The recent experiments have proved conclusively that 4½-in. and even 5½-in. plates on wood backing, can be pierced through and through by 120 and 150-pounders; and also that even 68-pounders, at 200 yards, will destroy through-bolt fastenings, so that large plates will fall bodily off into the sea. The magnificent qualities of the "Warrior," as a sea-going ship, are constantly lauded, and, we admit, with much truth. Albeit, she "rolls awfully" in a rough sea-way. But these laudations are dust thrown in the eyes to conceal the real defect. The only question in this controversy is the *system of armour plating*. That system for the "Warrior" is 4½ in. of iron on a backing of 18 in. of teak, each plate weighing 4 to 5 tons, and fastened to a half-inch iron skin, with 1¼-in. through-bolts, and corresponding holes drilled through the plates. These are all sources of weakness. The system is defective. The wood backing offers no resistance, and is crushed into shreds by shot or shell.

You some time ago, in discussing the Spithead forts, refuted the arguments of a great daily authority by reminding him that ships would not come within the range of forts to be shot at, and therefore floating defences, which could move to the attack of invading ships, would be the most effective harbour defences. He now informs us, in your own words, that "*Ships will have to fight ships,*" to which I will add, what he seems to forget, that in the future, as in all past naval battles, the main and decisive conflict will not be at ranges of 1,000 or 600 yards, or even at 200 yards, but muzzle to muzzle, and I know I shall not be a false prophet in predicting that under such conditions a few broadsides of 68-pounders will smash the iron mail and destroy the fastenings of 4½-inch plates fitted with through-bolts to a wood backing.

The main question now is the improvement of naval armour. The construction of the iron cuirass of ships is a new science, which is yet in its infancy. It must not be supposed that the Lords of the Admiralty have, per saltum, attained perfection in the "Warrior" system. They may be too proud to listen to advice out of the circle of their own department, but misadventures, as in the case of the Armstrong pet, will, in spite of official resistance, force upon them the conviction that the chief cause of the "Warrior" target failures is the radical weakness of the system.

Mr. Whitworth, in his letter to the *Times*, has fully corroborated your exposure of the unfair report in the *Times* of the last experiments at Shoeburyness. With proper independence he refuses to allow one iota of the credit due to him alone for the success of his gun to be artfully claimed for Sir William, who, by the ill-advised advocacy of the *Times*, may truly be said to be in the mortifying predicament of the jackdaw stripped of the peacock's feathers.

CIVILIAN.

INTERNATIONAL EXHIBITION. JURY REPORTS.

CLASS VIII.—MACHINERY IN GENERAL.

JURY.

L. R. Bodmer, Switzerland; Consulting Engineer.
Chevalier de Burg, Deputy Chairman, Austria; Imperial Councillor; President of the Society of Arts and Manufactures at Vienna.
Earl of Caithness, London.
M. Chevalier, Chairman, France; Senator; Member of the Institute.
J. Hawkshaw, F.R.S., F.G.S., London; President of the Institution of Civil Engineers.
J. Hick, C.E., Deputy Chairman, Bolton; Civil Engineer.
J. M. da Ponte Horta, Portugal; Professor of Mathematics at the Polytechnic of Lisbon.
W. M. Neilson, C. E., Glasgow; Civil Engineer.
John Penn, C.E., London; Mechanical Engineer.
O. Pihl, Norway; Civil Engineer.
Du Pre, Belgium; Honorary Chief Engineer of Bridges and Roads.
W. J. Macquorn Rankine, Secretary, Glasgow; Professor of Mechanics in the University of Glasgow.
F. B. Taylor, United States; Mechanical Engineer and Designer.
H. Thomas, Zollverein, Berlin; Manufacturer.

ASSOCIATES.

Carl Jenny, Austria; Councillor and Professor in the Imperial Royal School of Mines at Chemnitz.
Paul Luuyt, France; Engineer to the Imperial Corps of Mines.

GENERAL EXPLANATIONS AND REMARKS.

1. This jury held in all, thirty-three meetings, commencing on the 7th of May, and terminating on the 20th of June, 1862.

2. In the course of those meetings they examined, considered, and adjudicated upon all the articles properly included in or transferred to Class VIII. which were mentioned in the Official Catalogue and ready for inspection, up to the date of their last meeting, with the exception of a few articles which, after careful search, they could not find, and of the fire-engines, which were submitted to a special Jury, for reasons which will be explained further on.

3. The Jury would have awarded medals to the following two articles, had they not been prevented from so doing, by Clause 5 of the Decisions of Her Majesty's Commissioners regarding Juries, because of the articles in question being exhibited by members of this Jury:—

United Kingdom:—

1801. Bodmer, R., and L. R.: Safety-valves for steam-boilers.

1955. Penn, J., and Son's: Marine engines, and parts of marine engines.

4. In considering the practical operation of the articles submitted to them, the Jury were careful

to come to no conclusion except such as was founded either on their own experience and observation, or on the authentic records of the experience and observation of competent persons not specially interested in the articles. Consequently, in the event of an article not having honours awarded to it by the Jury, it does not in every case follow that the Jury considered that article as having been proved to be faulty; but only that they were not able to obtain, during the time of their proceedings, evidence of its practical efficiency of that kind which they considered as alone sufficient to justify the awarding of honours.

5. Considering the shortness of the time allotted to them for completing their awards (viz., from the 7th of May to the 14th of June inclusive, afterwards extended to a few days longer), the Jury came to the conclusion that it was impracticable for them to institute exact experimental investigations, under their own superintendence, upon the mechanical efficiency of the various kinds of machines submitted to them.

6. Her Majesty's Commissioners, however, considered it desirable that such experiments should be made in the particular case of fire-engines; and inasmuch as the Jury could not undertake the superintendence of such experiments, that duty was intrusted to a special committee or Jury on fire-engines, to whom, also, the duty of making awards upon the fire-engines exhibited was transferred by Her Majesty's Commissioners. The awards of honours to fire-engines are nevertheless included in the general list of awards in Class VIII.

7. In adjudicating upon the articles contained in this class, it was necessary, for the sake of order and clearness, to divide them into subdivisions and sections; and in so doing the Jury were guided by the scheme of classification published in the Jury Directory.

8. It has been found impossible to avoid a few anomalies in classification, arising chiefly from the following cause:—The division of articles in the first edition of the Official Catalogue was unavoidably to a certain extent imperfect; and, in fact, the inspection of the Jury was in many cases necessary in order to determine to which class an object properly belonged. This Jury, during the earlier part of their proceedings, endeavoured as far as possible to correct those imperfections in classification, by causing some articles to be transferred from other classes to Class VIII., and some articles to be transferred from Class VIII. to other classes. When the time for the completion of the awards, however, came to be near at hand, this Jury considered that to persist in proposing such transfers would be to incur the risk of causing articles to be overlooked altogether while being passed from class to class; and, therefore, during the latter part of their proceedings, they adjudicated upon all articles that came before them, without considering strictly whether such articles properly belonged to Class VIII. or not; and hence a few articles are to be found in their list of awards which might with greater propriety have been classed elsewhere; for example, as "manufacturing machinery" (Class VII.).

9. Before commencing any remarks on special articles or kinds of articles in this subdivision, it may be stated that a large proportion of the honours awarded are granted for such reasons as "good workmanship," "good arrangement," "practical utility," "practical success," &c., and that in such cases, for the most part, it is unnecessary to give any special explanation in addition to the simple statement of the reason in the list of awards. Special explanation is chiefly required in cases where the article contains something new or unusual. Hence it is obvious that the space occupied by special explanations of articles in the sequel of this report is not to be taken as an index of their comparative merit or importance in the opinion of the Jury.

10. Agreeably to the recommendation contained in the first paragraph of page 12 of the Jury Directory, the Jury were most careful in admitting claims of novelty of invention; and in particular they sedulously endeavoured to avoid making any statement or remark which might be construed into an attempt to decide a question of patent right; for they considered that the decision of such questions was foreign to their duties.

11. In conclusion of these general explanations and remarks, it may be stated, that when the machinery of the present Exhibition is compared with that of 1851, it is found to be marked less by originality of invention, or the introduction of new principles, than by improvement in details, workmanship, and material; and that with respect to material in particular, the most striking improvements are those which consist in the greatly extended use of steel, and of iron approaching to steel in its properties.

Special Explanations and Remarks.

Subdivision I.—Prime Movers.

Section I.—Boilers, Furnaces, &c.

With a few exceptions, the actual boilers exhibited (as distinguished from drawings and models) belong to traction-engines, or to portable or semi-portable steam-engines; and those boilers are marked on the whole by efforts made with greater or less success to economize space, and to facilitate cleansing and repairs by means of improved arrangements of the heating surface, or otherwise. The following examples may be cited:—Bray's traction-engine (United Kingdom—1,805), Ransomes and Sims' portable steam-engine (United Kingdom—1,961), J. Taylor and Co.'s traction-engine (United Kingdom—2,004), Tuxford and Son's engines (United Kingdom—2,195), J. F. Cail and Co.'s engine (France—1,144), Farcot and Son's condensing steam-engine (France — 1,152), Hediard's boiler (France — 1,131), Laurens and Thomas' boiler (France—1,151), Zambeaux's portable boiler (France—1,137), Albaret and Co.'s portable steam-engine (France—1,207), Henschel and Son's boiler-tubes (Hesse-Cassel—434).

Many of the boilers are provided with the means of super heating steam, either by passing it through tubes in the smoke-box, or by enclosing the steam-chest in a smoke-box or flue.

In the engine exhibited by Mr. Wenham (United Kingdom—2,019), the steam, after having performed part of its work in a smaller or high-pressure cylinder, is supplied with heat while in the act of expanding during its passage from that cylinder to the larger or low-pressure cylinder. This application of heat to steam is at once sound in principle and successful in practice.

The most new and unusual in form of the boilers exhibited is that by Mr. Harrison (United Kingdom—1,877), which is an American invention. It consists of a number of hollow cast-iron globes, all equal and similar, connected with each other through cylindrical necks or short tubes, the whole being bound together, in a rectangular arrangement, with wrought-iron bolts. A boiler of any required size can at once be made by building and bolting together the proper number of globes and necks. The water and steam are inside, the fire outside.

M. Grimaldi (Italy—1,001) exhibits a cylindrical boiler, containing either flues or tubes for the flame, and turning slowly about a horizontal axis, so as to bring every part of the surface in contact with the liquid water and with the steam alternately, in order to increase the efficiency of the surface in raising steam, and prevent over-heating and corrosion.

The boilers shown by Mr. H. Cater (United Kingdom — 1,814), (presenting a peculiar arrangement of tubes), although they were set up too late to be the subject of an award, may here be mentioned as being at work in the boiler-yard of the western annexe, with satisfactory results.

The following articles fall especially under the head of furnaces and their appendages:—

An apparatus for promoting perfect combustion and preventing smoke, by u ing very small jets of steam to blow streams of air into the furnace, is exhibited by Mr. D. K. Clark (United Kingdom—1,822). Its practical success has been well established. It is at work in the boiler-yard.

Sieburg's improved grate (Prussia — 1,320), and Schulz, Knaudt, and Co.'s fire-box (Prussia —1,318).

In M. Hubazy's portable engine (Austria — 569) the furnace is adapted for the burning of straw—a most useful contrivance where other fuel is scarce.

The apparatus of M. Steenstrup (Norway—213) is intended for the prevention of rust in boilers. The exhibitor takes advantage of the chemical affinity of chloride of calcium for water, so as to dry completely the rust already formed, which consequently falls to powder and detaches itself from the boiler.

The "Hydratmo-Purificateur," or water-softening apparatus, exhibited by M. Durenne (France —1,163), purifies water from salts of lime by the aid of its property of depositing such salts when raised to a high temperature. A rectangular case contains, one above another, a series of horizontal trays or platforms, heated by means of the waste steam of the engine, which enters at the bottom of the case, and slowly ascends. The water to be purified is introduced at the top, and trickles from tray to tray, becoming heated by the condensation of the steam, and depositing part of its salts of lime on each tray, until it is discharged at the bottom of the apparatus, completely softened, and at a high temperature; so that the heat of the steam employed is not wasted. By opening the front of the case the trays are taken out, from time to time, and cleansed. The practical working of this apparatus is most efficient.

Mr. Siemens' regenerative furnace (United Kingdom—1987) is well known through descriptions which have appeared in the Transactions of the Institution of Mechanical Engineers, and the Reports of the British Association for the Advancement of Science.

Section II.—Land Steam-Engines.

Of the land steam-engines, some are fixed, or semi-fixed, some portable, and some are road locomotives, or "traction-engines."

Amongst the fixed and semi-fixed engines, although a few good examples of beam engines and vertical engines are to be found, the horizontal construction generally prevails; probably owing to the ease and convenience with which all parts are accessible. In some cases, as in the machinery of Messrs. Manlove, Alliott and Co. (United Kingdom—1,924) and Messrs. Whitmore and Son (United Kingdom—2,023), a horizontal engine is used to drive a vertical shaft directly, which is a good arrangement for corn-mills and centrifugal machines.

Many of the steam-engines are employed to drive machinery belonging properly to other classes; and in such cases it is the steam-engine alone that falls under the consideration of the Jury of Class VIII.

In other cases the steam-engine drives some piece of mechanism, such as a hoist, a crane, a pump, a blowing-machine, &c., belonging to a different sub-division of Class VIII., and in such cases any explanation which may be required of the machinery so driven will be found in the proper sub-division of this report.

With respect to the steam-engines in the present Exhibition, as compared with those of 1851, it may be observed that they show an increased employment of high pressure, great expansion, and super-heating, an increased use of surface condensation (generally effected by means of a great number of small horizontal tubes), a tendency towards simplicity in the framing and main moving parts, a general abandonment of devices that are more curious than useful, and a higher perfection of workmanship and finish; all of which improvements combine to produce greater economy of fuel, power, and repairs.

Setting aside merit of a kind that does not require special explanation, such as simplicity, good workmanship, practical success, &c., the following remarks may be made as to those engines which present new and unusual features:—

Manlove, Alliott, and Co. (United Kingdom—1,924) exhibit a pair of horizontal engines, for working centrifugal machines, which are placed with their cylinders bottom to bottom on one frame; so that the tendency to strain the frame, which arises from the inertia of the moving parts, may be balanced by making the pistons move in opposite directions.

The double-cylinder expansive engine, in various modifications, is numerously represented. In the engine of Mr. Wenham (United Kingdom—2,019) the steam is superheated in its passage from the small to the large cylinder (see Section I.) In Messrs. May and Co.'s engine (United Kingdom—1,927) the dead-points are done away with by placing the cranks of the large and small cylinders at right angles to each other; the steam being exhausted from the small cylinder into a wrought-iron reservoir, jacketed with high-pressure steam from the boiler.

In one of the engines exhibited by Carrett, Marshall and Co. (United Kingdom—1,813) the dead point is passed (though its effect is not wholly done away with) by placing the cranks of the small and large cylinders not directly opposite each other, but at a very obtuse angle. (This arrangement has also been employed in Craddock's engine.) The opposite, or nearly opposite motion of the large and small pistons is well known to be favourable to balance of inertia, and also to a good distribution of the steam, by enabling it to pass in the most direct manner from either end of the small cylinder into the adjoining end of the large cylinder. In the drawing of M. Delandtsheer's engine (Belgium—265), the cranks for the large and small cylinders are exactly opposite in direction, and the dead points are done away with by combining a pair of engines with cranks at right angles to each other in the usual way.

The end-to-end double cylinder arrangement is exemplified in the engine of M. Scribe (Belgium—278), and in a model in the United Kingdom division, which is not numbered nor mentioned in the catalogue.*

For producing variable expansion, the system most frequently employed is the ordinary link motion; and next in order as to frequency, the link motion with a separate expansion valve driven by a third eccentric. In Messrs. Ferrabee's engine (United Kingdom—1852) the expansion-valve is driven by a straight-link motion of its own, worked by means of two eccentrics, on a shaft, which is made to turn at double the speed of the engine-shaft by means of a pair of toothed wheels.

In many cases also, and especially in the foreign engines, the variable expansion is produced by means of the compound slide, regulated in some cases by hand, and in others by the governor; and amongst the latter class may be specified the engines of the Magdeburg-Hamburg Steam Navigation Company (Prussia—1,312), the Sprottau Iron Works (Prussia—1,321), Farcot and Co. (France—1,152), C. T. Porter (United States—29). In Messrs. Farcot's engine, the action of the governor upon the variable expansion is very exact and perfect, owing mainly to the construction of the governor, in which, by a peculiar mode of suspension and counterpoise, there is obtained a sufficiently accurate practical approximation to the theoretic accuracy of the parabolic governor, but without its complexity and liability to derangement. (For details, see the report of M. Tresca to the Société d'Encouragement pour l'Industrie Nationale, published in their Bulletin for 1861.) In the governor of Mr. Porter's engine a similar result is obtained by using light balls and a high speed, with a heavy vertical load to balance the great centrifugal force. The figure and movement of the slide-valve in this engine are a peculiar kind, suited to open and close rapidly with a comparatively small travel.

The pumping engines of Mr. Steele (United States—38) and of Mr. Worthington (United States—28) are remarkable as being engines of rapid stroke without fly-wheels. In the former there is a single cylinder, whose slide-valve is moved when the piston is at its dead points, by an apparatus which is in fact equivalent to a small auxiliary steam-cylinder. In the latter there are a pair of equal cylinders, working at half a stroke behind each other, the slide-valve of each cylinder being shifted by the piston of the other.

In M. Schentz's rotatory steam-engine (Sweden—272) the advantages of simplicity and compactness which the rotatory engine is admitted to possess, are combined with the power of working expansively in a very perfect manner; while at the same time the disadvantages of engines of that class are to a great extent overcome; for the pressures at the shaft are balanced, the sliding-valves or pistons are relieved of pressure while they are passing the stops; and the steam-tight bearings, when worn, can all be tightened at one operation, in consequence of the conical form of the casing.

The North Moor Iron Foundry (United Kingdom—1,948) exhibit a steam-turbine, which has been found to work efficiently, and which is convenient for driving fans, the fan and turbine being fixed on the same shaft. Mr. Bourdon (France—1,156) has a turbine driven by a current of water, which is itself driven by a steam jet.

Of the single-acting Cornish engine one example only appears, represented by the model of Messrs. Harvey and Co. (United Kingdom—1,880).

The traction-engines to which awards have been made by this Jury are those exhibited by Bray's Traction Engine Company (United Kingdom—1,805), J. Taylor and Co. (United Kingdom, 2,004), Tuxford and Sons (United Kingdom—2,195). It is well known that, although steam-carriages for common roads are of old date, traction-engines, or road-locomotives, are of recent introduction. All the three engines above mentioned work well in practice.

Mr. Bray's is capable of acting as a portable steam-engine, a steam-crane, or a fire-engine, at will; the rim of each of its two driving-wheels is furnished with blades or spades, which can be pushed out or drawn in, according to the steepness of the road and state of its surface and the load to be drawn, so as to give just the required hold and no more. Messrs. Taylor's is marked by the merit of great simplicity. It has two driving-wheels, six feet in diameter, without blades. Messrs. Tuxford's has a single roller instead of driving-wheels; its engine is well protected against injury by dirt, and the engine-driver and steersman are together.*

Section III.—Marine Steam-engines.

The general remarks as to progress since 1851 which have been made in Section II., as to land engines, are applicable to marine engines also. The improvements in workmanship are even more striking.

A very large number of the marine engines exhibited possess merit of a high order, as this Jury have testified by their awards. They have also indicated briefly in the reasons given for the awards, the particular kind of merit by which each engine is most distinguished.

Of the marine steam-engines, by far the greater number are horizontal screw engines, the reason probably being, that such is the arrangement best suited for ships of war, and that the engines of ships of war can more easily be spared for purposes of exhibition than those of merchant ships.

The horizontal engines are numbered as follows:—United Kingdom, 1,891, 1,902, 1,926, 1,955, 1,964, 2,632 (model), 1,897, 1,962 (model); France, 1,132, 1,195; Sweden, 274. In this form of engine the space is more limited than in any other, and difficulties are thus caused which the skill of the engineer is exerted to overcome in various ways. Hence arise great varieties in the details of the designs of horizontal engines. For example, the engines of Humphrys and Tennant (United Kingdom—1,891) are marked by simplicity and accessibility; the action is direct, the stroke and connecting-rod short, and the cylinder of large diameter. In other examples, a longer stroke and connecting-rod are obtained in various ways: in those of Maudslay, Sons, and Field (United Kingdom—1,926), Ravenhill, Salkeld, and Co. (United Kingdom—1,962), Nouvelle Société des Forges et Chantiers (France—1,195), A. W. Frestadius (Sweden—274), and others, by double piston-rods; in that of E. Nillus (France—1,132) by double piston-rods connected with trunks in the air-pump, a construction which is also used in Britain; in that of G. Rennie and Sons (United Kingdom—1,964) by trunks in the cylinders; in that of J. Penn and Sons (United Kingdom—1,955) by trunks passing completely through the cylinders, &c.

A peculiar arrangement of a duplex horizontal trunk-engine, in which the inside of the trunk is made available as cylinder-space by the aid of a fixed piston, is represented by a model, in the British division of the western annexe, which is not mentioned in the catalogue. (Exhibited by Mr. E. E. Allen.) The engine of M. Frestadius (Sweden—274) has concentric double cylinders.

Amongst oblique screw-engines may be mentioned those shown in the drawings of Armengaud (France—1,181) and of Randolph, Elder, and Co. (United Kingdom—1,960) the latter of which arrived too late to be adjudicated upon).

As examples of the vertical inverted-cylinder screw-engine, so well suited for merchant ships, the engines of Morrison and Co. (United Kingdom—1,936), Tod and M'Gregor (United Kingdom—2,009), and Richardson and Sons (United Kingdom—1,965) may be noticed, as well as a model exhibited by Humphrys and Tennant (United Kingdom—1,891), which will be again mentioned further on. The first three of these have surface condensers, the first two with horizontal, and the third with vertical tubes. The first two are very compact and convenient in their arrangement; the third may be regarded either as a working model or a pair of small engines. The steam, before entering the surface condenser, gives out much of its heat to the feed-water, which traverses a set of tubes surrounded by the exhaust steam.

The engines of Maudslay & Co. are accompanied by a very complete and well-executed set of moving models of marine engines, of a great variety of kinds, both paddle and screw.

The engines of Humphrys & Tennant are accompanied by moving models of themselves, and also of a pair of vertical screw engines, noted for their efficiency and economy in practice, being those of the "Mooltan." These are double-cylindered expansive engines, each small cylinder being directly on the top of its large cylinder.

Paddle engines are represented by working models by Maudslay, Sons, & Field (United Kingdom—1,926), J. Penn & Sons (United Kingdom—1,955), and Ravenhill, Salkeld, & Co. (United Kingdom—1,962), and the drawing of Messrs. R. Napier & Sons (United Kingdom—1,939). The model of Messrs. Ravenhill has feathering paddles and oblique cylinders, while that of Messrs. Penn has oscillating cylinders. The only pair of full-sized paddle engines are exhibited by Messrs. Escher, Wyss, & Co. (Switzerland—104).

The valve gear and expansion gear of the marine engines are very various. For reversing, the link motion is used in almost every case: an exception is found in the engine of the Mediterranean Company above referred to (France—1,195), where the engine is reversed by a piece of wheelwork, which, when acted upon by hand, causes each eccentric to reverse its position on the shaft that carries it. In Humphrys and Ten-

* Exhibited by Mr. E. E. Allen.

* Mr. Yarrow's steam-carriage (United Kingdom—2,033) was included in Class VIII. of the Catalogue, although its place would have more properly been in Class V., (see Jury Directory, page 63). The Jury of Class VIII. examined it, and formed a very favourable opinion of its merit so far as that could be ascertained by mere inspection. They were at first desirous of having its performance practically tested on some road near the Exhibition; but they were induced to desist from considering it further by the belief that it was about to be transferred to the class to which it properly belonged. Unfortunately, that belief was erroneus; and the steam-carriage in question has not been the subject of any award.

nant's engines an improvement in the construction of the link has been carried out, by making it of a single bar embraced by a slider, instead of a pair of bars with a slider between them.

In some examples, the link motion is used for expansive working; but in most the cut-off is effected by means of a separate expansion valve, the mechanism for working which presents a great variety of designs.

Amongst various peculiarities of arrangement, may be noted that of the pair of horizontal screw engines of Messrs. Rennie, in which the cylinders are at opposite sides of the shaft; each cylinder is directly opposite the air-pump of the other; and each cylinder exhausts directly into the condenser by its side, so that exhaust-pipes bridging over the shaft are dispensed with.

The horizontal trunk marine screw-engines of Messrs. Penn, being exhibited by a member of this Jury, could not be made the subject of an award. They are accompanied by a model, already referred to, and by separate parts of engines, showing great perfection of material and workmanship.

Section IV.—Windmills.

The windmill of Wentworth and Jarvis (United States—54) is chiefly remarkable for its regulator, which consists of a pair of slightly diverging vanes forming a sort of tail behind the cap of the windmill, and so connected with the sails, that when the vanes, by the increased impulse of the wind, are pressed closer together, the sails are turned into a position that exposes less surface to the wind.

Section V.—Water-wheels and Turbines.

The conditions to be fulfilled in order that the efficiency of a turbine, or water-wheel of any other kind, may be the greatest possible, are that the water shall begin to act on the wheel without shock, and shall leave it with no more velocity than is necessary in order to prevent the wheel from being choked with back water. All the turbines to which honours have been awarded by this Jury are capable of fulfilling those conditions when properly managed.

Turbines have been classed according to the general direction of the flow by which the water is carried through the wheel, independently of the whirling motion which is first impressed on the water by the guide-blades, and afterwards taken away during the action of the water on the wheel. According to this mode of classification, those of the North Moor Foundry Company, Schiele's (United Kingdom—1,941), and of Fontaine & Brault (France—1,173) are "parallel-flow" turbines, because the general flow of the water is parallel to the axis; and that of Williamson Brothers, Thompson's (United Kingdom—2,026), is an "inward-flow" turbine, because the general flow is towards the axis. In order that the conditions of greatest efficiency may be fulfilled with different loads, the mode of varying the quantity of water supplied ought to be such as to change as little as possible the speed of the whirling component of its motion. This is effected in parallel-flow turbines by supplying the water through a ring of orifices, a greater or less number of which are completely closed when the supply is to be varied, so that all the orifices which are open are fully open. In the inward-flow turbine or "vortex-wheel," the same object is obtained by varying the obliquity of the guide-blades.

The drawing of M. Sagebien (France—1,154) represents a water-wheel which, on theoretical grounds, may be considered advantageous for low falls; but the Jury had not, during their proceedings, sufficient data to enable them to make an award upon it.

Section VI.—Water-pressure Engines.

The water-pressure engines of Sir W. G. Armstrong and Co., (United Kingdom—1,785) are capable of working and standing still at intervals without waste of power or of water. This, in the absence of a reservoir, is effected by the aid of the "accumulator," being a cylinder like that of a hydraulic press, having a plunger loaded according to the pressure to be maintained, and being large enough to contain the store of water which collects when the machinery is at rest, and to supply the surplus of water required when the machinery is moving. One of the engines consists chiefly of a cylinder and piston of long stroke for working a hydraulic crane through pulleys and chain-tackle; another is an engine for producing rotatory motion at high speeds, with three oscillating cylinders, having plungers which act upon three cranks, making angles of 120° with each other. This engine is characterized by the use of "relief clacks;" those are valves which, upon the occurrence of any tendency to excessive increase or diminution of pressure in the cylinder, permit water to flow back from the cylinder into the supply-pipe, or from the discharge-pipe into the cylinder, as the case may be, and thus prevent shocks without wasting water.

Carrett, Marshall, and Co. (United Kingdom—1,813) exhibit a double-acting water-pressure engine specially adapted to the blowing of organs, in which the piston moves with a uniform speed, and there is no fly-wheel.

The water-wheel exhibited by Mr. E. O. Richard (Canada—119) is really a kind of rotatory water-pressure engine.

Section VII.—Vacuum-Power Engine.

The Jury could find no engines to which the above description seemed to be applicable.

Section VIII.—Electro-Magnetic Motive-Power Engines.

Some engines of this kind were exhibited, in which much ingenuity was displayed; but inasmuch as the Jury had no opportunity of ascertaining the convenience and efficiency of those machines while working, either by inspection or from the information of others, they did not conceive themselves warranted in making any award upon them. It is well known that certain electro-magnetic engines are at present in extensive practical use for driving small machinery in which the cost of motive-power is unimportant; but no specimen of those engines was exhibited. The electro-magnetic engine of D. McCallum (United Kingdom—1,916) was carefully searched for, but not found.

Section IX.—Miscellaneous Prime Movers.

The gas-engines of C. W. Siemens (United Kingdom—1,987), and Lenoir and Co. (France—1,188) are driven by the combustion of a mixture of coal-gas and air so proportioned as not to be dangerously explosive; the mixture is fired at each stroke by an electric spark. From the report of M. Tresca on Lenoir's engine, it appears that this engine is not economical of fuel as compared with a steam-engine, but that it is very convenient and useful for driving machinery in situations where a steam-engine cannot be employed. Siemen's engine is provided with a regenerator for saving a great part of the heat which would otherwise be discharged with the waste gasses; and there are theoretical grounds for expecting it to be economical; but precise experimental and practical data as to its economy and efficiency do not yet exist.

The engine of E. B. Neill (United Kingdom—1,943), and the engine in the United States without a number, are both hot-air engines of a kind invented by Captain Ericsson. Those exhibited by C. H. Dennison (United States—32), and that of Schwarzkopf (Prussia—1,319), are also hot-air engines. No advantage in point of economy over the steam-engine is claimed for any of these, their proper use being, like that of the electro-magnetic engine and the gas-engine, to furnish a convenient motive power for small machines where a steam-engine cannot be employed. As the working of these engines within the Exhibition building would have been inconsistent with the regulation which prohibits the lighting of fires in it, the Jury, in order to satisfy themselves that the engines worked in a smooth, steady, and manageable way, obtained from Her Majesty's Commissioners permission for the exhibitors to remove them for a time from the building, and set them to work outside. The results were satisfactory in the case of the two American engines; but the Prussian engine was unfortunately prevented, by accidental circumstances, from being set to work until after the proceedings of the Jury were closed, so that they could not make any award upon it. It was afterwards, however, set to work in the boiler-yard, when it moved smoothly and steadily, and was easily started and stopped. Both the American engines take in at each stroke a fresh supply of air, which is afterwards discharged; Schwarzkopf's engine retains the same air permanently, and transfers it back and forward between the hot and cold end of a receiver alternately.

W. J. Macquorn Rankine,
Reporter.

Subdivision II.—Separate Parts of Machines, Specimens of Workmanship, Miscellaneous Pieces of Mechanism.

Section I.—Heavy Castings or Forgings in the Rough; Castings or Forgings, Plain, Intricate, or Beautiful, in the Rough.

As compared with articles under these heads exhibited in 1851, we consider there is a decided improvement; few, however, are exhibited in this class as abstract specimens, but are for the most part portions of the machines; there are nevertheless some excellent specimens of forgings of very large dimensions, and which owe their excellence in finish and soundness mainly to the facility afforded in their construction by the application of the Nasmyth and other steam hammers; some of the large forged shafts are put together in longitudinal segments, which is another reason for their soundess. A complete revolution in the manufacture of large forgings has been effected by the steam hammer. The castings of large marine engine cylinders and other parts, the crank shafts, cross heads, connecting rods, &c., in wrought iron, as shown in the present Exhibition, are such as never were produced of equally good quality on any former occasion.

Fr. Krupp, Essen (Prussia—1,308).—This exhibition includes the largest block of steel in the Exhibition; also some excellent specimens of cast-steel axle-trees, and other first-rate specimens of steel manufacture. Medal awarded for excellent workmanship and material, practical success, general excellence.

Horder Mining and Forging Company (Prussia—1,258).—Weeel forgings, locomotive tires of puddled steel, wrought-iron telegraph poles, &c. Honourable mention, very good work.

Petrarsa Royal Works (Italy—1,058).—A large wrought iron shaft for screw propeller, very good specimen of plain forging. Honourable mention.

Under the above heads, the Jury wish to call attention to a beautifully-forged and finished cross head for a marine engine, being one of a pair for the "Agincourt," 1,350 horses power; also a connecting rod of similar powers by Messrs. Maudslay, Sons, and Field. The above is not separately designated in the catalogue.

Also to a double-crank shaft for engines of 1,250 horses power by Messrs. Penn and Son, of Greenwich, excellent both as a forging and a finished piece of work, and to the casting of a cylinder which is exhibited in the state in which it left the sand, and without having had any subsequent workmanship bestowed upon it. A most beautiful specimen of loam casting. The above are not separately designated in the catalogue.

Section II.—Specimens of Turning in Metals.

The preliminary remarks of the last section apply with equal force to the different portions of steam-engines and machinery in general, inasmuch as by the improved construction of slide lathes, planing, slotting, and grooving machines, work is produced of the most superior description.

In the construction of all machines and machinery by the best makers, the great aim evidently now is, to introduce such forms as can be obtained by power tools, without the use of the hand-chisel and file, and the result is increased elegance and simplicity, combined with great economy. It is necessary to point out where these results are most striking, as the awards of the Jurors have already shown their appreciation of them.

One specimen alone of turning and finishing in glass is shown, and this is both practical and new.

J. Chedgey, Southwark (U. K.—1820).—Glass-rollers, pumps, and pipes turned and bored.

New manufacture and good work. The only articles of the kind in the Exhibition. Here is exhibited a household mangle with glass bed and rollers. Medal awarded.

Section III.—Specimens in Filing and Finished work in metals, such as Surfaces, Irregular Figures, &c.

Broughton Copper Company, Manchester (U. K.—1,808).—Copper and brass work valves, &c., copper rollers for calico printers, and brass tubes for locomotive engines of very superior quality and workmanship are exhibited by this firm. Medal awarded.

Eadie and Spencer, Glasgow (U. K.—1,843).—Iron tubes for boilers. Medal awarded for good workmanship.

Imperial Iron Tube Company, Birmingham (U. K.—1,894). Metal tubes. Medal awarded for good workmanship.

Newton Keates and Co., Liverpool (U. K.—1,944).—Copper and brass articles for engineers. Medal awarded for good workmanship.

J. Russell and Sons, Wednesbury (U. K.—1,975).—Tubes and fittings, most excellent specimens. Medal awarded for good workmanship.

Stephenson Tube Company, Birmingham (U.K.—1,994).—Seamless metal tubes, rollers, &c. This firm have a most interesting exhibition, and claim great advantages as regards toughness of material from the combination of phosphorous in the manufacture of their metal. The Jurors speak in high terms of the whole exhibition. Medal awarded.

A. Everett and Sons, Birmingham (U. K.—1,848).—Brass, copper, and iron articles, tubes, &c. Honourable mention.

Lloyd & Lloyd (U. K.—1,912).—Wrought-iron tubes and fittings. Honourable mention. Some excellent specimens of workmanship are here exhibited in forgings of wrought-iron junctions for gas, having a great number of outlets on the same piece.

Russell and Co., London and Manchester (U. K.—1,974).—Wrought-iron tubes, &c. Honourable mention.

Section IV.—Valves, Cocks, Pistons, Governors, Driving Bands, &c.

Most excellent articles are exhibited under these heads and by a large number of exhibitors. The valves and cocks are both good in design and constructed of materials well suited to the purpose. Metallic pistons are now exhibited having great facility of accurate adjustment against the sides of the cylinders, so as not to cause more friction than is absolutely necessary for preventing the passage of steam, and of very simple construction, and not liable to derangement. Governors are in great variety, but in most cases they partake of the objections to the ordinary ball and pendulum governor, viz., that they do not give a proportionate amount of steam for a varying load, with a maintenance of uniform speed; still in some cases this desideratum is obtained, and the examples are noted and described under their respective numbers. A decided improvement in driving bands is shown, both as regards materials and mode of construction, in leather, india-rubber, &c.

Valves and Cocks.

Baines and Drake, Glasgow (United Kingdom—1,788).—Engine and boiler mountings. Honourable mention.

J. Beck, Southwark (United Kingdom—1,796).—Valves and cocks. These include some very conveniently arranged angle-placed valves as cocks, and the work and finish are very good. Honourable mention.

E. T. Bellhouse and Co., Manchester (United Kingdom—1,797).—Brass fittings. Honourable mention.

J. J. Silbermann, Paris (France—1,162).—Air-pump valve. Honourable mention.

F. Allen, jun. (United States—29).—As inventor of slide-valves, valve gear, and expansive gear, exhibited by C. T. Porter. By a peculiar arrangement of levers actuating on a slide cut-off valve at the back of the ordinary steam and exhaust valve, a very simple mode of expansion is obtained with great variation. Medal awarded.

S. Leoni, St. Paul's-street, N. (United Kingdom—1,909).—Taps, steam-cocks, bearings for machinery. These have not yet been sufficiently tested to prove their superiority, but appear to to work with little friction. The substance "Adamas" consists of silicate of magnesia, calcined, moulded, and baked to any required shape, and appears to possess peculiar anti-friction properties.

Driving Bands.

North British Rubber Company, Edinburgh (United Kingdom—1,947).—Driving belts, &c. These are said to be very durable, and have more adhesion than leather. Medal awarded for practical utility and success.

C. A. Preller (U. K.—1,959).—Untanned leather driving-belts, &c. In the leather bands made from ordinary leather, where extra strength is required, this is obtained by one or more thicknesses stitched together, which is objectionable, inasmuch as passing over pulleys of small diameter the different layers are at different degrees of tension, and increased wear and friction are the result; this is avoided in a great measure in the driving-bands exhibited by Mr. Preller, who obtains great increased strength by his peculiar manner of preparing the leather, giving extra strength and suppleness, and thus rendering the double strap in most cases unnecessary, and, when actually required, the objection is not so great as with leather prepared in the ordinary way, on account of the thinness and suppleness of the former. Medal awarded for good workmanship and new manufacture.

Webb and Son, Stowmarket (United Kingdom—2,017).—Leather driving-belts, buckets, hose, &c. A very creditable and useful exhibition. Medal awarded for good workmanship.

C. J. Edwards and Son, London (United Kingdom—1,845).—Leather bands, hose, and fire-buckets. Medal awarded for good workmanship.

Hepburn and Sons, Bermondsey (United Kingdom—1,882).—Machine belts and other articles of leather. Honourable mention.

J. Holgate and Co., Southwark (United Kingdom—1,885). — Leather mill-bands and hose-pipes. Honourable mention.

Nobes and Hunter, Borough (United Kingdom—1,945).—Leather bands, hose, buckets, &c. Honourable mention.

W. Potier, Blackfriars-road (United Kingdom—1,957).—Gut wheel-bands. Honourable mention.

M. J. Bleyenheuft, Eupen (Prussia, 1,287a).—Leather machine-straps, buckets, hose, &c. Medal for good workmanship.

J. H. Bleyenheuft (Prussia, 1,287).—Leather machine-straps, cord, hose, &c. Honourable mention.

W. Ruland, Bonn (Prussia, 1,315).—Leather for machine-straps. Honourable mention.

Farcot and Sons, Port St. Owen (France, 1,152).—Governors with crossed arms, arranged so as to overcome in some measure the objection to the ordinary ball-governor, by making it more accurate for varying amount of load upon the engine. Medal awarded.

A. B. Albaret and Co. (France, 1,207).—This consists of a fly-wheel mounted on a movable centre, which enables it to be set at different angles with regard to the line of its own axis; when revolving, the tendency is to move to a position at right angles with its axis, and in so doing to act up the throttle-valve.

Governors.

C. T. Porter (United States—29) exhibits a governor having double elbow arms, the tendency of which is to raise a weight vertically upon the spindle. This governor is very sensitive, and mainly owes it to rapid rotation, which its peculiar construction requires. Mr. Porter also exhibits another governor, particularly applicable for marine engines; this is also a centrifugal ball-governer, but the centrifugal force of the balls is met by a spiral spring, and is thus described by the exhibitor:—"The novel feature in this governor, and that which gives to it its value, is the initial compression of the spring; for example, the spring is compressed two inches by the nut on the spindle. The circle in which the centres of the balls revolve is ten inches in diameter, expanding to one of fifteen inches in diameter. This expanding motion of the balls produces a further compression of the spring of one inch. The balls are shown in the engraving half expanded, and the spring, if released, would be two and a half inches longer than it appears. It will be observed that the expansion of the balls adds fifty per cent. to the diameter of the circle which they at first described, and also fifty per cent. to the original compression of the spring. If, therefore, the centrifugal force of these balls and the resistance of the spring are in equilibrium in any position, they will be so also in every other position, the number of revolutions per minute remaining the same. The resistance varies, by the increase or decrease in the compression, precisely as the force varies by the expansion or contraction of the circle."

M. A. Soul (United Kingdom—1,992) exhibits a governor which may be thus described:—A fly-wheel having a long boss with a spiral groove cut in it, is placed upon a hollow spindle with a straight groove in it; inside said spindle is another which carrres a pin as a driver to the fly-wheel; if the spindle or shaft overrun the fly-wheel, the interior spindle is moved in or out as the case may be, and the movement is communicated to the throttle-valve.

Schiele's governor, exhibited by the North Moor Foundry Company (United Kingdom—1,948), acts by water-pressure upon a piston, given by a centrifugal pump. This governor can be made to exert great force, so as to be capable of acting directly upon the sluice or clow of a water-wheel or other large valve; under ordinary circumstances where great sensitiveness is required, an elastic diaphragm may be used instead of a piston.

J. Hick,
Reporter.

Subdivision III.—Pneumatic Machines.

Section I.—Air-pumps.

These pumps are principally represented by exhausting machines for creating a vacuum for the evaporation of syrups in the manufacture of sugar. They are constructed on a nearly uniform model. Each has a vertical steam cylinder, with beam, connecting-rod, and fly-wheel; the pumps, two or four in number, and made of gun-metal, are placed on either side of the beam. The construction of this kind of machine has been scarcely modified for many years.

We place in this class the exhausters constructed by Messrs. Gargan and Co. (France—1,031), for the drawing of coal gas from the retorts. These machines are represented by excellent drawings by M. Fouché. It is known that in large gas works it is usual, for the prevention of waste, to pump the gas from the retorts, in order that the pressure therein may not be raised above that of the atmosphere, whilst it is delivered into the gasometer with the necessary pressure. Blowing-fans have also been employed with the same object. Messrs. Gargan have constructed exhausting machines with three parallel double-action cylinders, driven by a steam-engine. The employment of these three pumps, which draw from a small regulating gasometer, is sufficient to maintain a very regular current of gas. These machines, which offer a great economy of motive power over blowing-fans, have been adopted by the Gas Company of Paris.

An ingenious instrument of Mr. J. J. Silbermann (France—1,162) was remarked. It is an air-pump for physical and chemical researches. It is furnished with a stop-cock, pierced with several openings, arranged in such a manner that the pump, which is in communication with three receivers, can pump the gas either in or out of

each of the three receivers into the other two at the will of the operator by simply turning a stop-cock.

SECTION II.—BLOWING-FANS.

Among the blowing-fans exhibited may be remarked those of Mr. G. Lloyd (United Kingdom—1,913), and Mr. T. Lemielle (France—1,135). The former was in the Exhibition of 1851. Both in Paris in 1855. The first is composed of blades, the width of which decreases from the centre to the circumference. These blades are contained within two cheeks, forming one body with them, and assuring the complete carrying away of the enclosed air. The absence of lateral leakage accounts no doubt for the comparative noiselessness of the action of the machine.

The blowing-fan of Lemielle, the action of which produces air-chambers of various capacity, acts rather like a piston machine; it continues to furnish excellent results in the ventilation of mines, and it is employed as an air blast in many large works.

The North Moor Foundry Company (United Kingdom—1,941) has exhibited a blowing-fan patented by Messrs. Schiele and William, consisting of a fan having its wings curved and of diminishing width, mounted on the same shaft with a steam turbine, which drives it. This fan is particularly applicable to the ventilation of steam and sailing vessels.

The Vienna Imperial and Royal Commission for the Ventilation of Military Hospitals (Austria—630) exhibits a ventilating fan of Dr. Heger. This instrument consists of a wheel, having the same axis as the tube which encloses it, and having blades inclined to this axis, it will be evident that the rotary movement of the blades sets in motion the air within the tube. The variable sections of the tube and of the openings for the passage of the air are arranged in a manner to diminish as much as possible the loss of motive power.

From the reports furnished, this machine appears to have attained a useful effect of 55 per cent. of the power employed, which is considerable for a ventilator.

SECTION III.—BLAST ENGINES FOR FURNACES, ETC.

The blast engines exhibited are very few. The vertical beam engine continues to be preferred in England. A blast engine of very fine workmanship is exhibited by the Lilleshall Company (United Kingdom—1,910).

A double horizontal engine on the system of W. Fossey, is exhibited by M. L. Pérard (Belgium—273). The admission and expulsion of the air take place through circular slides placed at the bottom of the blowing cylinders, which are pierced with sixteen openings radiating from the centre; the slides have similar openings. In turning round their centre the slides open and close simultaneously all the openings in the bottom of the cylinders; thus is obtained a large area for the admission of air with a slow movement of the valve, which only makes one turn for sixteen made by the machine. During the period of the delivery of air, the pressure on the slides is in a great measure compensated by the pressure of the air circulating in a false bottom, which prevents the separation which would be produced in spite of the guides between the slides and the bottom of the cylinders. At a speed of seventy turns per minute, this machine can deliver 150 cubic metres of air, at a pressure of eight or ten inches of mercury. Like the blast engine of Messrs. Laurens and Thomas, this machine is free from the shocks of the valves, notwithstanding the great speed of the pistons, but it presents over its predecessor these advantages, viz., that the speed of the slides is low, and that the pressure on the different parts is balanced, and from this reason they are not so likely to get out of order.

Mr. Holmgren (Sweden—269) has exhibited a model of a blowing-machine of three single-acting vertical blowing cylinders; the driving shaft is placed below, and the connecting rod is composed of four diverging pieces of wood directly attached to the piston. The different positions of the piston are not parallel with each other; if it were replaced by a sphere of the same diameter as the cylinder, it would have an action theoretically as perfect as that of a cylindrical piston. To profit by this property there has been provided for the piston a spherical fitting, and the connecting rod lengthened as much as possible to diminish the extent of the oscillations of the piston.

Mons. J. Schaller (Austria—561) exhibits forge bellows, and a portable forge with double-acting bellows of a cylindrical form, and enclosed in a square case of sheet iron, having on the upper part the fireplace and a small hood.

SECTION IV.—MISCELLANEOUS.

Under this head are arranged a certain number of machines belonging to the Class VIII., but which it is difficult to distribute in the different sections of the class as defined by the Jury Directory. In the first place is the apparatus of Dr. Normanby (United Kingdom—1,946), for the production of fresh water from sea water. The water is distilled by the steam from the boilers of the steam ship, or from a special boiler in sailing ships.

The apparatus is disposed in such a way as to retain along with the steam from the evaporated water all the air previously dissolved in this water and in that which is employed in condensation, which in the upper part of the condenser nearly reaches the boiling point. This total quantity of air exceeds that which fresh water can hold in solution, so that the condensation produces water perfectly aërated. The empyreumatic taste occasioned by the distillation has still to be got rid of, and this, it appears, is successfully accomplished by filtration through wood charcoal. The whole apparatus is simply and practically disposed; the evaporation is entirely self-acting, requiring only the regulating of some stop-cocks.

The machines for the manufacture of aërated waters are very numerous, and are generally well constructed. It could hardly be otherwise with the manufacturing machinery required by an industry which becomes daily more extended.

M. Heckmann (Prussia—1,303) has exhibited an evaporating pan of large dimensions, for the boiling of sugar in vacuo, 3 metres diameter, and 3·60 metres high, and of very good workmanship.

M. F. Legal (France—1,157) has sent the model of a similar sugar vacuum pan, with some peculiar modifications to avoid the carrying over of sugar with the steam.

Subdivision IV.—Hydraulic Machines, Cranes, &c.

SECTION I.—HYDRAULIC MACHINES, PUMPS, AND FIRE-ENGINES.*

The different systems of pumps are represented in great number. Among the chain-pumps may be remarked that of Mr. J. U. Bastier (United Kingdom—1,792), formed by a series of circular pistons in caoutchouc, moving in a tube of iron enamelled on the inside. To avoid friction the pistons have a diameter somewhat smaller than that of the tube, which itself is slightly narrowed at the lower part, sufficient to allow the pistons to pass with slight friction, thus preventing all loss of water. This apparatus is easily fixed; but we think, nevertheless, that the other pumps would be preferred for great quantities of water, or for great depths.

Murray's chain-pump, exhibited by Mr. Middleton (United Kingdom — 1,930), formed of plates of wood firmly connected together with iron chains, and moving in a rectangular case or trunk, is easily set up for temporary drainage purposes.

The force and lift pumps are in great variety; a large number of constructors have sought to give to the water-ways and valves dimensions which render as small as possible the loss of power by friction. They have also sought to give a continuous movement to the ascending column of water, independently of the action of the reservoir of air. This result is obtained in the pump of Messrs. Carrett, Marshall and Co. (United Kingdom—1,813). The solid piston is worked by a rod of half the section of the piston itself; during the up-stroke the upper surface forces a volume of water into the ascending column, and the lower surface draws in twice that volume. In the down-stroke these two volumes are sent into the receptacle communicating with the upper surface of the piston. One of the volumes here fills the space which would otherwise be left empty; by the descent of the piston the other volume is sent into the rising tube. These pumps, which are of small size, are only exhibited as donkey pumps, for the continuous feeding of steam boilers with water.

The uniform movement of the water is obtained in a still more simple manner in the pump of Messrs. Farcot and Sons (France—1,152), in which two equal pistons with valves affording very large waterways, work parallel to each other in two pump cylinders. During the successive strokes the first piston draws in water by its upper surface, and delivers it to the ascending column by causing it to traverse the second piston. In its ascending course the second piston raises in its turn the column of water by its upper face, whilst the lower face sucks the water, causing it to traverse the first piston. This pump has yielded all the good results promised by its ingenious construction, and it is adopted in the water supply of Paris.

M. Letestu (France—1,167) exhibits pumps which are already very well known, as well as a double pump of large dimensions for drainage purposes. It is chiefly in operations where the waters are charged with mud or gravel that the pumps of M. Letestu have been found most useful.

The pump of Messrs. Knowelden and Co. (United Kingdom—1,901) has the general disposition of a fine engine pump, but between the extremity of the piston and the valves is a diaphragm; the free space between the piston and this membrane is filled with water covered with a layer of oil, so that the greasing of the piston is always perfect, and no sort of liquid nor foreign body can interrupt the action of the piston. The four valves, inlet and outlet, are arranged on the same bed plate, and can be easily visited and repaired. Their grouping presents this advantage, that by turning the bed plate this pump acts in the opposite sense, and can thus easily cleanse the ascending tube from any foreign bodies which have happened to get in, as they are very apt to do.

M. Perreaux (France—1,142) exhibits valvular pistons in caoutchouc. The piston is in one piece, and hollow below, and terminated in the upper part by two thin lips, generally closed, and so much the more effectually as the pressure above is greater, but which open to leave a passage for the water from below as soon as the pressure on this side predominates. With this piston, and a similar piece forming a bottom valve, a pump is obtained of a very simple construction. It is necessary to remark, however, that the repairs of the pistons in the generality of cases cannot be easy, and that the resistance of the material at the opening, and the small dimensions of the orifices, require an excess of motive power which would become of importance in pumps of any but of small dimensions.

The centrifugal pumps are chiefly represented by the systems of Appold and Gwynne. The first, constructed by Messrs. Easton, Amos, and Sons, obtained a very remarkable success in the first universal Exhibition of 1851. The second, very inferior at that time as regards the successful employment of motive power, has been so well modified, that in the absence of comparative trials, it would be difficult to decide to which of these two machines the preference should be given, for they offer no essential difference except in the position of the axis of the wheel, which is vertical in the first and horizontal in the second. We believe that this system of pumps will receive numerous applications by the ease with which it can be set up, and its working without shock; by the employment of a steam-engine at a high rate of speed, which would be easy of

* The report on the fire-engines is drawn up by the Special Jury on that subject. See Appendix to the Report of Class VIII., page 14.

transport and readily fixed; it is well fitted for employment in large temporary drainage works.

We would mention also for simplicity of arrangement of the different parts, the drainage pump of Mr. Goodwin (United Kingdom—1,862), and the double-acting pump of Mr. Hansbrow, (United States—40), and the double-acting pump of M. Hubert (France—1,200), which furnish the French fountains in the grounds of the Horticultural Society.

Steam Pumps.

Messrs. Harvey and Co. (United Kingdom—1,880), employed in more than half of the waterworks of London, have exhibited a model of one of their large single-acting steam pumps, imitated from the drainage pumps of the Cornish mines. They are now adopted in nearly all large towns. The comparative experiment which will shortly be made at Paris between this system and that of Messrs. Farcot and Son (France—1,152) will therefore be highly interesting. It is useful to remember that in the Cornish engines, even in those used for the drainage of mines, where the mass in movement is more considerable, the action of the steam valve has never been so perfect as desirable. The diameter of the piston has always been too large to allow of the admission of steam at the pressure in the boiler (30 to 45 lbs.) without causing a detrimental velocity; there arises a throttling effect which absorbs a great part of the available work.

A great number of steam feed pumps are to be found at the Exhibition, all with steam and water pistons on the same piston rod, sometimes vertical, but more often horizontal.

Two pumps may be seen from the United States, Mr. H. Steel (39), and Mr. Worthington (28). They are without fly-wheels; one of them has only one steam cylinder and one pump; the slide valve is brought into action instantaneously at each stroke of the piston by means of a small supplementary steam piston very ingeniously disposed. The other pump is composed of two cylinders of each kind; the steam slide valve is guided in each machine by the piston-rod of the other; by this means the movements are simultaneous in opposite directions with perfect regularity.

To mention Giffard's injectors, exhibited by Messrs. Sharp, Stewart, and Co. (United Kingdom—1,299), Flaud (France—1,164), is to record their success. They are found at the Exhibition universally amongst the principal industrial nations, thus showing how this invention has been appreciated.

Professor Colladon (Switzerland—106) is the inventor of a water-wheel to be set in motion by large streams of water, and constructed on the most scientific principles. It is at present used for the raising of water; between two exterior cylindrical surfaces exists a spiral partition in which the water stands at the level of the axis, and can be raised to a height commensurate with the number of the spirals.

Messrs. Wentworth and Jarvis (United States—54) exhibit a windmill for the raising of water; self-regulating when the force of the wind increases; the guide sails close in, and increase the obliquity of the angle formed by the motor-sails, with the direction of the wind.

There has also been placed in Class VIII. a well-arranged machine for washing and bleaching of tissues, exhibited by Messrs. Sulzer Brothers (Switzerland—112), and a machine for washing linen by Mr. Parker (United States—89).

Water Rams.

The different hydraulic rams exhibit no new arrangement, with the exception of that of Messrs. Bollée and Son (France—1,165), by the adoption of a clack valve analogous to double-seated valves. He diminishes considerably the intensity of the shock; the pump feeding the air reservoir set in movement by the play of the ram, but always situated above the level of the highest waters, works even whilst the ram is under water, which allows it to be placed in such a manner as to profit by all the height of the fall. Finally, the valve is counterpoised at will by a regulator, by means of which the velocity of the machine is governed. There is here a manifest progress which should render the use of this machine more frequent.

Hydraulic Presses.

Among the hydraulic presses exhibited there are some in which it has been sought to perfect the movement of the pumps; we may mention that of Messrs. Peel, Williams, and Peel (United Kingdom—1,954), in which the two pumps of different diameters work together. Both work in the usual way up to a pressure determined beforehand; when the effect of the large pump ceases the small pump works alone to the point fixed for the maximum pressure to be obtained, and when its play ceases to have any effect. This modification of the working of pumps is obtained by the very ingenious arrangement of two safety valves acting on the same lever, so that when the pressure reaches the first fixed limit, a valve is raised and gives to the lever a slight movement which causes the water to be driven into the cistern instead of the press; at the second limit another supply valve, raising the former fulcrum of the lever, annihilates in its turn in the same way the action of the small pump. As soon as the pressure descends below the second or the first limit, the small pump, and then the large one, recommence their effective work.

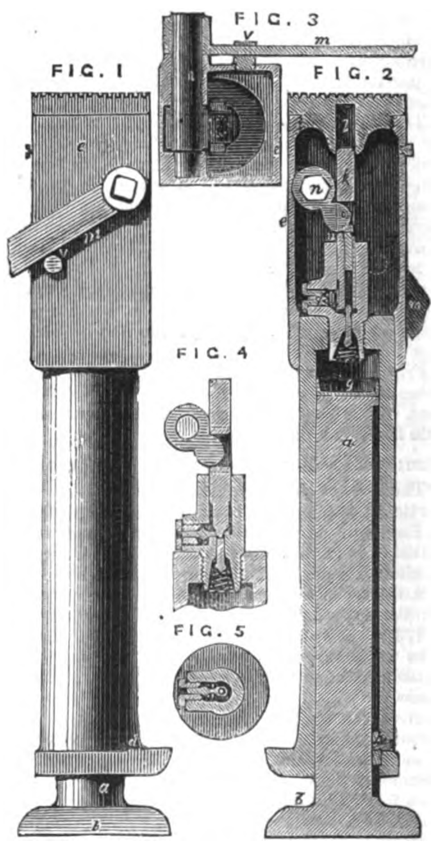
Mr. F. O. Ward (United Kingdom—2,015), has sought simplification of another kind. On a hollow bed, serving also as a cistern, he groups a horizontal steam-engine and pumps, thus compressing two machines into the space of one. The pumps are peculiarly constructed to avoid accumulation of air. They are also of thrice the usual length, and coupled in pairs by a novel arrangement, allowing all four to be driven by two connecting rods—a considerable economy. That their threefold length may not involve diminished directness of thrust, the connecting rods are proportionately lengthened. Thus twelve pumps with their twelve sets of valves are replaced by four, and twelve connecting rods, with their costly fittings, by two. This cheapened construction implies less cost of maintenance, fewer working parts and reciprocating motions, fewer valve beats and less "back slip." The power is transmitted by pinion and spur wheel, geared to afford suitable leverage and suitable relative velocity of the steam and water in motion. These are all points of advantage, but it would seem desirable to isolate the steam cylinder from the cistern, in order to avoid refrigeration.

To be continued.

TANGYE'S HYDRAULIC LIFTING JACKS.

Mr. J. Tangye, of Birmingham, has recently patented an improvement in hydraulic lifting jacks, which consists in constructing and arranging the parts.

Fig. 1 of the above engravings represents in elevation a hydraulic jack, made according to this invention. Fig. 2 represents a vertical section; and Fig. 3 represents a horizontal section of the same. The ram *a* of the jack is solid, and made in one piece with or fixed upon the foot *b*. The cylinder is made of solid steel or other metal, and works upon the said ram *a*, rising and falling thereon. It has a claw *d* at its bottom, whereby lift from the ground can be had when required. On the top of the cylinder the reservoir *e*, containing the water or oil, or other liquid with which the jack is worked, is situated. The pump is situated within the reservoir *e*, and the cylinder, reservoir *e*, and pump therein rise together. A liquid-tight joint is made between the cylinder and ram *a*, by means of the cupped packing *g* on the top of the said ram, as represented in Fig. 2. A slot is cut in the ram *a*, in which slot a key *h* secured to the cylinder by a screw slide, the key prevents the cylinder from turning upon the ram when weight is applied. The pump is screwed into the top of the cylinder as represented; *k* is the plunger of the pump, the upper end of which plunger works in the hole *l*, in the upper end or cover of the reservoir *e*. The plunger is worked by the hand-lever *m* fitted on the end of the shaft or axis *n*. The shaft has a tongue or cam, which works in an opening in the plunger, and by its motion actuates the pump, and thereby raises or lowers the plunger. The liquid from the reservoir *e* is conveyed to the cylinder so as to raise the jack, and returned from the cylinder to the reservoir so as to lower the jack in the following manner:—The inlet valve *q* of the pump is fitted on a small brass seat, and the valve case containing the valve is screwed into the side of the pump near the bottom of the cylinder. The valve *q* is kept to its seat by a helical spring. The valve *s* is situated in the axis of the pump, and in a line with the plunger *k*, this valve being kept to its seat by another helical spring. By working the hand-lever *m*, the plunger is raised and lowered in the pump through the cam or tongue and shaft, and the liquid from the reservoir *e* is forced into the cylinder, and the cylinder and parts carried by it raised. On the side of the reservoir a pin *v* is situated, the object of the pin being to limit the descent of the hand-lever *m* during the raising of the jack. The liquid in



the cylinder is returned to the reservoir when the jack is required to be lowered, by means of the lowering valve *u*. The lowering valve is situated and works in the hollow of the plunger *k*, and is kept to its seat by the downward pressure of the tongue or cam, the edge of the tongue or cam pressing on the top of the said valve so long as the hand-lever *m* is not depressed below the pin *v*. When, however, it is required to lower the jack, the hand-lever *m* is shifted on the shaft or axis *n*, so as to clear on its descent the pin or stop *v*, and be enabled to take the position represented in Fig. 2. When the lever *m* is brought into the last described position, the edge of the cam or tongue no longer presses upon the valve *u*, and that valve is raised from its seat by the pressure underneath it, and forced into a slot formed in the end of the cam. At the same time the lower end of the plunger *k* forces the outlet valve *s* from off its seat, and the liquid from the cylinder passes through the valves *s* and *u* to the reservoir *e*, and thereby lowers the jack.

Fig. 4 represents in vertical section another

arrangement for opening the valves so as to lower the jack; and Fig. 5 is a horizontal section of the same. In this arrangement a third or lowering valve, as described and represented in Fig. 2, is dispensed with. The inlet and outlet valves are arranged similarly to those before described; but one of the valves has an elongated stem or head, with a hole in the centre thereof. The bottom end of the plunger is contracted as represented. On depressing the handlever *m* below the stop pin *v*, as before explained, in order to lower the jack, the contracted end of the plunger passes through the hole in the head of the valve, and withdraws it, and at the same time strikes against the other valve, and forces it from its seat. The water ways of the valves are thereby opened, and the liquid from the cylinder returns through the said waterways to the reservoir, and thus lowers the jack.

KING AND VARVILL'S FLUSHING APPARATUS.

Messrs. King and Varvill, of Liverpool, have recently patented an invention for an apparatus for flushing closets, as illustrated in the above engravings, which they describe as follows:—

This invention relates to the apparatus immediately in connection with the cistern obtaining the flushing fluids, and though applicable to all cisterns, is especially so in large towns where a

FIG. 2.

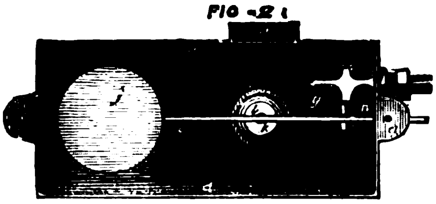


FIG. 1.

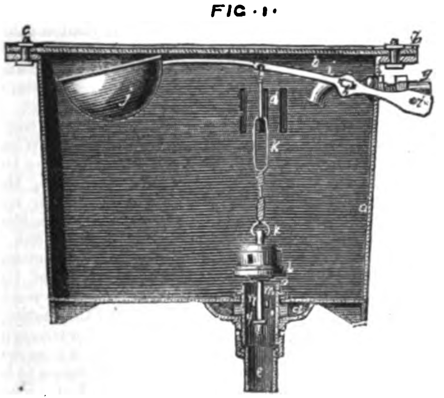


small or intermediate cistern is supplied from the street mains, or from a cistern at an elevation, the object being to prevent the waste of the flushing fluids.

To the ordinary connections of the hand lift or pressure seat arrangements, we joint or otherwise connect a lever, which is carried into the cistern, and balanced or supported on the end of the horizontal plug or barrel of a tap fitted to the supply pipe. On the other end of this lever is affixed the float, and between the said tap and float is attached a chain or lever which reaches to, or near to, the bottom of the cistern, and operates the out-flow or flushing valve. The overflow pipe is cast with the cistern and communicates with the flushing or waste pipe in the usual way.

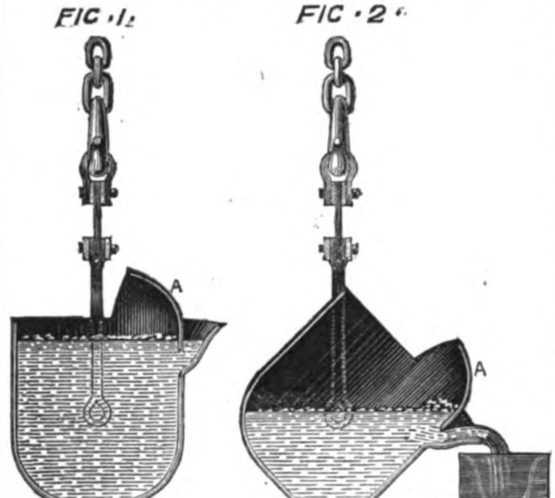
By this arrangement it will be seen that when the part of the lever outside the cistern is acted on, the float will be raised, the supply tap shut, and the out-flow or flushing valve opened; but as soon as the lift or pressure seat is left at freedom the float falls and opens the supply tap, until such time as the cistern is again filled; thus preventing more than the quantity contained in the cistern from being used by one movement.

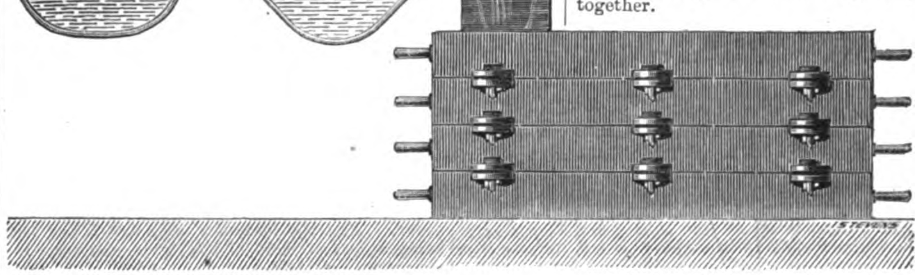
Fig. 1 is a section of one of our improved apparatus with, or as part of, a small or intermediate cistern; and Fig. 2 is a plain view of the same apparatus with the cover or lid removed. *A* represents the cistern, which may be conveniently placed on a shelf or in a recess in the wall of a house or other building, the opening or mouth being closed or covered by a lid *b* fastened by bolts and nuts *c*; *d* the water or flushing fluid overflow passage, it may be cast, or otherwise formed as part of the cistern, the lower end of which said passage or way communicates with the out-flow or flushing pipe *e* by the opening *f*; *g* the water or fluid supply tap, the pipe connection for which may be led directly from the street mains or from another cistern at a greater elevation; *h* the plug of the tap to which the combined float and operating lever *i* is attached. At or near to one end of this lever there is an aperture or other means of connection, to which the hand lift pull, or other arrangement of closet apparatus, is made fast, and if the coupling or jointing gear consist of another lever, say in the usual vertical position, then it must have a slot or its equivalent therein, to allow the lever *i* to be operated by the float for filling the cistern; we prefer, however, to make the connection by a chain or rope. At or near the other end of the lever is the float *j*; *k* is a wire chain attached to the lever *i*, and to the out-flow valve *l*, which latter has a guide *m* passing through the straps *n* to bring the said valve properly to its seating *o*. The lever *i* is depressed at the outer end, consequently the float *j*, the wire chain *k*, and valve *l*, are raised into position to allow the water or other flushing fluid to escape by the pipe *e* to the closet. When the chain is released, the float *j* will descend by its own weight, open the supply tap, and admit water or other fluid to the cistern for the next flushing. The opening in the plug of the tap when one of the ordinary construction is used, or the passage in the tap of whatever kind employed, must be so arrangedthat when the lever is acted on sufficiently to open the valve *l*, the supply must be shut off, otherwise the great economy of flushing fluid effected by our apparatus would be frustrated, for the lever *i* might be moved, the valve *l* opened, and the flushing fluid might flow from the supply tap *g* through the cistern *a* by the pipe *e* in a continuous stream. As before stated, the only quantity of flushing fluid that can be obtained by one movement of the pull or other arrangement is that contained in the cistern.

The Duke of Luynes has just transferred to the French State, by deed of gift, his magnificent collection of antiques, marbles, bronzes, and medals, which he has passed his life in putting together.

AN IMPROVED FOUNDRY LADLE.

FIG. 1. FIG. 2.





The engravings show an improved foundry ladle, lately invented by Mr. John Phillips, the foreman of the iron foundry at Messrs. Maudslay, Sons, and Field, and which has been tried in their foundry with great success. The object of the improvement is to prevent the necessity of skimming the metal by hand when pouring it, as is now usually done. This is accomplished by fixing a curtain plate at the mouth of the ladle, which projects downwards into it so as at all times to be below the surface of the metal when in the act of pouring. This plate effectually skims the metal, and allows only a stream of pure metal from below to run into the mould. Fig 1 shows a ladle fitted with the curtain plate A, and fig. 2 shows the same when pouring the metal.

Another experiment was tried in the same establishment with a ladle with a central hole through the bottom fitted with a plug, as practised by Mr. Bessemer in running his converted metal into the moulds. This experiment was also successful, and the plan will be of great service in running large castings, as it effectually prevents any of the scoria from getting into the mould, and also saves the labour and the risk of turning up the large ladles, as hitherto practised.

Scientific Jottings.—M. Em. Monnier recommends the following method for dyeing wood of a rose colour by chemical precipitation:—A bath A is prepared with 80 grammes of iodide of potassium per litre of water, and a bath B in another vessel with 25 grammes of bi-chloride of mercury. The wood to be dyed is first put into the bath A, where it is left for several hours; it is then dipped into the bath B, when it assumes a beautiful rose colour. The wood thus dyed is afterwards varnished; the baths will last a long while without any necessity for renewal. M. Payen recommends the following cure for diseased trees and shrubs:—As soon as it is perceived that the leaves are turning yellow the earth must be dug up all round the root within the space of a metre and a half from the stem, and the roots are then watered, twice on the first and once on the following day, with a solution of 525 grammes of sulphate of iron, 500 of common salt, and 525 of alum, in 40 litres of water. This treatment will instil fresh vigour into the sound roots, corrode the bad ones, and restore the health to those which were about to be attacked. The amalgam of sodium as an agent for reducing metals is beginning to attract attention. Mr. Ch. W. Vincent has obtained an amalgam of chromium by introducing that of sodium into a solution of chloride of chromium, and by subsequent distillation in a retort filled with naptha vapour the chrominm itself is obtained in a finely divided state. Mr. W. B. Giles also has decomposed a saturated solution of pure protochloride of manganese by the amalgam of sodium, whereby an amalgam of manganese was obtained. The mercury of the latter being driven off by the application of heat, there remains a brownish black powder, which appears to be manganese.

DEFLECTING ARMOUR FOR SHIPS.

FIG. 1.

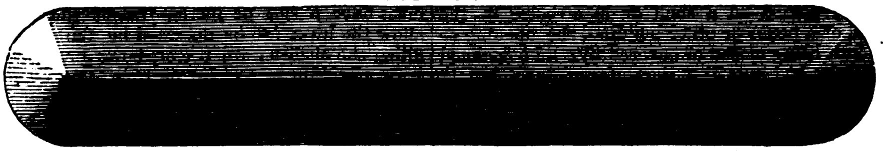


FIG. 2.

FIG. 3.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

SIR,—In a recent number of your valuable magazine, I read with much interest a description of deflective armour for ships of war proposed by Mr. Richardson. As far as its deflective powers are concerned, it might, no doubt, answer its intended purpose, but as to the construction of his shields he appears to have fallen into a great error.

I will call your attention to those parts in it which seem so defective, and for the sake of better illustrating my meaning, I refer to the drawing you gave. Mr. Richardson there points out the action of shot when striking upon these conical shields, but only in two different points, and these two on the surface of the shield; everyone will of course admit that the shot would be deflected from these two points; but a shot coming full force from a gun's mouth is not confined to these two particular points; it is quite as likely to strike it in a much more dangerous part than this, and I would ask Mr. R. what would be the consequence if it struck it in that part where the three conical shields meet (as seen in fig. 1 of his drawing)? Would it be deflected then? I trow not! but severe results, it is to be feared, would follow, and worse still, such as could not be easily repaired, for I believe that such a structure, made as strong as modern science will permit of, must inevitably yield when submitted to the action of such ordnance as we are now able to produce.

There is no doubt but that a system of deflective armour might answer very well if the world were confined to the use of spherical or elongated projectiles with round heads; these would naturally glance off; but, I ask, would a punch or square-headed shot do so? Would not its sharp edge tell uncomfortably upon the conical shield? For let it be struck at whatever angle it is possible to do from an opposing ship, by a shot such as the last mentioned, it must to some extent be injured, especially if it be not very thick; and from recent experiments there is every reason to believe that such projectiles will come into use. These last remarks seem to be the great objection to deflective armour.

For my own part I cannot see why Mr. R. proposes a series of these conical shields, for in such a structure there are so many places where a shot striking must naturally commit serious destruction—I mean at the junction of these cones or shields.

Undoubtedly a great amount of good might be obtained from using armour that would deflect shot, but it must be constructed differently to the one proposed, and in a form that would answer the purpose better. I refer to the diagrams hereunto annexed, of which fig. 1 is a front elevation, fig. 2 a plan, and fig. 3 an end view, of a shield for deflecting shot, proposed to be attached to the sides of a vessel of iron; the shield is intended to extend the whole length of the unprotected portion of the ship, and to any extent that experience will prove best below the water line.

On referring to the diagrams it will be seen that the shield has the same sectional form as Mr. Richardson's, but differing in this respect, that the same form is continued in one continuous length along the ship's side, possessing the advantages of uniform strength and shape, not having any point in it where, being struck, it is more likely to yield than at any other; a shot striking at any point on this shield would be deflected; but as I have before said, those square or punch-headed shot must punish it severely, of whatever form it may be. Here lies the difficulty of rendering ships' armour unyielding to such terrible opponents. In submitting this form I do not suggest any mode of fastening such a shield, but the shape of it only. I trust that Mr. Richardson will not accuse me of having picked his invention in too many pieces, but as he very truly remarks in the early part of his letter, "that he considered the duty of every artillery engineer officer to produce guns that will be able to crush these plates," so I considered it my duty to point out what appeared defective in his armour, trusting it may tend to elicit some truth on the subject, and that you will kindly allow space for these remarks in your columns.

I am, Sir, yours very faithfully,
ST. JOHN VINCENT DAY.

Newton Abbot, 1st October, 1862.

THE WAVE LINE THEORY.

SIR,—Mr. Quart asks you for a short space to "contradict" my statement regarding the yacht "America's" load line. He then quotes that statement, but does *not* contradict it. Rather strange this. Mr. Quart appears to deem it preposterous in me to suppose that the wave line is applied by its advocates as the plane of flotation. In yachts, be it observed, this plane may be considered constant, with regard to its distance from the lower part of the keel. He says, "Just as if the load water line is to be a wave line." Well, is it not a *sine qua non* with wave line theorists that this should be so? I think it is. Mr. Quart must enquire as to this. But what does he mean by saying, "perhaps, Nauticus would like the deck line to be a wave line?" Now, seeing that I have argued for concave lines about and at a moderate distance above the gripe, for convex lines about the surface of the water, and for buoyancy above, I can only characterize this remark of Mr. Quart as foolish, if not worse. The "bow and stem of the 'America' are both perfect wave bodies." Such is the *ipse dixit* of my censor. But we are discussing the wave *line* theory, not the wave *body* theory. And the idea of a stem and a bow both being a perfect body of the same character! I cannot understand it.

Mr. Quart proceeds, "if Nauticus will try about 6 ft. below the load line, he will find as beautiful a wave of translation and a wave of oscillation as possibly can be constructed." Now these two great pearls are worth diving for. Let us try.

I take the drawing of the "America" and observe, as is well known, that her keel is curvilinear, rounding up considerably forward. At 6 ft. aft from the front of the stem, at the load line, occurs my first vertical sectional line; at that line the rabbet of the keel is only 3 ft. 2 in. under water. At 5 ft. further aft it is about 4 ft. 8 in. under water. At 5 ft. still further aft it is about 5 ft. 6 in. under water, and at 5 ft. further aft still the rabbet of the keel is 6 ft. under water. Now, having gone 21 ft. aft in a vessel about 90 ft. long without finding any portion of the vessel's body so deep as 6 ft., I must give up as hopeless the two treasures which Mr. Quart has held out to delude me.

Mr. Quart's last sentence is, "Nauticus would alter his opinion about Mr. Scott Russell's wave line if he only knew how to apply it." For this read, "if he only knew how to apply it *with advantage*," and I at once shake hands with Mr. Quart.

NAUTICUS.

[We have received several other letters on the wave line controversy, including a long one from Mr. Moy, but we think our readers will agree with us in thinking that enough has been said, for the time, on the subject. We beg, however, to thank our numerous correspondents for their interesting and instructive letters.—ED. M.M.]

NEW JETTY, DEVONPORT DOCKYARD.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

SIR,—In your paper of the 3rd October you are pleased to speak favourably of this important work. I am gratified it meets with your approval; but there is one error in your notice which I should desire to correct. You say it was designed by me; this is not so. With the merits of the design, which I think very good, I have nothing to do. This credit belongs to the Director of Works Department, at Somerset House. I have only endeavoured to give effect to his design, by executing the works for the Board of Admiralty in the best possible manner, and if the quality of my work be approved of I am satisfied,

I am, Sir,
Yours most respectfully,
HENRY GRISSELL.

Meetings for the Week.

Civil and Mechanical Engineers' Society.—On Setting out Railway Works, by G. J. C. Dawson, at 7·30 p.m.

Gossip.

At present the iron-shipbuilding works of Messrs. Laird, Brothers, and Co., at Birkenhead, present a very animated spectacle, upwards of 3,500 men being employed there on various vessels, amongst them the monster iron-clad frigate "Agincourt," 6250 tons, for the royal navy—the construction of the ship herself, the new dock in which she is being built, and the shed which covers it, all proceeding simultaneously; the screw troopship "Orontes," a noble-looking craft, of 3,008 tons, also for the royal navy, and intended to be launched about the end of November; two iron-clad shell-proof rams, of very peculiar shape and construction, rising into shape under the shed where the famous "290" was put together, and the paddle steamer "St. Columba," built some years ago as a Holyhead express boat, and now lengthened 40 feet and converted into a boat for carrying cattle for the City of Dublin Steam-packet Company.

RANSOMES AND SIMS' CROSSING.—In a letter addressed to one of our contemporaries, allusion is made to Ransome's and Sims' patent chilled cast-iron crossings; and the assertion is made that similar crossings have been in use on the Stockton and Darlington railway for above 25 years. It appears, however, to be a misapprehension on the part of the writer to suppose that Ransomes and Sims claim a chilled cast-iron crossing as new. What they seem to claim is the mode of manufacture. On reference to the patent, No. 853, year 1856, the claim will be seen to be as follows:—"I do not claim generally the making of railway crossings, either in part or entirely, of cast-iron; but what I claim as my invention is the making of railway crossings, when of cast-iron, with those portions of the wing rails which are subject to the greatest wear, of harder cast-iron than the other part of the casting, and using in combination therewith a steel or wrought iron point, so connected as to be capable of removal and renewal." Whenever invented, this seems to be a very excellent and durable crossing, and any iron-founder will know that it must be very cheap to manufacture. There are three different exhibitors of these crossings in the western annexe of the International Exhibition; one being the firm of Ransomes and Sims; the second Herr Ganz, of Buda, Austria; the third being the Maschinenbau-action, Gesellschaft, of Cologne, in the Zollverein division. The latter firm shows some broken pieces of this kind of crossing in a glass case, in order to make us English fully understand the advantages of chilling the wearing part of a casting! It is possible that the Prussians of Cologne believe themselves to be the original inventors of this as of most other things. It is well known that they refused Monsieur Gifford a patent for his injector, on account of want of novelty. They showed, however, some appreciation of it, as soon afterwards a law was made forbidding any boiler in the Prussian dominions to be without it. Their brasswork manufacturers offer to put the injector on to English portable engines to be imported into Prussia. They give us a reason for accepting the offer—that they can do it cheaply, having no royalty to pay!

A correspondent in a letter on railway accidents, says:—"The question is, can anything be done to prevent or diminish such accidents? I answer unhesitatingly, yes; and the way, and the only true way, is the most thorough and perfect system of brakes, which should be in the control of the engine-driver or guard throughout the entire train

No vehicle should run in a passenger train, nor should any carriage be considered complete without a perfect brake of power enough to stop the wheels. The momentum of a train at forty or fifty miles per hour is something enormous; it exists at every point of the train, and can only be arrested promptly by brakes. This power may not be, and perhaps is not, needed for the ordinary purposes of traffic, but still no train should run without this safe-guard. Anchors, extra spars, lifeboats, pumps, life-preservers, &c., &c., are not needed for the ordinary purposes of a ship, but no passenger ship is considered complete without these precautions. Hundreds of inventions have been made for this purpose, demonstrating that trains can be stopped in a fourth the distance that they usually are. Why, then, are they not adopted? Is it on account of the cost? Surely that should not be an objection. Suppose it should cost £20,000 for any of our leading companies to arrange its entire stock with such a precaution, that would be £4,000 a-year for five years, and it is not possible for the same amount of money to produce such an amount of safety in any other way. It could run its trains every three minutes, without a signal on its line, with more safety than they now can with the best of signals."

The annual meeting of the Association of Assistant-Engineers took place at Glasgow on Tuesday night, in the Religious Institution rooms, when the report of last session was read by the secretary and adopted. The meeting then proceeded to the election of office-bearers, when Mr. W. R. Copland was re-elected president, and Mr. William Foulis, 3, Holmhead-street, secretary. A paper was announced for next meeting, "On the Slide Valve," by Mr. W. Foulis.

A locomotive mail-clad battery has been constructed at Jackson, Tennesse. It is constructed upon a platform car thirty feet long by eight wide. The sides and ends are of 2½-inch oak plank, upon which boiler iron is riveted. The sides lean inward sufficient to glance a ball upward; one end is perpendicular, and the other pitched to a sharp angle. In the centre of the car is the circle upon which the gun-carriage revolves, and the whole arrangements of the gun are designed with reference to counteracting the recoil at the firing. A 6-inch James rifle cannon is mounted so as to sweep in every direction, and it has been tested with shell. It is designed to protect trains against guerrillas.

THE ORIGIN OF PETROLEUM.—The Canadian *Journal of Art* asserts that Canadian petroleum is not derived from coal, nor is it of recent origin. It says:—"Petroleum was formed long before the coal, and is the result of the decomposition, under pressure, of an infinite number of oil-yielding animals which swarmed in the seas of the Devonian period, long anterior to the coal. The decomposition of marine plants may have given some oil to the rocks of Canada and the United States, which are saturated with this curious substance. The shale beds of Collingwood furnish an answer to those who object to the infinite number of animals it would require to produce the oil locked up in the earth. Those shale beds are composed altogether of the remains of Trilobites—they extend from Lake Huron to Lake Ontario, and far west and east of these lakes. The oil-bearing rocks of Canada were once a vast coral reef, extending from the Gulf of Mexico to Lake Superior. There is the best ground for belief that the supply of oil will last for a long period, and that new discoveries will be made in different localities."

The death of Mr. James Walker, C.E., took place on the 8th inst., at Great George-st., Westminster. The lamented gentleman was in his 81st year, and although his demise occurred somewhat suddenly, it cannot be said that it was premature. Mr. Walker had enjoyed an exceedingly prosperious professional career, and his name is indissolubly connected with very many great civil-engineering works in all parts of the world. No doubt the most prominent of these will be referred to in the biographical sketch of Mr. Walker which will be read at an early meeting of the Institution of Civil Engineers, of which eminent body he was elected president on several occasions. Mr. Walker's history affords another illustration of the sure success which waits on perseverance and energy; for he originally came to London in the capacity of a journeyman millwright, and he, probably, dies a millionaire.

"A gentleman," says the *Scientific American*, "who has spent some days in the region of the coal oil wells, in Pennsylvania, says that in his opinion the Government of the United States ought to interfere at once, and put a stop to further pumping and boring for oil on this continent. He is quite certain the oil is being drawn through these wells from the bearings of the earth's axis, and that the earth will cease to turn when the lubrication ceases! Such a suspension would beat anything that ever agitated Wall-street, and the consequences be too great for ordinary minds to conceive or comprehend. It should be attended to at once."

ALLOYS OF ALUMINIUM.—Two alloys of this metal have been manufactured at Newcastle, viz., copper 95, aluminium 5; and copper 92½ to 7½ of aluminium, and called by those working them aluminium bronze. We have examined both proportions, and give preference to the 7½ per cent., especially for colour. The hardness appears quite equal to the best brass, while the colour is that of rich gold; it takes a high polish, and appears to work soundly. We recommend experiments with this latter, namely, 7½ aluminium bronze, to our readers, and suggest that particular attention be paid to the effect of atmospheric moisture with varying temperatures, as it is represented not to tarnish. If such be the case, its employment for the frames of watches and chronometers might save much labour and expense.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

THE Abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following Table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved, and combined with all the advantages of a division into classes. It should be understood that these abridgements are prepared exclusively for this Magazine from official copies supplied by the Government, and are therefore the property of the Proprietors of this Magazine. Other Papers are hereby warned not to produce them without an acknowledgement:—

STEAM ENGINES, 769, 776, 788, 819, 833.
BOILERS AND FURNACES, 786, 814, 831.
ROADS AND VEHICLES, 784, 799, 809, 839.
SHIPS AND BOATS, 762, 770, 774, 820.
CULTIVATION OF THE SOIL, 773, 836.
FOOD AND BEVERAGES, 760, 802, 813, 822.
FIBROUS FABRICS, 790, 791, 793, 797, 816, 817, 818, 842.

760. R. A. BROOMAN. *Improvements in the manufacture of barytes and barytic products, and the application of these substances in the manufacture of sugar and other uses.* (A communication.) Dated March 18, 1862.

In carrying out this invention the inventor takes carbonate of barytes and treats it according to the processes known as those of Messrs. Dubrunfaut and Leplay, that is to say, he pulverizes carbonate of barytes, mixes it with powdered coal, and calcines it in a reverberatory furnace. After having been subjected to heat for from about five to six hours, a product is obtained composed of caustic barytes, coal, and ash, known as raw barytes. This composition is cooled out of contact with the air; it is afterwards lixiviated, and a solution of barytes is obtained adapted to effect the precipitation of sugar. The caustic solutions are first desulphurized by hydrated oxide of iron, or by hydrated oxide of zinc; they are then concentrated in iron vessels, heated by the gases from the reverberatory furnaces, or otherwise. When the solutions have acquired the greatest density of which they are capable without forming a deposit, they are removed to iron vessels similar to those used in the manufacture of caustic potash and soda. The caustic barytes is reduced in these vessels to the state of dissolved hydrate with one equivalent of water; it is next run into iron pots in blocks easy to carry. The inventor states that this economical method of preparing barytes will enable it to be sold at so low a price that its use will spread for many purposes. The hydrate may be used in sugar refineries for precipitating the treacle, and the carbonates may be returned by the refiners to the manufacturers to reduce. The processes above described for natural carbonate of barytes apply to artificial carbonates of barytes, and the hydrates of barytes may be manufactured by means of sulphate. For that purpose he reduces in a furnace sulphate of barytes mixed with coal, exactly as above stated for the treatment of the carbonate of barytes. He thus obtains raw sulphuret, which, by washing, yields solutions of sulphuret of barium. These solutions, treated by a current of carbonic acid, yield carbonate of barytes, which is transformed into hydrate by the processes above described. Sulphuret of barium may be used in excess to precipitate sugar; then the sugar of barytes and the mother waters treated by carbonic acid will yield carbonate of barytes, which may be treated according to the processes hereinbefore described to obtain the hydrate. *Patent completed.*

761. J. T. BUCK. *Improvements in instruments and work cases known as "Ladies' Companions."* Dated March 18, 1862.

In constructing and fitting up these cases the inventor takes a wedge-shaped case, similar to those now used as scissor cases, and fits therein compartments for containing, behind each other, pairs of scissors, of different sizes. He then inserts a wedge-shaped slide behind the scissor compartment for carrying a knife, eyelet piercer, nail trimmer, or other articles, according to taste. This slide may carry articles both at front and at back, or at front only, and a looking-glass may be attached to the back; or the looking-glass may be made to form a separate slide by itself. At the back, again, of the before-named articles he inserts a wedge-shaped folded thread and needle carrier, and on the inside of the flap which folds over to close the case he attaches a thimble carrier, pin-cushion, and needle cases. *Patent abandoned.*

762. A. KRUPP. *Certain improvements in the method of manufacturing shafts for steamboats and other purposes.* Dated March 19, 1862.

This invention has relation to the construction of shafts for steamboats and other purposes, whereby the inventor is enabled to form large shafts of two or more parts, coupling the same together, as follows:—He forms on the end or ends of each portion of the shaft a flange, in the centre of which, and corresponding with the centre of the shaft, is a projection or a hollow, as the case may be, the projection in one end of the shaft fitting into the hollow in the end of the contiguous portion of the shaft. The two flanges on the two ends of two portions of the shaft, when brought together, should exactly fit, and there is formed round the circumference of the flanges (one half being in each) a rib. The flanges are bolted together with strong bolts and nuts, or rivets. He cuts into the flanges two, three, or more key-ways, radiating towards the centre of the shaft, and fits into these key-ways correspondingly-shaped keys. The key-ways should be so cut as that half the thickness should be in each flange. When these keys are inserted he takes a hoop of the same width as the two flanges when combined. This hoop is divided into two or more parts, and placed round the circumference of the flanges, the inside of the hoop having a groove or recess corresponding with the rib on the circumference of the flanges. This hoop may be in one piece, if thought desirable, in which case the hoop must be expanded by heat till sufficient to pass over the rib on the flanges. He then shrinks on the outside of this hoop a steel or iron ring, which tends to bind the whole more securely together. By this arrangement he is enabled to form crank shafts in two or more pieces, coupled together, having two or more cranks, and of larger dimensions than can conveniently or economically be forged in one piece. *Patent abandoned.*

763. R. HADFIELD and J. SHIPMAN. *Improvements in hardening and tempering wire and crinoline steel.* Dated March 19, 1862.

This furnace is constructed with fire-clay tiles or slabs, or metallic slabs having holes or longitudinal channels, through which the wire steel is drawn. These slabs, made of such sizes, and with as many holes or channels as may be required, form the covering of the firing places; the heat passes from beneath them through apertures in each angle of the furnace, along the top surface to the central outlet flue, through which its passage is regulated by a damper in the usual manner. In close proximity to the outlet end of the furnace is placed an open cold water trough, partially immersed in a vessel containing a hardening composition of tallow, resin, and whale, or other suitable oil, mixed in the proportion of about one pound of tallow and one pound of resin to one gallon of oil. The vessel containing the hardening composition is immersed wholly in another vessel, into which water from each end of the open trough is continually flowing, the waste water passing off through outlets in the angles. The steel is drawn beneath the cold water trough through the hardening fluid, and thence through clips between leather or other material, to remove partially the oil, &c., adhering to it. Being thus hardened, it is tempered by being drawn beneath a roller through molten lead, heated to a proper temperature, in an open vessel. The rolls which regulate the motion of the steel, and draw it through the furnace and troughs, are adapted for drawing as many strings or strips of steel, or wire, as may be required, of different widths, thicknesses, or gauges. The lower roll is in one length, but for each string there is an independent upper roll, which can be adjusted by springs and screws to the size of the steel passing beneath it. Before being wound on the swift or reel, which receives the steel on completion of the process of hardening and tempering, a considerable length is exposed to the action of the atmosphere, in order that the necessary cooling and consequent contraction of each string may take place. *Patent completed.*

764. S. DESBOROUGH. *Improvements in the manufacture or construction of sewing or other needles.* Dated March 19, 1862.

The needles manufactured according to this invention are formed by preference with an additional eye or eyes near the head of the needle, through which the sewing thread is passed, after passing through the ordinary eye of the needle, by which arrangement the thread will be prevented from drawing out so readily as is the case with needles of the ordinary construction. *Patent abandoned.*

765. R. WILSON. *Improvements in hydraulic presses, and in machinery or apparatus for raising or forcing fluids.* Dated March 19, 1862.

This invention consists in applying three or more cylinders and rams to the same hydraulic press, whereby the pressure can be regulated according to the resistance to be overcome. *Patent completed.*

766. S. Moore. *Certain improvements in machinery for compressing and cutting tobacco.* Dated March 19, 1862.

These improvements are applicable to those machines in which the tobacco is continuously supplied, compressed, and cut, and they consist in giving the requisite intermittent advancing motion to the cutting or "play boards" by a screw, the cutting boards being formed in detachable parts, each of which is carried forward towards the cutting knife by means of a driver, furnished with one or more parts of nuts gearing into the screw. The cutting boards bear upon, and are firmly supported by, a fixed or adjustable iron bed, furnished with grooves by which the drivers are guided. *Patent completed.*

767. R. A. Brooman. *Improvements in printing and painting upon glass and ceramic wares, and upon metallic and mineral substances; also in the preparation of inks and colours for printing and painting.* (A communication.) Dated March 19, 1862.

This invention consists in methods of printing or painting upon glass, ceramic ware, stone, metal, and other surfaces, directly, or indirectly, by means of what the inventor terms reserves, as well as in the preparation and use of colouring matters and inks suitable for this particular class of printing, and for other purposes. First,—Impression upon glass or ceramic ware: This part of the invention comprises four processes:—1. Impression by transfer of reserves soluble in liquids or destructible by fire, and figuring in relief upon the glass the lines and outlines of the design transferred. A design being given, previously engraved upon wood, stone, or metal, it is printed upon paper in fatty ink, according to the means now followed for such purpose. This design is transferred to glass, and constitutes the reverse; then by a pencil or brush the inventor applies the metallic silicates or oxides, which, after firing, are to show the impression. In order that these oxides, silicates, or metallic colours, may adhere to the glass, and at the same time be insoluble in solvents of resinous and fatty bodies, which compose the fatty inks, the oxides, colours, or silicates, are mixed up with a solution of gum, dextrine, or other similar organic substance impressible and capable of adhering to glass, and are desiccated; the fatty reserve is next dissolved, either in sulphuret of carbon or in hydrocarbons, or other similar solvents which will not have the effect of dissolving gum, dextrine, or other analogous organic substances. The vitrifiable oxides and metallic colours held upon the glass by bodies insoluble in liquids in which the fatty reserves become dissolved, remain fixed upon the glass, and are subjected in muffles to the fire; they vitrify and form the lines and outlines of the design to be reproduced.—2. This second process, which is the counterpart of the first, differs only that the printing of the reserve is effected in thin inks; the vitrifiable oxides or metallic colours are fixed and applied in the hollows and interstices of the reserve with fatty or resinous bodies insoluble in water, whence it follows that, the reserve being soluble in water, he attains, by simply reversing the substances employed, a similar end to that arrived at by the process first described.—3. The third process consists in taking a design previously engraved on stone, wood, or metal, in printing it upon paper in a fatty ink containing combined with it oxides, carbonates, alumino-silicates, or alkalino-terrous sulphates, earthy or metallic, and little or not at all vitrifiable at the temperature at which glass fuses. The design printed upon paper in the said ink is transferred to glass, and forms the reserve; in the hollows and interstices of this reserve he applies, either in a damp or in a dry state, vitrifiable metallic oxides or colours, which are intended to reproduce the design printed. Firing then takes place, the articles are allowed to cool, after which, the non-vitrifiable bodies which have acted as the reserve are removed with a brush, by hand, or by acids.—4. The fourth process is the counterpart of the third in that the reserve is printed in thin ink instead of in a fatty ink. The invention also comprises processes for the preparation of the inks and colours employed. *Patent completed.*

768. R. A. Brooman. *Improvements in reproducing or in producing copies of guipure laces, embroidery, and other like articles.* (A communication.) Dared March 19, 1862.

This invention consists in means (which cannot be described here in detail) of producing, without the aid of engraver or draughtsman, stereo-plates of all designs or patterns, which possess or are capable of offering a relief, such as guipure, embroidery, lace, and the like. The process followed consists, in principle, in making the object to be reproduced serve itself for its own re-production. *Patent completed.*

769. R. A. Brooman. *Improvements in rotary engines.* (A communication.) Dated March 19, 1862.

This invention consists in a movable piston sliding in a mortised shaft, tangent to the interior surface of an ellipsoidal cylinder, which piston is in constant contact at its ends with the inner surface of the said cylinder. Metal packings, kept up by springs, are fitted to the ends and sides of the piston, as also to that part of the shaft through which the piston slides. At the sides where the shaft enters and leaves the cylinder it is made conical, and a correspondingly-shaped collar is pressed into contact therewith by springs in order to ensure a steam-tight joint. By reversing the inlet and the outlet the shaft can be made to revolve in either direction. A lubricating passage at the top of the cylinder, fitted with taps, admits lubricating matter into the cylinder, and passages are also provided for lubricating the conical parts of the shaft. The engine is worked by steam, air, or any other gas. *Patent completed.*

770. R. A. Brooman. *Improvements in apparatuses for drawing in and paying out chain cables, applicable to windlasses and capstans.* (A communication.) Dated March 19, 1862.

In carrying out this invention, catches, free to rise and fall in guides, under the action of levers, are placed round the internal circumference of the frame of the apparatus, the number of catches being regulated according to the size of the apparatus or the size of the chain to be worked. These levers are mounted on the same axis as longer levers, which extend outside the apparatus and terminate in rings. When heaving in, handspikes are inserted in the rings; and as the apparatus is thereby caused to revolve, the catches become raised as they approach the chain and act upon it. *Patent completed.*

771. J. Cumming. *Improvements in the method of and apparatus for distributing and setting-up type.* Dated March 19, 1862.

This relates, 1st, to a novel method of distributing type that has been used for printing, and for arranging the letters or type in order in columns suitable for being placed in the composing machine, which forms the second part of this invention. The distribution or arranging of the type in columns is accomplished in the following manner:—Marks or nicks are cast out or planed by preference on the back of the types, but these nicks may be made in any convenient part of the type. By making these nicks long or short, and arranging them at different parts of the type, as great a number of combinations may be produced as will be required for different letters. A sharp edged rule is made to pass the whole length of a line of types, and this edge is inserted into these nicks. Another similar rule is applied in the same way at the same part of the type, or in another nick, and by causing these rules to approach or recede from one another, the type will be separated into the different characters. A nick is left at each end of the types for the purpose of drawing the letters from one another by force, after they have been partially separated. By means of this composing machine, which forms the 2nd part of the invention, the types are set up and formed into words or sentences by selecting or taking single letters. This selecting is effected by keys arranged on a kind of scale-board, and by depressing these keys the letters are forced out of the groove (in which the columns of letters are placed) into a line or channel running along the machine. The letters during this operation are held in their proper position by a box covered with leather, or other suitable material, on one side, for the purpose of forming a friction-pad to hold the types in their proper position till another instrument or part of the machine comes into operation to collect all such of the types as may be thrown up out of their grooves by the keys above-mentioned. *Patent abandoned.*

772. G. M. Todd. *The improvement of the sewing machine in such a manner that it shall form a new stitch, which he entitles the "tie-knot stitch.* Dated March 19, 1862.

This relates to shuttle machines, and consists in the formation of a new stitch in the following manner:—The needle carrying a thread passes down through the material to be sewn, and forms a loop, through which the shuttle (also carrying a thread) passes horizontally; the shuttle then passes over its own thread, which may be either in proceeding to, from, or in returning to its original position. The two threads when drawn up in proper tension by the motions of the shuttle, and the needle will form the tie-knot stitch. *Patent abandoned.*

773. B. Samuelson. *Improvements in chain harrows.* Dated March 20, 1862.

The patentee has found that the operation of chain harrowing can be more efficiently performed than hitherto, by causing those links which stand vertically, or a portion of them to present an angular or cutting edge. He effects this by bending the iron or steel of which the links are made, so as to present an angle towards the front; and he prefers to make the links out of iron or steel of a triangular section, but so that the apex of the triangle shall be towards the outside, and the base inside. It is not necessary that all the links should be bent or made to this form, but those whose planes are vertical and parallel to the line of draught. *Patent completed.*

774. J. G. T. Campbell. *Certain implements in ships' propellers.* Dated March 20, 1862.

This invention is not described apart from the drawings. *Patent abandoned.*

775. A. Hill. *An improved fastening for stays.* Dated March 20, 1862.

This fastening applies to those stays which are fastened in front, and consists of two parts; one a stud formed with an enlarged head, that is, a head of greater diameter than the shaft which carries it, is fitted to one of the busks or ends of the stay. The other part of the fastening is fixed to the other busk or other end of the stay, and consists of a button free to revolve upon a pin, and made with a metal shell on the under side thereof, formed with a circular slot, and with an enlarged aperture at the entrance into the slot. The fastening is effected by passing the enlarged aperture on the shell of the button over the stud; and by then turning the button to bring the slot over the head thereof, which being too large to pass through, the slot is retained in it. To unfasten, turn the button in the reverse direction until the enlarged aperture comes over the stud, when it willescape, and the two parts will become separated. *Patent completed.*

776. R. M. Roberts. *Improvements in obtaining and applying motive power.* Dated March 20, 1862.

This consists in using a weighted wheel, the weight being placed at a given point of the circumference thereof (or only a projecting lever or radius weighted at its end), such wheel or lever, or radius, having affixed to the axis or shaft thereof, and turning therewith an eccentric, so set on the axis that the rim of the eccentric shall always be nearest to the weight on the wheel (or lever, or radius aforesaid). This eccentric is to be arranged so as to continuously work into an eccentric opposite thereto, fixed in manner as aforesaid on the axis of another and similar weighted wheel, or lever, or radius. The two wheels and eccentrics so arranged cause the weights to traverse a portion of the circle, the one weight pulling opposite to the other; and, in order to traverse the other part of the circle two, four, or more precisely similar weighted wheels or levers and radii and eccentrics, working in conjunction as aforesaid, are connected by wheel gearing; for instance, with the aforesaid arrangement of weighted wheels, or levers, or radii and eccentrics. *Patent abandoned.*

777. E. Smith. *Improvements in means or apparatus for cutting stone, wood, and other material, which improvements are also applicable to modelling in plastic material.* Dated March 20, 1862.

The object here is, mainly, to give facility for obtaining copies of works of art, though the improvements are applicable to other productions. For this purpose, the tracing point for tracing over the surface or surfaces to be copied is supported at one end of a bar or frame, the other end of which carries a rotating or other suitable cutter for cutting into the material to be operated upon to produce the desired copy. The tracer and the cutter are held horizontally, or somewhat in that direction, by their bar or frame, which is capable of adjustment in a rod or frame, which, whilst suspended upon hinge joints from above, inclines somewhat from a vertical line, with a tendency to exert pressure, which pressure may be aided by a weight or by the hand of the operator regulating the amount of force exerted. The material to be operated upon is either placed upon a bed capable of rotating upon a vertical axis during the cutting action, so as to cut around it, or on a bed capable of moving in various directions. By varying the position of the cutting, or scraping instrument, in relation to the tracing instrument, and the axis or axes of motion of the carrier, an enlargement or reduction of the article copied may be obtained. *Patent completed.*

778. E. Field. *Improvements in regulating the flow of gaseous and other fluids.* Dated March 20, 1862.

This consists in causing the fluid the velocity of which is to be regulated to pass into a chamber, from which its exit must take place through or around a movable piston, diaphragm, plate, or leaf connected or formed with or attached to another piston, diaphragm, plate, or leaf, so that any variation in the velocity of the passing fluid, by acting upon one or other of the pistons, diaphragms, plates, or levers, shall cause the other to proportionately open or close the opening by which the fluid passes through the regulator. *Patent completed.*

779. W. Baddeley. *An improved method of preparing tobacco for smoking, and in the apparatus to be used for that purpose.* (A communication.) Dated March 20, 1862.

Here the tobacco leaves being moistened, are formed into rolls by hand, which rolls are passed between graduated ground rollers, which compress them, giving the required form and solidity. The roll thus formed is passed through a tube, in which it receives a glutinous coating, after which it is bound round with a thread or band, and then dried. When sufficiently dry it is fit for smoking in pipes. *Patent abandoned.*

780. W. Clark. *Improvements in the manufacture of soap.* (A communication.) Dated March 20, 1862.

This relates to making soft potash soap, or hard soda soap, with a sulphurous base, which soap may be used with advantage in all the ordinary applications of soap, especially for diseases of the skin. By the term sulphurous base the inventor simply wishes to imply that sulphurous matters are mixed with the ordinary soaps. *Patent abandoned.*

781. G. T. Bousfield. *Improvements in pianofortes, organs, harmoniums, and other instruments having keyboards.* Dated March 20, 1862.

This consists in the application to such instruments of an enharmonic scale, that is, a series of 41 sounds in each octave or settine, which will give in just intonation every major and minor scale in a series progressing upwards by fifths from C flat through C natural to C sharp, or from 7 flats through C natural to 7 sharps, to adapt the signatures generally used in music with the chromatic and enharmonic scale of each. Also in the application to such instruments of a key-board shifted by pedals, by which one is enabled to perform in any of the above scales at will (by shifting the board to the proper position), while one is using the fingering of the easiest scale, viz., C natural major and A natural minor. There are peculiarities in the way in which the keys are jointed and kept in their places. *Patent abandoned.*

782. D. E. Siebe. *Improvements in machinery or apparatus for refrigerating or producing cold, part of which improvements are applicable to other purposes.* Dated March 21, 1862.

The patentee claims, actuating the valves of air pumps by cams or other equivalent means, such cams being brought into action so as to open the valves at varying periods, corresponding with the requirements of the pressure in the pump for the time being of the air or other elastic fluid operated upon. 2. The arrangement of condensers wherein the current of condensing water is caused to flow in a direction contrary to that of the vapour to be condensed, and is kept throughout its course in intimate contact with the pipes, tubes, or chambers containing the vapour, substantially as described. 3. The construction of refrigerators with vertical tubes, as described. 4. The general arrangement and combination of parts constituting a regulator, as described. 5. The arrangement described for moving the ice-moulds successively upward towards the refrigerating power. *Patent completed.*

783. R. Kay. *Certain improvements in the method of printing calico and other surfaces, and in apparatus connected therewith.* Dated March 21, 1862.

This consists in the use of surface rollers constructed as follows:—The bed or internal portion of the roller or cylinder is composed of metal, and fits on to the ordinary mandril; such internal cylinder is to be covered or coated with gutta-percha, paper, papier-maché, india-rubber, vulcanite, plaster of Paris, glue, hide, or other substance not subject to injurious contraction and expansion, and which will give sufficient support to the delineating wire or type metal casting used to define the edges of the pattern. This gutta-percha or other materials is removed when the design is outlined for the india-rubber surface to be inlaid.

When the design is outlined with the valve or type, and the exterior cut away as usual, the portion within the wire is also to be removed, and the excavation or intervals filled with india-rubber or gutta-percha, in place of felt (as sometimes similarly employed), the surface of the india-rubber being previously grooved parallel to the length of the rollers to retain the colouring matter. By this means the method of printing surfaces is improved, inasmuch as the grooved india-rubber yields its colouring matter more freely than wood or felt, and from its own elasticity yields to the pressure without forcing the colour too deeply into the cloth, and clearer and more perfect impressions are obtained. *Patent completed.*

784. W. J. CURTIS. *An apparatus to ascertain and point out the fares and earnings or receipts of public vehicles and their conductors.* Dated March 21, 1862.

One mode of carrying out this invention consists in connecting a wheel or the wheels of a carriage with a dial or indicator, by an endless chain passing round the nave of a wheel, and also over a pulley fixed to a shaft working the indicator; or any other mode of connection may be adopted. This dial shows to the passengers the space the carriage passes over. Connected with the dial may be a cylinder or box, containing a column of cards or tickets, which will move in exact agreement with the dial, the movement of which stops when the carriage stops. A punch, forming part of the machine, nicks or marks the tickets in exact correspondence with the dial, when given to the passenger by the conductor on entering the carriage, and it may be again marked in uniformity with the dial when the passenger leaves the carriage, thus showing the fare to be paid. *Patent abandoned.*

785. J. NEWALL. *Improvements in supplying gas to railway carriages, stations, steamboats, and other vessels, omnibuses, or other carriages, at any required pressure.* Dated March 21, 1862.

Here the patentee uses a vessel or cylinder of any convenient shape and dimensions to compress gas by water, or rather liquids, previous to its being conveyed to its distination for use. To the said vessel or cylinder he attaches a water gauge, a gas feed pipe for supplying the same, another pipe for supplying the compartments or places, a water gauge, a water exit pipe, and a supply pipe for conveying the water into the said vessel to compress the gas. He first fills the cylinder with water from high-pressure water pipes to drive out the atmosphere, or any impure air. He then opens the water exit valve or tap to let the water out, and then admits gas into the vessel or cylinder to supply the partial vacuum created by the exit of the water. When the water is nearly all run out, and the vessel or cylinder is full of gas, he closes both the exit valve or tap, and also the gas valve or tap. To compress the gas, he then admits water at any necessary pressure, which may be supplied from different sources—as an elevated tank or reservoir, street water mains, force pumps, or other means. When he has compressed the gas into the vessel or cylinder, he passes it into a holder fixed in part of a carriage compartment, cabin, or place required, and he then applies valves or apparatus to reduce the gas from high pressure to any ordinary burning pressure that may be required, either for heating or lighting purposes. For warming or heating railway carriages or other places, he places a small cylinder, or other shaped vessel, in a part of the carriage, compartment, cabin, or other required place, and fixes a jet or burner inside thereof, to be lit when necessary; the heat from the said small vessel with the burning gas inside will warm the room or compartment where so placed. *Patent completed.*

786. J. M. HART. *Improvements in means of generating steam.* Dated March 21, 1862.

Here the steam is first generated in a boiler of any form. The steam is then conducted into superheating pipes or chambers of a form and structure suited to the boiler to which it is arranged. While the steam passes from the boiler to the engine, or other apparatus wherein high steam is required, it must of necessity come in contact with the heated surface of the superheating pipes, which are made of cast or wrought iron or copper; the metal in the heated state absorbs oxygen from the steam, and becomes oxydized, hence a rapid destruction of the material ensues. To prevent this, they fill the superheating pipes or chambers with a granulated material broken into suitable sizes, or of a moulded material moulded into such forms as will expose the greatest amount of transmitting surface, composed of either earthy, metallic, or the ores of metals, or of carbonaceous compounds, either animal, vegetable, or mineral, or of any material which will take up heat from the superheating pipes and again readily transmit it to the steam as it comes into contact with its surface; at the same time, the same material will absorb oxygen. *Patent completed.*

787. J. FAWCETT. *Improvements in the manufacture of soap, particularly applicable to the scouring, cleansing, and fulling of woollen or other cloths.* Dated March 21, 1862.

The patentee claims the application, use, and addition of the jelly produced from lichen or moss, to alkalis and oily or fatty matters, in order to manufacture soap. *Patent completed.*

788. J. HUMPHRYS. *Improvements in steam-engines.* Dated March 21, 1862.

The first part of this invention consists of a novel description of slide-valve, applicable to such engines, whereby with great simplicity of construction considerable economy is effected in the transmission of the steam from the high pressure to the low pressure cylinder. The valve is a treble-ported slide-valve; the laps at the extreme ends of the valve cut off from and supply to the small cylinder the high pressure steam from the boiler. The steam, after having acted on the piston of the small cylinder, is conveyed through a passage, forming part of the valve, into the large cylinder, which it enters and leaves for the condenser by the inner portion of the valve, which portion is an ordinary double-ported slide-valve. The second part of the invention consists of improvements in the arrangement of the parts of compound engines, whereby great simplicity and accessibility are obtained. These engines may be vertical or placed at any angle with the horizon, but arranged horizontally. They are particularly adapted for driving the screw. The small cylinder for the high pressure steam is placed within the large cylinder, so that the outer piston is an annulus; this annulus has two rods, and the small piston has one rod; these three rods are attached to a crosshead working in guides forming part of the main A frames of the engine. From this crosshead a connecting rod with a wide fork at the crosshead end is attached to the crank pin. The eccentrics and their rods for working the slides are placed outside the outer bearing of the crank shaft. *Patent completed.*

789. B. H. MATHEU. *Improvements in fire-arms and in cartridges.* Dated March 21, 1862.

This invention relates to large and small arms and ordnance, and comprises—first, a new arrangement of parts for breech-loading arms; second, a new method of rifling arms; third, an improved back sight for arms; fourth, an improved cartridge for breech-loading arms. The patentee constructs his breech-loading arms as hereafter explained. At the rear end of an ordinary barrel he forms a longitudinal aperture, and at the back of that aperture he forms a transverse cylindrical hole for the reception of a curvilinear wedge. The longitudinal aperture is filled and covered by a solid plunger, the face of which bears against the end of the barrel proper; the rear end of the plunger is formed with a hollow curve to receive the curvilinear surface of the wedge. The curvilinear wedge is furnished on one side with a projection which forms a crank, the pin of which is inserted in a slot of a side lever, the fore end of which is attached to the fore part of the plunger or barrel, while the back end terminates in a handle for opening and closing the breech. The improved cartridge to be used with the breech before described consists in forming the case with a flange projecting from the rear, and with a tail carried from the flange, in the end of which a percussion cap is inserted. For other than the system of breech before described, and in some cases even for that system, he dispenses with the tail. The flange being compressed between the fixed and movable breech assists in rendering the breech gas-tight. The method of rifling consists in forming the grooves in such manner that the projectile shall be upheld truly and continuously during its passage through the barrel. The improved back sight is formed by imparting an additional and independent vertical motion to the ordinary notch, and by adding thereto two points capable of lateral adjustment to and from each other. *Patent completed.*

790. W. PHELPS. *An improved woven fabric, and improvements in machinery for manufacturing the same.* Dated March 21, 1862.

This improved fabric very closely resembles crotchet work, and is produced upon the bobbin net or twist lace machine altered to adapt it to produce the fabric. The improvements in the machine consist in adapting to it two stump bars instead of one, and in arranging the parts in such manner that, while one stands still, the other is made to move two or three gates for two motions, then that which was stationary comes into action, the other stands still, and so on. The pattern on the fabric is produced by the Jacquard in the ordinary manner. *Patent abandoned.*

791. J. WARBRICK and W. WARBRICK. *Improvements in engines for carding cotton and other fibrous materials.* Dated March 21, 1862.

This relates to an arrangement of mechanism for stripping the fibrous material from the doffers of carding engines, and consists in the use of a shaft placed parallel to, and in front of the doffer, as supported in bearings, by which it can be adjusted; this shaft carries arms, adjustable in length, to which the doffer comb is attached. Rapid oscillating motion is given to this shaft by a friction wheel (placed upon the axis of the main card cylinder) working in close contact with a small friction pulley carried upon a stud fixed in a bracket secured to the framing, and in this small friction pulley a crank pin is fixed, which is connected by a rod with an adjustable pin carried by an arm on the end of the shaft pulley in front of the doffer. *Patent abandoned.*

792. W. CLARK. *Improvements in sewing machines, which improvements are partly applicable to other machinery for giving a rotating motion always in the same direction.* (A communication.) Dated March 21, 1862.

This invention is not described apart from the drawings. *Patent abandoned,*

793. D. ABERCROMBIE. *Improvements in power-looms.* Dated March 22, 1862.

The patentee claims actuating the treadles or shedding levers of a power-loom by cams or tappets driven by a clutch, which can be kept out of gear during one or more picks, and so cause a shed to be kept unchanged during two or more picks, as described. *Patent completed.*

794. J. MARSH. *An improvement or improvements in harness for horses and other draught animals.* Dated March 22, 1862.

This consists in making the draught plates of harness movable along a grooved bar or axis on the said harness, so as to permit the pressure of the draught plate to be more accurately adjusted to the shoulder of the horse or other animal than it is in draught plates of the usual construction. *Patent completed.*

795. T. FONTENAY. *Improvements in smoke-consuming furnaces.* Dated March 22, 1862.

In the improved furnace the smoke evolved by the fresh fuel with which the furnace is fed, while receiving a proper supply of air, is caused to meet or mix (by preference as much as possible at a right angle) with the bright flame arising from that part of the fuel already in a highly incandescent state, and not emitting any visible smoke, by which the undecomposed particles of carbon contained in the smoke arising from the fresh fuel will, while being mixed with the necessary quantity of atmospheric air, be brought to the degree of heat required for combining with the oxygen of this air, and thus be transformed into the gaseous state as carbonic acid or oxide of carbon. *Patent completed.*

796. E. OWEN. *Certain improvements in the hydraulic engines known as turbines.* Dated March 22, 1862.

This consists in applying a perforated annular shield between the centre aperture and the buckets through which the water passes. The perforations are so made that, when the shield is in one position, the greatest quantity of water can pass to the buckets; when lowered or raised a short distance, a fresh set of perforations is brought into position for admitting only a part of the water, and when the position of the shield is again altered, another set of perforations is brought into position to shut off still more of the water. Any number of sets of perforations can be used, according to the variations in the power required to be exerted by the turbine. *Patent abandoned.*

797. E. LORD. *Improvements in certain machines for preparing cotton and other fibrous substances.* Dated March 22, 1862.

This is applicable to slubbing frames, roving frames, and other machines of a similar nature, and it consists, 1st, in an improved mode of arranging and constructing the differential motion, whereby less friction is produced, and, consequently, less power is required for driving the machine; 2nd, in the application of machinery for unwinding so much of the slubbing or roving off the full bobbins as will suffice for lashing or winding on to the empty bobbins or spools at the commencement of a fresh set. The object of the last part is to facilitate the operation of regulating the winding on according to the tension of the slubbing or roving. The invention is not described apart from the drawings. *Patent completed.*

798. J. DAVIS. *Improvements in wind musical instruments.* Dated March 22, 1862.

This relates to cornets and other wind instruments, and consists, 1st, in a mode of working the valve. The shaft or plug which works the valve passes into a tube projecting from the face plate, which shaft has a part cut away, so that its end may enter a slot in a short plug projecting from the valve. The shaft is provided with a shoulder, and there is a cap over its outer end to keep it steady. To the bottom of the piston rod is jointed a pin, which passes through a hole in the shaft, and acts as a lever for working the shaft and valve. By these arrangements the patentee obtains a steady working of the centre, and perpendicular action of the piston rod perfectly free from oscillation. 2nd, he constructs a chamber on the face plate, within which chamber the aforesaid chamber is made to work, the whole action being enclosed by a cap. In one arrangement he conveys the wind from the lower chamber of one valve through the upper chamber of the next, or *vice versa*. These chambers are immediately attached to each other, but not at equal distances apart, nor yet in the same line, for the purpose of bringing the finger plates central with the spring boxes, and at equal and convenient distances apart; or he obtains the same advantage by causing the chambers containing the valves to be placed in an oblique direction, and having the wind passages arranged accordingly. To regulate the position of the valve so that the apertures may be opposite the wind passages in action, he employs a circular plate, having upon it another plate partly circular, or with a portion cut away, and causes the plate to be held in the chamber. At the end of the valve there is a pin or projection, which comes in contact with the edges of the plate, and prevents the valve from being turned too far. *Patent completed.*

799. R. GLADSTONE. *Certain improvements in tilting or tipping waggons.* Dated March 22, 1862.

The first part of this relates to a form of axle by which the body of a waggon, either with or without springs, can be evenly balanced, and complete end tilting or tippling effected, and consists in bending or cranking the said axle immediately after it leaves the naves of the wheels a sufficient length horizontally or angularly towards a vertical line drawn transversely through the centre of the waggon, so that when the waggon is completely tilted or tipped endwise, it will not come in contact with the longest part of the said axle which was parallel to a line continued from one end bearing part to the other. The second part is only applicable to four-wheeled waggons with fore carriage, and consists in forming the connecting rod, which is secured to, or made part of, the axle of the hind wheel by bending it upwards and forwards, so that it will pass over the fore carriage or carriage part and couple to the main pin or "perch bolt" of the same, thus allowing the said fore carriage to turn on a small surface. *Patent completed.*

800. F. W. COLLS. *Improvements in consuming smoke, and in the apparatus connected therewith.* Dated March 22, 1862.

This consists in passing steam through pipes into the interior of the furnace, so that the steam may be superheated and decomposed into its original inflammable gases, which are discharged near the bridge of the furnace, and by uniting with the smoke cause its perfect combustion. *Patent abandoned.*

801. J. H. TUCK. *Improvements in the manufacture of flexible valves.* Dated March 22, 1862.

Here it is preferred that the valves should be made of vulcanized india-rubber. In constructing a circular or other form of valve, where the same is held by a spindle passing through it, a ring of metal or of other strong material is introduced into the interior or substance of the valve around and concentric with the hole through which the spindle passes. The object of such rings is to give additional strength to the central parts of the valve, and that the play or movement of the valves may be for the most part external of such strengthening rings. In some cases, near the outer circumference of the valve, and at a distance from the ring above-mentioned, another ring of metal, or of other suitably strong material, is introduced into the substance of the valve, which ring may, when desired, be itself flexible by being formed of links or parts connected together, if of metal or other hard material. *Patent completed.*

802. J. G. Jennings. *Improvements in the manufacture of biscuits.* Dated March 22, 1862.

Here the biscuits are made hollow, and baked so as to remain so, which can be done by filling with a piece of metal or glass, &c., which can be removed after the baking. These biscuits can at any time be filled with mince, jam, meat, &c., and thus become sandwiches. *Patent completed.*

803. T. M. Smith. *Improvements in the manufacture of candles.* Dated March 22, 1862.

This consists in combining Japan or vegetable wax with paraffin, which being melted together, either with or without other candle-making materials, make a valuable, yet a comparatively inexpensive, candle stuff. *Patent abandoned.*

804. T. F. Hale. *Improvements in valves.* Dated March 22, 1862.

This invention consists of a flat plug, corrugated or formed with annular grooves, and of a flat surface or seat surrounding the aperture to be opened or closed. The plug is forced down upon the seat to close the aperture, and is raised therefrom to open it by screw or lever. Instead of the face of the plug being grooved, the inventor sometimes makes it with an even surface and grooves or corrugates the seat. *Patent abandoned.*

805. W. Holiday. *Improvements in the manufacture of press plates.* Dated March 22, 1862.

Upon a plate of wrought-iron of about the size of the intended plate, the patentee places a quadrangular frame of about the same size of wrought metal, and within this frame he applies transverse bars of thickness similar to that of the quadrangular frame. Each of these bars is at one end fitted into a recess formed in the side of the quadrangular frame, whilst their opposite ends extend to within a short distance of the opposite side of the frame. The points of connection of these bars with the side of the frame alternate so as to leave a continuous but circuitous course from one angle to the opposite. Upon this frame and the intersecting bars he then applies another plate, and subjects the whole to a welding heat, and then to mechanical pressure sufficient to produce a welding of the surfaces in contact, yet so as to leave the channel referred to clear. He then finishes the surfaces of such plates as may be required, and applies suitable nozzles to the opposite extremities of the channel therein for the conduct, thereto and from, of heating or cooling media. *Patent completed.*

806. G. Hartshorne, jun., D. G. Ward, and W. Woolley. *Improvements in punching or perforating metal plates or sheets, and in apparatus or machinery to be employed for that purpose.* Dated March 22, 1862.

Here the patentees make two plates, termed he and she plates. The he plate is furnished with a number of pegs or projections extending up from its surface. The she plate is made with a corresponding number of holes or sinkings. The plate or sheet of metal to be pierced is then placed between these plates, and all are enclosed between two plain plates, one on the top and one underneath. The whole of these plates are then passed between rolls, and by the pressure of the rolls the pegs or projecting parts pierce the plates, and thus plates with a vast number of perforations are rapidly and economically produced. *Patent completed.*

807. M. Henry. *Improvements in kilns, ovens, and furnaces.* (A communication.) Dated March 22, 1862.

This relates to kilns, ovens, and furnaces for calcining lime, plaster, and bones, revivifying animal charcoal, burning bricks, baking or firing pottery, porcelain, and retorts, and performing other operations. In one arrangement, the kiln or oven is constructed with a sole or floor, through which numerous openings called inlet-holes are formed; furnaces or fire-places are placed directly under this sole, or nearly so, and from them the flames and hot gases or products of combustion rise through the openings in the sole into the kiln, oven, or chamber, and act on the materials or articles therein. Other openings called outlet holes may sometimes be formed through the sole, for the escape of the gaseous products from the kiln, oven, or apparatus to the chimney or elsewhere, and in this case the rows of inlet-holes should cross the row or rows of outlet valves, which may be arranged across or near the middle of the sole, the object being that the products of combustion, when acting on the matters, may be in the form of films or sheets of heat or flame. It is preferred that the whole surface of the sole should be provided with openings or holes, and that the inlet-holes should be of small sectional area, as heat is more equally diffused when entering through narrow openings than through broad flues. Blocks of brick or other ordinary contrivances may be used for reducing the sectional area of the passage through the holes to any required extent, by which the inlet-holes furthest from the fire may be opened widest, and the area of passage through the outlet-holes may be regulated according to their vicinity to the main exit flue. Doors or panels mounted on wheels or rollers, which travel on rails, may be used for opening and closing the kiln or oven to admit and remove the charges. *Patent completed.*

808. J. H. Brierley. *An improved clasp or fastener for reversible belts, bands, or straps.* Dated March 24, 1862.

Here the patentee uses one plate of metal, or other material, of any design suitable for a belt clasp, to the centre of which he attaches a bar of suitable width. He further attaches two hooks, or a double hook, or other kind of fastening, in such a position as enables him, by a catch formed out of metal, and attached to one end of the belt, band, or strap, and the clasp before described to the other end, to connect the ends of the belt, &c., either on the right or left of the clasp, so that, by connecting the belt, &c., on the right of the clasp, one side of the belt, &c., is seen, and by connecting it on the left, the reverse side of the belt, &c., is seen, and thus produces a reversible belt, &c. *Patent completed.*

809. J. Clarke. *An improvement or improvements in carriage axles.* Dated March 24, 1862.

This relates to carriage axles of the kind known in commerce as collinge axles, and consists in an arrangement for fixing upon the end of the arm of the axle, the collet or washer against which the end of the axle box works. *Patent abandoned.*

810. T. White. *Improvements in the manufacture and ornamentation of nut-crackers, and lobster-crackers.* Dated March 24, 1862.

This consists, 1st, in constructing the joints of nut-crackers and lobster-crackers in manner hereinafter described. Instead of connecting the two parts of the joint with the middle pieces by pins or axes riveted at their ends, the patentee uses pins or axes of iron, or German silver, or other metal or alloy, which are passed through the parts to be joined, and are left unriveted. The pins or axles are kept in their places by small ornamental caps fixed over them, the said caps being secured by soldering or otherwise, in depressions made in the sides of the cracker to receive them. He makes the handles of a cylindrical or prismatic figure, and fixes thereon tubes of metal, ivory, bone, &c. *Patent completed.*

811. S. E. Turner. *An improved apparatus for burning a mixture of inflammable gas and air.* Dated March 24, 1862.

This consists in introducing one or more metal tubes into the cylinder in which the jet is placed, wherein the mixture of the gas and air takes place, which tube or tubes is, or are open at bottom, and pass up through a gauge or perforated diaphragm, and into the chamber in which the combustion takes place, where it is or they are finely perforated, and is or are by preference closed at the top; or a tube or tubes of wire gauges may be used instead of the perforated portion of such tube or tubes. *Patent abandoned.*

812. C. M. Roullier. *Improvements in flat cables or chains.* Dated March 24, 1862.

This invention consists in constructing flat cables or chains as hereafter explained. The inventor takes links of hard wood, and strings them upon metal spindles. The links are formed with grooves on the face, in which wire is wound to strengthen the wood, and with metal plates on the sides, which plates may be alternately zinc and copper, and which, when the cable is complete, should be in contact with each other. The metal spindles may be covered with caoutchouc or gutta percha to impart suppleness and elasticity to the joints, and to prevent the effects of wet and damp. The links also should be coated with caoutchouc or gutta percha. Two spindles pass through every link, one near one end and the other near the opposite end of the link. *Patent abandoned.*

813. B. Fleet. *Improvements in apparatus for manufacturing and bottling soda water.* Dated March 24, 1862.

This relates, first, to combining in one machine the apparatus for making soda water, and a steam engine for driving the same, the same shaft and fly wheel answering the purpose of both, as also, to a great extent, the same framing. This is readily effected by disposing a steam cylinder on the bed plate of the machine, or other supporting part, and mounting a crank on the end of the machine shaft to which the piston rod may be directly connected, or it may be otherwise arranged. A suitable feed is also applied to supply the boiler. The second part relates to the lifting apparatus. This the patentee disposes at that part of the machine from which the soda water is ordinarily drawn and as bottled by hand, by which and other arrangements the soda water is even better than that bottled by hand, and infinitely superior to that bottled by rack-bottling machines. The channel in which he places the cork, guiding and forcing it into the bottle, he forms cylindrical, and fits therein a plunger, by which the cork is driven into the bottle. The plunger has a cap, leather or other packing, near the nose, which fits the cylindrical passage receiving the cork, and prevents the escape of gas upwards, while the bottle neck being pressed upwards against a soft substance at the lower part, as usual, prevents any escape thereat. The soda water enters the cylindrical channel below the position of the cork, and when the bottle is filled, the cork is forced down by the plunger into the bottle, thus easily and effectually bottling the soda water. The plunger is brought down by a screw of rapid pitch (an eight-thread screw), so that about one half a turn is sufficient, which forms a feature of this invention. *Patent completed.*

814. J. Topham. *Improvements in apparatus used for cleansing out the scum and removing the sediment from the water in steam boilers, and preventing incrustation therein.* Dated March 24, 1862.

We cannot here devote space to the voluminous details of this invention. *Patent completed.*

815. E. Morewood and A. Whytock. *Improvements in the process of coating metals, and in the apparatus employed.* Dated March 24, 1862.

This invention relates to the use of resin, or a mixture of resin and tallow, as a flux on the surface of melted lead or tin, or alloys of those metals, when coating iron or other metal, by using two or more coating baths, worked in connection by the aid of machinery, which causes the sheets to pass from one bath to the other whilst in the process of coating. *Patent completed.*

816. W. Hensow. *Improvements in knitting machinery.* Dated March 24, 1862.

This consists in so arranging such machinery that the number of needles in the circle or ring may from time to time be increased or decreased by causing needles to be introduced into or withdrawn from the circle or ring, the circle or ring carrying the needles being at the same time proportionately increased or decreased, so that the needles which are for the time being at work may be equally spaced. *Patent abandoned.*

817. J. Stewart. *Improvements in the manufacture of cards for jacquard weaving.* (A communication.) Dated March 24, 1862.

This relates to a system of removing the cards used in jacquard weaving mechanism, so as to avoid waste of material. Under one modification an old card is taken, and the layers of paper which form the card are stripped asunder, and to each layer or half of one card is glued or otherwise cemented a new strip or length of card paper. The remaining half of the card is in like manner glued or cemented to another strip of card paper, so the parts again form two perfect cards, and when joined in this manner to the new card paper are again ready for being punched. The cards thus prepared are subsequently submitted to pressure in any convenient way, so as to cause the layers of cardboard to adhere firmly together, so forming two new cards. *Patent completed.*

818. M. A. F. Mennons. *Certain improvements in machinery for the production of ornamental stitching or embroidery.* (A communication.) Dated March 22, 1862.

This invention is not described apart from the drawings. *Patent completed.*

819. E. Molyneux, Jun. *Improvements in air, gas, and vapour engines.* Dated March 25, 1862.

This consists in a method of alternately heating and cooling air, gas, or vapour confined in an air-tight vessel or vessels, and using the resulting difference of elastic force due to this difference of temperature to produce motive power. *Patent abandoned.*

820. A. H. Renton and E. Cottam. *Improvements in apparatus for steering ships.* Dated March 25, 1862.

This relates to apparatus for moving the rudder or rudders of ships, and consists in applying the power to a tiller or other lever which is usually attached to the rudder head by a hydraulic cylinder and piston of a particular construction, and also in actuating the same by pumps or cylinders and pistons driven or worked by steam or other agent, as convenience and circumstances may suggest. *Patent abandoned.*

821. W. Beaumont and J. W. Edge. *Improvements in sights for rifles.* Dated March 25, 1862.

This consists of a back sight for rifles, and relates to that description of sight in which the elevating bar has been hitherto raised by a screw working through a bearing in the back part of the elevating bar. These improvements consist in using two screws, one on each side of the back of the framework, and in fixing on the tops of the screws small toothed wheels, which turn simultaneously by one or more additional or intermediate wheels. The elevating bar, which is tapped to receive the two screws, is raised or lowered by turning one of these small wheels either to the right or left. The number of teeth on the wheels which are connected to the screws for raising or lowering the elevating bar are so arranged, in proportion to the pitch of the screws, that one revolution shall be equal to one degree or half a degree, as required, of elevation. The screws which raise or lower the elevating bar may be made of double or treble threads, if found necessary, so as to give a quicker movement to the elevating box. The plate of the sliding or elevating bar containing the V-grooved or other formed sight, is so constructed that, by simply unscrewing two small screws at its base, it may be removed from its framework in order that the marksman may alter his sighting by exchanging the plate for one with a different shaped notch or V-piece, or a larger or smaller aperture through which to take the sight, according to the weather or other circumstances, as is well understood. *Patent completed.*

822. A. Fryer. *Improvements in the manufacture of sugar, and in separating liquids from sugar and other substances.* Dated March 25, 1862.

This invention consists, first, in a method of crystalizing the sugar held in syrups. The inventor stores the syrups when boiled in what he terms a crystallizing vessel of large capacity and great depth. He prefers that the vessel shall not hold less than 50 tons, nor be of less depth than 30 feet, the larger and deeper the better. The crystalizing vessel is kept nearly full, and the saccharine matter drawn off from the lower end, and is, for convenience of after treatment, led thence by a pipe into a small discharging tank, fixed nearly as high as the top of the crystallizing vessel. By this method the boiled syrup cools slowly, and the lower portions being removed, as fresh boiled syrup is added at the top, each portion of material, in its downward course, is subjected to gradually increasing, and eventually to considerable pressure, which, together with slow cooling and length of time, produces a more than ordinary copious crystalization. As it is better not to allow the temperature of the sugar to fall below 105 Fahr., he surrounds the vessel, if needful, and especially if such be of small diameter as the minimum aforesaid, with a casing, or employs other means to maintain the temperature. The second part of the invention consists in a new method of and arrangement of apparatus for separating sugar from syrup, and for the removal of liquids from solids generally. In explaining this part of the invention the patentee supposes he is operating on saccharine matter that has passed through the crystalizing vessel to the discharging tank before referred to. The separation of the sugar from the syrup is thus effected:—He folds portions of the saccharine matter in cloths or other porous material forming parcels, and he places these parcels one upon another until they form a pile or column from about 20 to 50 feet high or upwards. Each parcel is thus subjected to a gradually increasing pressure, commencing at first within superincumbent pressure, and eventually receiving the pressure due to the whole column. The syrup is thereby forced through the pores of the cloth, while the sugar is retained. The pile is kept constantly full; fresh parcels are added at the top, and the pressed ones are removed from the bottom. It is better that each parcel should be 24 hours under operation. Each parcel is separated from those above and below it by an open or reticulated plate to allow the syrup to escape freely; the whole column is retained in a vertical position by a strong framework. This framework is most conveniently placed under the valve of the discharge tank, and the material is then filled into the cloths direct. Beneath the pile a hydraulic lifting apparatus is fixed, by means of which, in combination with bars and beams for supporting the weight of the pile, the whole pile is lowered and the lower parcels are released from the superincumbent weight, and may thus be removed. *Patent completed.*

823. A. M. SILBER. *An improved fastening for purses, pocket-books, bags, and other articles.* (A communication.) Dated March 25, 1862.

Here to a plate or piece, hereinafter called a fixed or guide plate, attached to a part of the article to be fastened, is connected another plate or piece, hereinafter called a catch plate, capable or moving or working to and fro, moving in one direction to open the fastening, and in the opposite direction to close it. Two spiral springs are fitted at one of their ends to the fixed or guide plate, and at their opposite ends to the catch plate, being most conveniently connected to these plates by bent parts of the latter introduced into the ends of the springs. The catch plate has a beviled, bent, or otherwise formed part intended to act as a catch or staple to retain or engage a hook or equivalent contrivance, which is attached to another part of the article, and constitutes the second portion of the fastening, the combined catch plate, fixed or guide plate and springs composing the first portion thereof. The catch plate and fixed plate have openings in them for the hook or equivalent to pass. Those ends of the spring that are on the fixed plate are those nearest to the point or side towards which the catch plate is drawn where moved in order to open the fastening, and the ends on the catch plate are those furthest from such point or side, consequently the act of drawing the catch plate to open the fastening compresses the springs; and the act of releasing the catch plate, or causing or allowing it to return to position to close the fastening, causes the springs to return or extend to their previous form. When the catch plate and hook are engaged the fastening is closed. To open it the catch plate is drawn or pulled, compressing the springs, and the hook or equivalent is released. *Patent abandoned.*

824. T. GUTBAL. *Improvements in the construction of ventilators for the ventilation of mines and furnaces.* Dated March 25, 1862.

The patentee claims the arrangement of a rotatory ventilator or fan, the case of which communicated with an outlet passage increasing in sectional area as it passes away from the case, and which has a regulating sieve following the curve of the case to adjust the size of the outlet therefrom, as described. *Patent completed.*

825. E. MOREWOOD and A. WHYTOCK. *Improvements in the manufacture of shaping of iron or other material.* Dated March 25, 1862.

The patentee claims, 1st, the production of corrugations on sheets of iron or other material, by passing them widthways between, under, or against two or more pairs of fluted rollers, as described; 2. The use of a roller and bed for the same purpose, as described; 3. The causing sheets of iron or other metal connected together into a long or continuous sheet to pass widthways under or against a fluted, undulated, or corrugated roller, when working in connection with a bed, or to pass widthways between or against one or more pairs of fluted, undulated, or corrugated rollers, so as to be impressed or corrugated, as described, without tearing it. *Patent completed.*

826. W. PALMER. *Improvements in lamps.* Dated March 25, 1862.

Here a vessel is formed with two compartments, the oil being placed in the upper, from which one or more tubes proceed, according to the number of burners required, and the oil or fluid descends through the tube or tubes to the burners. From each burner of the lamp, another tube proceeds to the vessel, the other end of such tube being connected to the lower compartment of the vessel, so that the oil that overflows from the burner descends through such tube into the lower compartment of the vessel. In the lower compartment there is a plunger or piston, which, on being raised, carries up the oil, and causes it to pass through a valve in the partition which divides the upper from the lower compartment of the vessel, and thus is the oil which overflows returned to the upper compartment of the vessel. *Patent abandoned.*

827. C. CULLING. *Improvements in fire-arms.* Dated March 25, 1862.

This consists in applying a cheek-rest or cushion to that part of the stock of a fire-arm against which the cheek of the person when aiming is pressed. The rest or cushion is constantly pressed outwards by the action of a spring, and is in connection with a bolt, catch, or detent, which acts on and retains the hammer or trigger or other parts of the lock from movement, until the rest or cushion is depressed by the cheek pressing upon it, and then the motion of the rest or cushion is imparted to the bolt, catch, or detent, which moves so as to leave the lock free to act. *Patent abandoned.*

828. W. CLISSOLD. *Improvements in carding engines.* Dated March 25, 1862.

This invention is not described apart from the drawings. *Patent completed.*

829. J. T. LOFT. *Improved machinery for covering strips of metal and wire.* Dated March 25, 1862.

Here, in covering crinoline steel, the patentee prepares narrow ribbons or strips of woven or felted fabric, and encloses the steel or other metal strips in the fabric by lapping the fabric around the metal, using for the purpose special arrangements of machinery. *Patent completed.*

830. L. DE LA PEYROUSE. *Improvements in the preservation of animal substances.* Dated March 26, 1862.

According to this invention hides, skin, wool, and a variety of other animal substances, are treated according to a certain process with solutions of the compounds of chloride with magnesium, either alone or in combination with other chlorides, either of the metals or of the alkaline earths, or of the alkalies, or with other suitable salts of the metals, of the alkaline earths, or of the alkalies. *Patent completed.*

831. J. H. JOHNSON. *Improvements in apparatus for cleaning tubes and flues of steam boilers and similar conduits.* (A communication.) Dated March 26, 1862.

This consists in the use of the rush known in South America as "piagava" or "bastin," either as an entire substitute for bristles or tufts of wire, or combined with those substances. The tufts of rushes are fixed in any convenient way into a stack of wood, or into branches or stems of wire, and are then trimmed to a cylindrical or other desirable form. *Patent completed.*

832. J. WILSON. *Improvements in the apparatus for, and in the method of hot-pressing or finishing plaids, shawls, handkerchiefs, and other woven fabrics.* Dated March 26, 1862.

The object here is to obviate the evils resulting from the use of small presses, and consists in placing blocks of wood or metal across or along the platten of the press, such blocks projecting over the sides or ends, as the case may be, of the platten to an extent corresponding to the length and width of the plaids, shawls, or other goods to be operated upon. The patentee uses heated plates in the operation of pressing. *Patent completed.*

833. J. PARKER. *Improvements in steam-engines and in apparatus connected therewith.* (A communication.) Dated March 26, 1862.

This consists in the means for regulating the discharge of steam from steam cylinders, so as to avoid or reduce the back pressure, especially when working steam expansively; 2, in means for allowing the escape of the condensed water from steam pipes or other passages or chambers; 3, in means to facilitate the removal of condensed water from steam cylinders. We cannot give space to the details. *Patent completed.*

834. W. J. TAYLOR. *An improved method of colouring Portland cement for plain and ornamental plasterer's work on the walls of buildings and other erections.* Dated March 26, 1862.

This consists in the addition of colouring matter to Portland cement previous to its being used for plastering purposes. *Patent abandoned.*

835. H. NUNN. *Improvements in the construction of mangles.* Dated March 26, 1862.

The object of the first part of this invention is in improved mechanism for giving motion to the ordinary box mangle, and consists in converting and transferring the continuous rotatory motion of the main driving axis into an alternating rectilinear to-and-fro movement of the travelling weight. Another part consists in arranging apparatus for lifting the end of the box or travelling weight when it arrives at either end of its journey. Another part consists in forming the box or moving weight in compartments, so that such compartments may receive closed vessels containing water or other fluids or matters capable of being readily discharged therefrom when required. *Patent completed.*

836. R. BOBY. *Improvements in hay-making machines.* Dated March 26, 1862.

In these machines the several parts operate with equal effect in either direction. The teeth, or tines, are made straight, so that in whichever direction the rotating frame may be driven, the teeth will act properly on the hay. The reverse action of the rotating frame is obtained by double pinions, which are capable of sliding along their shaft or axle, so that they may be put in gear with the driving cogwheel affixed to the spokes of the travelling wheels of the machine when required. The shafts are adapted to a hollow front bar, which carries part of the disc adjustment, and they are therefore capable of being turned upon a central point or axis, which will admit of the travelling wheels being lifted off the ground, so that they may be removed or taken off their axles without inconvenience. The fork heads that carry the teeth project beyond the circumference of the running wheels, and therefore when the fork heads are lowered, they will form a fulcrum on which the machine will rest when the wheels are to be lifted off the ground. *Patent completed.*

837. J. BOOTHMAN. *Improvements in beehives and apparatus connected therewith.* Dated March 26, 1862.

We cannot here quote the voluminous details of this invention. *Patent abandoned.*

838. J. TAYLOR and C. H. MINCHIN. *A suspender or improved gallery for supporting the shades of gas or other lights.* Dated March 26, 1862.

Here the inventors make a fixing bending a little upwards, which fixing is screwed on the gas fitting, so that the flame of gas issuing from the said fixing will ascend as nearly as possible vertically, and thus avoid the danger of breaking the shade. To this fixing they attach an elastic spring or clip, to support the globe or shade, which will hold or support it without the aid of the ordinary thumb screws and hooks. *Patent abandoned.*

839. H. CARR. *Improvements in applying lubricating fluids to the journals of railway carriages and locomotive engines.* Dated March 26, 1862.

This consists in effecting the lubrication of the journals of railway carriages and locomotive engines, while the same are in motion, by causing a spring fixed in the lubricating chamber or grease box of the axle box (which spring receives a vibratory motion from the shaking of the carriages when in motion) to convey by contract a small quantity of the lubricating fluid to a capillary thread, which thread conducts the fluid thus imparted to it to the journal below by passing down a small tube fixed in the bottom of the lubricating chamber or "grease box," and rising above the level of the lubricating fluid. To prevent the fluid splashing about, and to preserve a regular and even surface of the same, the inventor divides up the lubricating chamber into cells, by perforated partitions, in one of which cells he fixes the aforesaid capillary thread, conducting tube, and spring, or the vibrating end of the spring. *Patent abandoned.*

840. R. GRIFFITHS. *Improvements in weapons of warfare for naval purposes.* Dated March 26, 1862.

This consists in the application to vessels of war of an apparatus which may be put in motion from the interior of the vessel by steam or other motive power, so as to force out a sliding bolt or bolts against the bottom sides, or other part of an enemy's vessel, so as to punch or pierce holes therein below the water line, or elsewhere, if desired. *Patent abandoned.*

841. W. L. WINANS. *A new or improved mode of mounting and apparatus for manœuvring ordnance in land fortifications.* Dated March 27, 1862.

This consists in mounting the gun or other piece of ordnance, together with its carriage, on a platform, which is capable of being raised and lowered by steam or other power. This platform will be mounted on an under framework, on which the platform (with the gun thereon if required) will be made to traverse on a pivot, so that the gun, &c., may be turned round in any direction. *Patent completed.*

842. A. V. NEWTON. *An improved process of and apparatus for separating the fibres of wool, flax, hemp, and other vegetable substances, and extracting the colouring matters therefrom.* (A communication.) Dated March 27, 1862.

This consists in effecting the separation of the fibres of such substances by whipping, beating, rubbing, grinding, or pricking them while they are exposed to the action of water. Also in the washing out of the colouring matters and gums, and other soluble parts from such substances, by changing the water while the said substances are being whipped, beaten, rubbed, ground, or pricked, and while they are at the same time subjected to the action of water. The separated and bleached fibre thus obtained is applicable as paper stock, or in the manufacture of textile fabrics, according to its nature. *Patent completed.*

843. J. HAWORTH. *An improved method of conveying telegraphic messages and signals by means of electricity without the intervention of any continuous artificial conductor.* Dated March 27, 1862.

This invention is not described apart from the drawings. *Patent completed.*

844. W. GREENWAY. *Improvements in the manufacture of bolts for fastening doors, and for other like purposes.* Dated March 27, 1862.

This invention is not described apart from the drawings. *Patent completed.*

845. J. D. SCHNEITER. *An improved method for printing the letters, numbers, musical, or other similar characters, of maps, plans, sheets of music paper, or other similar impressions, the said method being also applicable to the preserving of printing surfaces.* Dated May 27, 1862.

By means of transfer, or other suitable ink, and typographic, lithographic, or other printing, the inventor produces on suitable lines, on very thin sheets of metal, or other suitable leaves or thin sheets, series of alphabets, or other characters or signs made use of in printing, after which these printed leaves may be etched and gummed in the usual way in lithographic printing, and be kept in store till required for use. Any one or more of the inked letters or characters may be cut off from the leaves and serve as movable leaf metal type for composing with words or other suitable compositions, for which purpose the said leaf metal types are glued or otherwise made to adhere firmly with their back to a lithographic stone, or sheet of metal, or other suitable surface, so as to allow of impressions being taken from the said thin type at once on paper, or taking a transfer thereof on lithographic stone, sheet metal, or other suitable printing surface. Or, by pressing, casting, galvanoplastic, or other suitable means, a sort of mould may be obtained, either from the plate with which the letters or other characters were printed on to the thin metal leaf, or from the movable leaf metal types, from which mould an impression may be made on leaf metal, to be used in the manner above explained. *Patent abandoned.*

PROVISIONAL PROTECTIONS.

Dated July 12, 1862.

2012. T. Bateman, Low Moor, Bradford, card manufacturer. Improvements in the manufacture of "card cloth" used for carding wool and other fibrous substances.

Dated July 28, 1862.

2127. J. Walton, 335, Strand, Turkish bath builder, and J. Moore, 11, Upper Berkeley-street, Portman-square, veterinary surgeon. Improvements in the mode of ventilating and heating rooms, Turkish baths, hothouses, and buildings of all kinds.

Dated September 11, 1862.

2503. C. Hoyau, 4, South-street, Finsbury, watch maker. An improved portable apparatus for marking time.

Dated September 15, 1862.

2531. J. Pender, Manchester, merchant. Improvements in hoops for fastening bales, and in machinery or apparatus for making the same.

Dated September 16, 1862.

2540. G. L. Lee, Holborn Hill, lithographic artist. Manufacture of metallic shutters.

Dated September 17, 1862.

2548. S. C. Keeler, 29, Percy-street, Tottenham-court-road. Improvements in veneer-cutting machinery. (A communication.)

2554. G. Haseltine, Fleet-street, American barrister-at-law. Improvements in apparatus for the manufacture of gas from petroleum oil and water, and from cannel coals, bituminous coals, schists, tar, crude coal oil, or other hydro-carbons and water. (A communication.)

Dated September 18, 1862.

2557. P. H. Whitehead, Rawtenstall, Lancaster, manufacturer. An improved support or stand for casks, barrels, or other similar vessels.

2559. W. Todd, Heywood, spinner and manufacturer, and J. Todd, engineer. Improvements in machinery or apparatus for "collecting waste or fly" from spinning machinery, whether for cotton or any other fibrous material.

2561. G. S. Moore, Sunderland, ship builder. Improvements in ship building.

Dated September 19, 1862.

2563. T. Watts, Carisbrooke, Isle of Wight. Improvements in combined thrashing machines.

2565. W. Glass, 37, Princes-street, Stamford-street. Improvements in the treatment of sulphuret of antimony, and in obtaining products therefrom.

2566. E. de la Bastida, 43, Hart-street, Bloomsbury-square. An improved cover for chimneys, adapted to prevent them from smoking, and to facilitate the extinguishing of fires therein. (A communication.)

2569. J. Bouvet, La Rochelle, France, tinman. An improved mode of closing or sealing tin preserve boxes.

2573. W. M. Cochrane, Clattern Cottage, Kingston-on-Thames. Improvements in securing the bolts and nuts of railway fish plates.

2575. R. R. Jackson, cotton manufacturer, and J. Coupe weaving manager, Blackburn. Improvements in looms for weaving.

2577. G. Maw, Benthall Works, near Broseley, Salop, manufacturer. Improvements in the manufacture of tesseræ and other mosaic inlays.

Dated September 20, 1862.

2579. P. L. Forestier, Paris, fancy paper maker. Improvements in photographic albums.

2582. L. Dixey, 21, Kings-road, Brighton, optician, and G. Smith, Angmering, artist. A new or improved method of tinting by lithographic printing, photographic portraits and backgrounds, and embossing the same.

2583. J. Wilson, North Brixton, warehouseman. An improved composition for preventing and removing incrustations in boilers.

Dated September 22, 1862.

2585. C. Mertens, Jubilee-place, Chelsea. Improvements in machinery or apparatus for scutching and dressing flax, hemp, or other fibrous materials.

2589. W. McIntyre Cranston, 58, King William-street. Improvements in machinery for reaping and mowing corn and other crops.

Dated September 23, 1862.

2592. R. Fairnburn, Burley, near Otley, York, manager. Improvements in machines for combing wool or other fibrous substances.

2593. T. Knowles, J. Houghton, W. Knowles, and W. Houghton, Gomersal, York, machine makers. Improvements in looms for weaving.

2594. C. Pontifex, 154, Saint Paul's-road, Canonbury. Improvements in means or apparatus for removing or expressing beer from yeast or from hops.

2595. W. Dobson, Nottingham, lace dresser. A new method of producing various colours on lace or other fabrics.

2596. J. J. N. Micas, Chateau de By, commune de Thomery (Seine et Marne), France. An improved railway brake.

2597. R. A. Brooman, 166, Fleet-street, patent agent. Improvements in lighting apparatus. (A communication.)

2598. R. A. Brooman, 166, Fleet-street, patent agent. Improvements in photographic apparatus. (A communication.)

2599. S. H. Laurent, 29, Boulevart St. Martin, Paris. An improved railway brake.

Dated September 24, 1862.

2601. J. Farran, Manchester-road, Bolton-le-Moors, manager. Certain improvements in looms for weaving.

2603. W. Taylor, Chester. Improvements in blacking or polish.

2604. R. A. Brooman, 166, Fleet-street, patent agent. An improved composition for painting. (A communication.)

2605. W. Maddick, Liverpool, garancine manufacturer. An improved process or method of treating and preparing madder for dyeing purposes.

2606. D. Posener and A. Posener, Rupert-street, Haymarket. Improvements in the manufacture of india-rubber and other tobacco pouches or purses.

2607. R. R. Jackson and Æ. I. Jackson, Blackburn, Lancaster, cotton spinners and manufacturers. Improvements in the preparation and treatment of flax and other fibrous materials to be subsequently acted upon by machinery employed for preparing and spinning cotton.

2608. R. R. Jackson and Æ. I. Jackson, Blackburn, cotton spinners and manufacturers. Improvements in machinery for cutting fibrous and other materials.

2609. W. Upfill, Birmingham, iron merchant and manufacturer, and W. Asbury, engineer. Improvements in the manufacture of metallic bedsteads, part of which improvements are also applicable for ornamenting tubes and curtain and cornice poles.

2610. T. Edwards, Blackheath, gentleman. An improved mode of preparing fibrous materials for spinning.

Dated September 25, 1862.

2613. T. Kennedy, Kilmarnock, water meter manufacturer. Improvements in taps or valves.

2615. J. Raywood, Sheffield. Certain improvements in the construction of gas apparatus for the prevention of fraud, and for economizing the consumption of gas.

2616. J. R. Breach and E. B. Pyesmith, Leeds, manufacturers. An improved machine for reducing or equalizing the length of animal or vegetable fibres.

2617. J. Eardley, Woodville, Leicester. Improvements in pitch pipes or tuning pipes.

2618. W. Lea, Wolverhampton, manufacturer. Improvements in hinges for French casements.

2619. A. Potter, Birmingham. Improvements in electro-magnetic engines.

2620. P. Wright, Dudley, manufacturer. Improvements in the manufacture of parallel vices.

2621. J. R. C. Taunton, Birmingham, manufacturer. Improvements in the manufacture of metallic bedsteads, cots, and couches.

2622. E. G. Muntz, Birmingham, manufacturer. An improvement or improvements in the manufacture of axles.

2623. T. R. Harding, Leeds, hackle pin manufacturer. Improvements in machinery for opening, cleansing, and carding fibrous material.

Dated September 26, 1862.

2625. J. J. Bates, Birmingham, architect and surveyor. A new or improved window sash fastener and guard.

2626. E. Dixon, Wolverhampton, manufacturer. Improvements in machinery and furnaces used in the manufacture of welded iron tubes.

2627. C. D. Abel, 20, Southampton-buildings, Chancery-lane. A new or improved purifying or preservative lotion for the mouth. (A communication.)

2628. J. Milner, R. D. Milner, and F. Hurd, Wakefield, machinists and co-partners. Preparing fibrous substances.

2630. W. M. Cochrane, Clattern Cottage, Kingston-on-Thames. Improvements in securing the bolts and nuts of railway fish plates.

Dated September 27, 1862.

2631. F. R. Stack, Whetstone. Improvements in escalading apparatus for military purposes.

2632. J. Crosby, Shepley Hall, Audenshaw, near Manchester, flax spinner. Improvements in carding engines.

2633. H. Hutchinson, 26, Rue Notre Dame des Victoires, Paris, merchant. Improvements in machinery for covering wire with india rubber and gutta percha, and similar gums and compounds thereof, and for manufacturing tubes and other articles of such gums and compounds. (A communication.)

Dated September 29, 1862.

2635. J. C. P. Bauchard, Nouvion en Thérache, L'Aisne, France, miller and baker. A twice-transversal kneading trough.

2636. H. Baum, Elberfeld, Prussia, manufacturer. Improvements in the manufacture of moreens and such like fabrics.

2637. J. Brown, Middleton, Lancaster, machinist. Certain improvements in carding engines employed for carding cotton and other fibrous substances.

2639. M. Puddefoot, Blisset-street, Greenwich, hat manufacturer. Improvements in apparatus for tilling land.

2640. W. B. Lord, Sandgate, veterinary surgeon, Royal Artillery, and F. H. Gilburt, gentleman. Improvements in loading firearms, and in blasting.

2641. W. E. Gedge, 11, Wellington-street, Strand. An improved furnace for casting steel. (A communication.)

2643. H. Hirsch, 65, Bridge-road, Lambeth. Improvements in apparatus for showing combinations of colours.

2644. The Rev. H. Moule, Fordington Vicarage, Dorchester. Heating frames and the beds of hot houses.

2645. H. Ellis, Bangor, North Wales. Improvements in the manufacture of compounds of silica, and in the application of certain compounds of silica to mineralize woven fabrics, paper, and paper pulp, to harden and preserve stone and cement in the production of artificial stone and paint, and in the production and glazing of porcelain and such like manufactures.

2646. J. Bucknall, Boston, Lincoln, mechanic. Improvements in the construction of horse shoes.

2647. J. Addison, St. Heliers, Jersey, captain. Improvements in moorings or apparatus for securing articles, applicable also to the fixing of chairs for railways.

2648. R. A. Brooman, 166, Fleet-street, patent agent. Improvements in saddle trees and collars. (A communication.)

2649. J. H. Johnson, 47, Lincoln's-inn-fields, gentleman. Improvements in shells for war purposes. (A communication.)

2650. W. Carrick, and William Carrick, jun., Carlisle, hat manufacturers. Improvements in felting apparatus.

Dated September 30, 1862.

2652. E. J. M. Le Bréton, Neuilly-sur-Seine, near Paris, gentleman. An improved propeller for boats and ships.

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

1637. A. Gilbey. Packing cases.

1639. G. Ermen and R. Smith. Fibrous materials.

1659. C. H. Roeckner. Constructing coffer dams.

1671. W. H. Hall. Safety lamps.

1674. S. Weston. Trusses.

1676. J. Fincham. Facilitating the repairing of roads and ways.

1680. W. James. Bolts, spikes, and nails.

1681. T. Allcock. Horse rakes.

1683. G. Allibon and E. Snell. Surface condensers and superheaters.

1684. G. B. Toselli. Mixing syrups.

1688. E. Scheutz. Rototary engines.

1695. R. Robinson. Fire-escapes.

1696. J. M. Stanley and J. Stanley. Diffusing heat.

1703. W. E. Newton. Construction of organs and other wind instruments. A communication.

1710. A. J. Adams. Riding fire-arms.

1711. G. D. Hatton. Presses.

1718. J. Keeling. Manufacture of gas.

1723. A. Knowles. Washing extracted wool and other fibre.

1729. G. T. Jourdain. Treating cocoa-nut oil.

1730. H. C. Jennings. Preparation of skins.

1739. W. Crook. Looms.

1743. B. W. Gerland. Manufacture of sulphate of copper.

1745. J. Hetherington. Lubricating revolving surfaces.

1747. I. Spight. Horse shoes.

1749. A. A. Lerenard. Improved cement.

1754. M. Jackson. Improved shield.

1760. C. A. Tyler. Improved holder for holding dinner and other plates.

1766. J. Robinson. Machinery or apparatus for sawing wood.

1769. J. Sawyer. Steam boiler and other furnances.

1790. J. Nield and T. A. Nield. Moulding or manufacturing pipes.

1794. W. Clark. Manufacture of buttons.

1796. J. Kellow and H. Short. Blasting powder.

1818. J. Bedford. Irons and cutters of planes.

1834. S. Holman. Pumps and valves.

1913. T. Parker. Tinting or dyeing fabrics composed of mixed animal and vegetable fibres.

1924. E. de Labastida. Manufacturing india-rubber articles. A communication.

2051. J. Willcock. Ornamental fabric. A communication.

2255. L. Serbat. Lubricating machinery.

2367. L. Jarosson. Machinery for bleaching or washing textile fabrics and materials.

2565. W. Glass. Treatment of sulphuret of antimony.

2621. J. R. C. Taunton. Manufacture of metallic bedsteads.

2623. T. R. Harding. Machinery for opening, cleansing, and carding fibrous material.

2627. C. D. Abel. Purifying and preservative lotion. A communication.

2656. G. Haseltine. Warming and ventilating buildings. A communication.

The full titles of the patents in the above list can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list who have given notice of their intention to proceed, within twenty-one days from the date of the *Gazette* in which the notice appears, by leaving at the Commissioners' office particulars in writing of the objection to the application.

PATENT APPLIED FOR WITH COMPLETE SPECIFICATION.

Dated October 1, 1862.

2656. G. Haseltine, 100, Fleet-street. Improvements in the means for and mode of warming and ventilating buildings. (A communication.)

PATENTS ON WHICH THE STAMP DUTY OF £50 HAS BEEN PAID.

2271. G. A. Smith.
2443. W. Clark.
2331. T. Twells.
2334. W. Prosser.
2320. J. Carrick.
2343. G. Price.
2336. W. Burgess.
2316. J. Skertchly.
2338. T. Vicars, T. Vicars, T. Ashmore, and J. Smith.
2345. J. Jack.
2367. W. E. Newton.

PATENTS ON WHICH THE STAMP DUTY OF £100 HAS BEEN PAID.

2243. W. Rothera.
2317. H. Bessemer.
2319. H. Bessemer.
2321. H. Bessemer.
2325. H. Bessemer.
2327. H. Bessemer.
2309. W. Cotton.
2553. J. Wilkinson.

LIST OF SEALED PATENTS.

1048. E. Butterworth.
1052. J. Howard, T. Bousfield and T. Phillips.
1053. I. Whitesmith.
1055. N. Nussey.
1058. E. Drewett.
1062. E. Paton and W. Batho.
1063. J. F. Spencer.
1075. R. A. Brooman.
1076. R. A. Brooman.
1080. T. H. Bennett.
1081. F. A. Le Mat and C. F. Girard.
1086. J. Platt and W. Cheetham.
1087. J. Platt and W. Richardson.
1090. T. W. Gray.
1091. F. C. Philippson.
1096. T. Edwards and J. Harrison.
1097. J. Barbour.
1100. D. Stott.
1110. J. H. Johnson.
1120. W. Harling, J. M. Todd, and T. Harling.
1122. J. Murphy.
1125. J. L. Perin.
1128. R. A. Brooman.
1132. S. Rideal and R. Shepherd.
1133. W. Clark.
1134. J. C. Rivett and J. M. Hetherington.
1135. R. Wedgwood.
1138. J. S. Phillips.
1145. E. Loysel.
1148. A. N. Wornum.
1150. H. Lumley.
1168. S. S. Putnam.
1171. A. Warner.
1174. R. Boby.
1179. G. H. Birkbeck.
1192. W. Haggett.
1193. H. Wheatley.
1194. J. Bond.
1204. R. Zimara.
1230. W. Clark.
1235. G. Bischof.
1268. G. Davies.
1295. R. Walker.
1333. F. Marrel.
1506. F. E. Sickels.
1529. H. B. Barlow.
1833. J. Anderton.
1874. G. Peterson.
2007. T. Hill.
2230. G. Haseltine.

Note.—Specifications will be forwarded by post from the Great Seal Patent Office (publishing department) on receipt of the amount of price and postage. Sums exceeding 5s. must be remitted by Post Office Order, made payable at the Post Office, High Holborn, to Mr. Bennet Woodcroft, Great Seal Patent Office.

THE
MECHANICS' MAGAZINE.

LONDON, FRIDAY, OCTOBER 24, 1862.

THE MACHINE-TOOL SUBSTITUTES FOR THE FILE IN THE INTERNATIONAL EXHIBITION.

Mr. Fairbairn remarked the other day at Cambridge in the course of his address to section G of the British Association, alluding to the International Exhibition, "that he did not believe "that at any former period there had been "such an exhibition of machines and of tools, "which are the creators and makers of the "machines themselves. Some of the tools, "such as the turning, boring, planing, and "slotting machines, are of a very high order, "and the tool machinery for the manufacture "of fire-arms, shells, rockets, &c., is of such "a character as to render the whole opera- "tions, however minute, perfectly automaton "or self-acting, with an accuracy of repeti- "tion that leaves the article when finished "identical with every other article from the "same machine. Such, in fact, is the per- "fection of the tool system, as it now exists, "that in almost every case we may calculate "on a degree of exactitude that admits of no "deviation beyond a thousandth part of an "inch."

Such a comment from the Nestor of engineering would be sufficient to justify more notice than we have space for on this subject, even if it were not of the importance that it undoubtedly possesses.

The designing of machine-tools is certainly the most important branch of practical mechanics, as upon it depend the quantity, and to a great extent the quality also, of all other machines; and it is probable that every advance in this direction is followed by a proportionate extention in the use of machinery. There is no doubt that one of the principal means by which English manufacturers keep ahead of the cheap labour of the continent is by their machine-tools. An English fitter gets just about double the wages in cash that the French and Belgian "ajusteur" or the German "schosser" receive per day. How foolish and suicidal therefore is the smouldering jealousy as to the extension of machine-tools that we have often noticed amongst English operative engineers. This feeling is certainly diminishing, but it still exists to some extent, as we have witnessed. The use of machinery in most arts has the effect of requiring more intelligence in those working it than is wanted in hand labour. No doubt there is less demand for certain kinds of skill; there is less hard chipping and filing, but there is more erecting to be done. There has been a kind of complaint that there is nothing very original in this department, amongst others, of the mechanical exhibition. We have no doubt that if the Americans had fully exhibited they would have shown us several new notions in this line. It would be too long a digression to examine into all the reasons of this being a very probable case, but apart from such causes as the dear labour and cheap education in America, and also the excellent patent law of the States, there does not appear to be in the New World that horror of novelty, because it is new, as there is with us. Busy, bustling ignorance will often achieve more than quiescent science, and the history of human knowledge is a history of tentative experiments. We make these allusions because we really believe that our tool makers generally are too conservative, and too much given to copying each other. There are no doubt many things that might be tried. For instance, the the practicable application of any harder and tougher material than steel, let us say, Rhodium, giving a harder and tougher working edge to the cutting tool, would effect a great revolution in working cold iron, by allowing the tools to travel at a greater speed, and to take a heavier cut than at present. Of course we are well aware that all machine-tools are more or less substitutes for the chisel and file. For instance, even the moulding machines introduced into all large shops having a repetition of work, do away with much fitting, from the castings therefrom being much more accurate than those produced by hand. (We intend to describe these latter more in detail in a future number. There is, however, a class of tools which can more especially be called filing machines. These are, the shaping machine with a reciprocating tool, the shaping machine with revolving cutters, and lastly, the various new kinds of emery-wheels for grinding and polishing, introduced of late years, to meet new requirements. . . . Most practical mechanics visiting the Exhibition, will have observed that the details of Whitworth's machines in the western annexe are not at all touched by the file. For instance, in his shaping machines, the handles, links, ratchets, eyes of rods, &c., are merely shaped out and case-hardened. The furrows left by the tool are pretty plainly perceptible; but the surfaces look neater to our eye than those in the marine engine of Humphreys and Tennant, close by. The latter are certainly drawfiled, but the file scratches and "pin" marks are very plainly seen. Mr. Humphrys, who is said to be "pleasantly" strict with his men, seems for once to have been a little lax. This machine-tool is euphoniously styled the "jigging" machine in the Lancashire shops; we presume from its lively appearance in working to and fro. Mr. Naysmith, of Patricroft, has the name of having first brought it out, and it, no doubt, helped to "jig" him into a fortune. The French call it a "limeuse" or filing machine. Most of these machines in the Exhibition are upon the same plan, the work being stationary, while the tool is moved along in a travelling head, worked by a ratchet motion and screw, the tool and work being reciprocally moved on what might be called the method of double ordinates. Most of the larger-sized ones have a quick return motion, to gain time in the back stroke. It is a noticeable thing that in almost all Mr. Whitworth's machines with a reciprocating action, from his largest planing down to his smallest shaping machines, there is always some contrivance or other for saving time in the return movement.

A miniature shaping, or rather slotting machine, for nuts and bolt-heads, by Hartmann, of Chemnitz, in Saxony, has attracted some attention. We believe it to be patented in England. It has a double frame with two slides, each one cutting vertically the opposite faces of the same nut at the same time. The nut is fixed on a vertical spindle, with detent revolving motion. The machine is of rather slim proportions to an English eye. We believe that the price of this machine is about £90.

We remember to have seen in the extremely well-managed shops of Messrs. Clayton and Shuttleworth, of Lincoln, the eminent agricultural engineers, an excellent and original little tool of their own make. They use it principally for shaping the brass eccentric straps of the innumerable portable engines they send to all parts of the world. It consists essentially of a kind of rough file, with teeth shaped somewhat like those of a circular cutter, and worked up and down in a species of small slotting machine. The eccentric straps or other details are traversed underneath on a table. It seemed to do its work very quickly and neatly. This machine may be said to form a connecting link between the reciprocating and circular-cutter shaping machine.

It appears to be a general problem in practical mechanics to substitute in all machines, when possible, a continuous circular motion for the rectilinear reciprocating movement. The history of the steam-engine, of the steam printing press, of the iron manufacture, &c., are examples of this. The economy of time by a continuous action, and of "vis viva" in the avoidance of shocks, are the objects sought to be attained.

The lathe is the perfection of a machine-tool, both as to quality and quantity of work done. No time is lost in the return of the tool; a higher speed is allowable from there being no blow or impact, and from these reasons again, a smoother surface is obtained. It gives much cheaper work, surface for surface, and sum for sum of molecular forces overcome, as compared with reciprocating tools, although with the lathe a highly-paid operative is employed, and as compared with the circular shaping machine from its allowing a heavier cut to be taken.

The circular, or rose-cutter, is called a "fraise" in French, the same word being used by them to designate the peculiar collars or ruffs, very similar in outward appearance to this tool, worn in the reigns of Good Queen Bess and James I.; and in which the former is always pourtrayed. The advantages of the circular cutter are, amongst others, continuous action, and the cheapness of the structure required for developing the same. Its counterbalancing disadvantages are the expense and risk in manufacture—it being so subject to spring in the tempering—the difficulty in sharpening it, and its want of adaptability to varying work. The spindle on which it is fixed is also liable to vibrations if not well secured at both ends. This jarring action would be diminished if the teeth were made at an angle to the axis; but then the manufacture would be a rather more expensive job. The circular form, also, does not permit of the cutting edges being of a strong shape, so that the cut to be taken is rather limited in depth. If a larger diameter of cutter be used, most of the other difficulties increase in the same ratio.

It has sometimes occurred to us that an inexpensive and effective rose-cutter might be made in the same way as Biddell's patent cutters used in the oat mills sold by Ransomes and Sims, of Ipswich. The specification, No. 1,355, year 1855, does not specify cutting in metals. Steel cutters are fixed in a cast-iron disc by placing them in the sand and casting the metal round the inside ends. The spokes of locomotive wheels used to be fixed in this way. It is still in use for railway carriages and portable engine wheels. The spokes of the pulleys for mining hoists, and the blades of some kinds of turbines are united to the bosses on this plan, only inferior in solidity to a wrought-iron forging. The whole is then tempered in water or oil when at a red heat, and the result is a steel edge with a tough iron back. The edges might be kept sharp on a grinding machine with narrow stones, like the one of the Messrs. Robinson, in the Western Annex, with the addition to it of a slide rest. We also do not see why a broad cutter should not be built up out of several narrower ones. With all its defects this kind of shaping machine is in extensive

use, not merely for nuts and bolt-heads, but for grooving screw-tops, cutting out forked joints, and grooves generally, &c. It is more especially adapted for a repetition of work, and is therefore more useful in a locomotive shop than in one for making stationary engines. It is also very extensively used by the gun-makers. Two of the most original and ingenious machines of this class are shown by Greenwood and Batley. One, which they call the edge or profile-milling machine, to copy irregular figures, is especially useful. It consists of a bed, with a cross piece carrying a transverse slide over the movable table which supports the work. Upon the transverse slide is fitted a vertical slide which carries the spindle with its cutter. Both these slides are free to move by means of a hand-lever which passes into a universal joint. The table upon which the work is placed is also free to move longitudinally by hand motion. Upon the vertical slide, parallel with the spindle, is placed a steel tracer, of the same size as the cutter. The work to be cut is fastened upon the table, and by its side is fixed a steel copy of the form required to be produced. The machine is put in motion (the spindle being driven by a strap passing round a long wooden drum driven at back of machine and through a space on the slides), and the steel tracer is held by means of the hand-lever in contact with the copy, and at the same time the table is moved by the other hand of the operative, so as to traverse the length of the article to be cut. By the action of these slides all the intricacies of the shape of the copy are followed by the tracer, and the cutting tool shapes the work to the exact form of the copy. Sock plates, hammers, butt plates, trigger guards, and many other parts of the rifle are shaped in this machine, and it would no doubt be very useful for many jobs in any engineering shop.

The second machine of the kind at this most interesting stand is termed by the makers "the straight milling machine." In this machine the spindle is driven by a wheel and pinion, the teeth of which are cut diagonally, or more correctly speaking, the teeth of the wheel and pinion form two screws of as many threads as teeth, and working into each other. The object of this form of tooth is to prevent any back lash, and to produce smoothness of work. The table cannot be altered vertically, but the journals of the spindles are made to adjust up and down by screws. The spindle is held endways by means of hardened cast-steel collars, which are carefully ground. This machine has a self-acting table, with an apparatus to instantly stop the machine when the work is finished cutting. The cutters are made to the form required on the surface of the work, and ground up in their places on an arbor, being mounted on the driven spindle, and the end of arbor carried by a loose head which is adjusted to the same height as the main spindle. This machine, with suitable fixings, is said to perform nearly one-fourth part of all the shaping required for the rifle. A great number are being used in Birmingham.

Whitworth, of Manchester, Smith, Beacock, and Tannett, of Leeds, also exhibit in this line.

Fairbairn & Co., of Leeds, show a neat little "pentagraph cutting machine" for toothing turned-up circular cutters, by means of another small revolving cutter, moved on the pentagraph principle.

We now come to our third classification of machine-tool substitutes for the file; that of grinding and polishing machines. The grindstone has always been used in engineering shops for rough work—particularly for cotton machinery — such as taking the skin off cast and wrought iron previously to polishing it up by the "glazer." There is a limit to the speed of the stone, as it is apt to fly to pieces by the centrifugal force. We believe that the Journeymen Grinders' Society require the speed of stone not to exceed 2,800 ft. per minute. We have seen a man killed in this way. The stone broke in laminæ at right angles to the axis of spindle. The "glazer" being merely a piece of leather on a pulley, on which the emery or corundum is glued, is also not very durable. Of late years, in consequence of chilled cast-iron and case-hardened wrought-iron surfaces being more extensively used, it has been found necessary to use grinding talles to take out the irregularities of surfaces caused by these hardening processes. As remarked by Professor Rankine, in the Jurors' Reports: "With respect to material, the most striking improvements since the 1851 Great Exhibition, are those which consist in the greatly extended use of steel, and of iron approaching to steel in its properties." We remember to have seen, about two years ago, in the well-known Atlas Works, Manchester, a machine for polishing their steel or case-hardened slidebars, &c. It consisted of two stones or emery rollers, placed in lieu of the tool-boxes on an ordinary planing machine. The emery rollers were discs about 12 in. in diameter and 2 in. broad, and were formed of gun-metal rings 2 in. thick, shrunk on a roller. Oblique grooves are cut into the rings, and the whole is covered up with a small splasher to somewhat prevent the oil and emery, which are fed on the work, from flying off. These rings are said to last about three months in constant wear.

Another form of this machine in those works was a disc some three feet in diameter, revolving horizontally, and on which the work was pressed, while in the former arrangement the rollers were lowered by the tool-slide. Similar machines are in use in the Gorton foundry, near Manchester. The horizontal disc is also found very useful in taking the scale off brasswork. In a cursory way, we alluded last week to a trial in the western annex of Warne and Co's newly-patented emery wheels. One kind of these is formed from a mixture of india-rubber and emery, in which shape it has been long used in the States. Warne and Co., however, have lately employed the remarkable new material called oxydized oil, introduced by the firm of Walton and Co., of Chiswick, for consolidating the emery. This substance is intended as a cheaper, and is, no doubt, in many cases a superior, substitute to india-rubber. The travelling surface of the wheel shown in the western annexe was about 6,000 feet per minute, which is about the speed of Messrs. Hunt and Roskell's diamond-polishing wheels, in the same place.

By the courtesy of Mr. W. Adams, of the North London Railway Works, Bow, where they have been used for some time, we were enabled to see the wheels in practical operation. A row of five of them were placed on a spindle in the same manner as other grinding-wheels. The largest was about 18 inches in diameter. They revolved slower than the one in the Exhibition. We saw them used for fitting in the keys of wheels, and the cottars of connecting rods. It was stated that these jobs could be done by them four times quicker than in the usual way. The same company use them for "getting up" spanners, polishing steel slide-bars, &c. The whole operation is very clean, no oil or water being required. The great speed that it is possible to apply to these wheels gives them great power of abrasion. The discs revolve from the operatives, whose hands, therefore, cannot be drawn in. The writer of this notice nearly lost his hand in an ordinary grindstone in this way, some years ago, so that he fully appreciates this advantage. So pleased is Mr. Adams with this system that we believe he is making a machine to use wheels made up with a finer No. of emery for "drawfiling" surfaces.

There is also a machine with similar wheels for sharpening circular saws, at these works. From the ingenuity of the idea of this machine, and the want of sound sense in the way it is carried out, we should think it is French, An emery wheel is caused to just abrade the tip of the tooth. We do not see how these wheels can be made to grind up chisels, as the temper must evidently be lowered in the process.

Pursch, of Dresden, also exhibits small emery wheels, but we do not know what material he uses to consolidate the emery. Altogether we feel convinced that these emery wheels, and generally tools of this kind, have "a great future before them," as our French neighbours say. Emery, a mixed granular corundum ore, is only inferior in hardness to the diamond; can be had of any fineness, and brought to bear in this way safely and cheaply, can be put to a very great variety of uses in any well-conducted engineer's workshop.

There are some more machines of the kind we have now slightly treated on in the Exhition catalogue; to quote the words of the Jury, "we have carefully searched for, but not found them." A contemporary has been more fortunate, as we have seen some interesting criticisms on things which have given rise to the above pathetic complaint expressed with so much "naïveté" by the very learned Jurors.

H.

HYDRAULIC MACHINES AT THE INTERNATIONAL EXHIBITION.

The water-wheel in this country once played an important part, but as the stage-coach has disappeared in presence of the locomotive, so has the hydraulic prime mover yielded its ground to the stationary steam-engine. Water, however, though not frequently used for the purpose of communicating motion to the overshot, the undershot, or the breast-wheel, and through them to long lines of shafting and to machinery in connection with that shafting, is yet pressed largely into the service of the mechanic. In the hydraulic press, for example, we see a marvellous proof of the force which it may be made to exert; and the variety of purposes to which that force may be applied we need not tell our readers.

In the form of a combined steam and hydraulic apparatus, a very excellent specimen occurs in the Western Annex, and for the production of which we are glad to see a prize medal has been awarded by the jurors. This is the production of Mr. F. O. Ward, of Hertford-street, Mayfair, London, and is called a Patent Improved Hydraulic Pumping Engine. The engine is on the horizontal principle, and the four powerful pumps attached to and driven by it are also horizontally disposed. The latter are placed on the sides of an elongated hollow bed of cast iron, which serves to support the cylinder and guide blocks of the engine, and also as a cistern. The pumps are of a peculiar construction, and their arrangement admits of their being made longer than is usual in ordinary hydraulic pumps. The four pumps are coupled together in pairs, if it be not considered a Hibernianism to say so, and the plungers of each pair are attached to the opposite ends of an intervening slide. The slide is moved to and fro between horizontal guides by the end of a connecting rod whose

opposite extremity is impelled by the crank of a driving shaft transversely disposed across the oblique end of the cistern. The peculiar grouping of the parts upon and around the cistern is such, therefore, as to compress two machines within the area usually occupied by one. To this advantage of compactness of form, that of lightness is added, since the same casting which serves as a bed-plate for the engine also serves as a stiff framing for the pumps. It has been stated that the same casting forms a water cistern for the supply of the pumps, and it thus is really made to perform three important offices.

There can be no question about the economy and efficiency of the Improved Hydraulic Pumping Machine. There it rests like a giant in repose, but the strength and symmetry of whose limbs betoken his might when roused to action. In the internal fittings of this apparatus there are some peculiarities which demand attention, and which seem to us to make it perfect in its way. The pumps have their inlet and outlet valves both placed at one end, instead of having them, as is usual, placed at opposite ends of the barrel. The water, therefore, enters and leaves the pump at the same end, so that the annular waterway, necessary in the last case to be formed between the plunger and the barrel, is not in this required at all. The plunger is accordingly turned to fit the barrel, and no cavity remains to harbour air, so detrimental to the vacuum and suction power of the pump. The back-slip, or reflux of water through the valves during their fall, must palpably be less than in the ordinary contrivances of a like character, because the valves are less numerous, in the proportion of one to three. In fact, it does seem to us that in the designing of this apparatus Mr. Ward has presented a very strong claim to the admiration of the hydraulic engineer, and proved himself to understand practically the exigencies of the peculiar work for which that apparatus is designed. It is scarcely necessary to say that the Hydraulic Pumping Engine is intended for working hydraulic presses. With some slight modifications it might, nevertheless, be made available for other kinds of pumping work. Messrs. Wren and Hopkinson, of Manchester, are the manufacturers, under Mr. Ward's patent, and from them, therefore, the apparatus may be ordered and obtained.

Messrs. Peel, Williams, and Peel, of Soho Iron Works, Manchester, have earned for themselves a high reputation in the department of hydraulic machinery, and a press is exhibited by them in the Western Annex, which is worthy of notice. The cylinder in this case is 12 in. in diameter, and the press is calculated to be made to exert, with safety, a pressure equal to 340 tons. This is allowing the force of water-pressure to be equal to three tons on the square inch. Considering the power of Messrs. Peel and Co.'s press it has a very light appearance. The columns supporting the top are of wrought iron turned bright from end to end. The recesses upon which the collars of the columns rest are planed true to one surface, so as to ensure a fair and uniform bearing upon each corner of the framework—a point of much consequence, as an unequal distribution of the force exerted might be fatal to the apparatus. It is also furnished with extra waterways, which expedite the running down of the table. Presses of this kind are used for expressing the syrup or juice from beet-root in the sugar manufactories of Southern Russia; but of course there is an infinity of other purposes to which they may be applied.

A set of hydraulic press pumps are also exhibited by the same firm. These are worked by two independent steam-engines on the new condensing and direct acting principles. There are eight pumps in this case, four being 1¼ in. in diameter, and four 1 in. only, the length of stroke in each case, however, being 3 in.

Usually one of each size is employed for each press, and the arrangement is such, that when a pressure of one ton to the square inch has been reached, a self-acting apparatus causes the larger pump to cease its action, and the maximum pressure is arrived at by the use of the small pump alone. The pumps receive motion from eccentrics fixed upon the crank shaft common to both engines. Suitable safety valves, as well as stop and let-off valves are attached to this set of pumps. The cylinders of the steam-engine are 8 inches in diameter, and the length of the stroke is 16 inches. The speed may be varied from 80 to 100 revolutions per minute.

The whole of the arrangement is a model of compactness, and unusual facilities are afforded for taking apart every portion of the contrivance for repairs or for cleansing purposes. All the joints are metallic, and the minor details have evidently been contrived with a view to obviating the evils which practice has shown to arise in the employment of hydraulic apparatus for similar purposes.

It has been stated that the Exhibition furnishes no specimens of the water-wheels of either of the kinds so well known a few years back. There are, however, to be found therein some very good examples of the substitute for those contrivances, known as the turbine, and though we are not enthusiastic admirers of such motors, it would be improper to pass them by without notice. The most remarkable of these is shown in the form of a model by Williamson Brothers, of the Canal Iron Works, Kendal, Westmoreland. This is in reality a modification of the vortex-wheel, of which Professor Thompson, of Belfast, was the originator, and about which, some years since, a considerable amount of controversy took place. It is so constructed as to receive water at the circumference, and to deliver it at the centre. Principally this form of turbine is used for high falls, and experiments have shown it to possess, relatively with other apparatus of a like kind, several advantages. It may not be improper to allow Professor Thompson himself to speak as to the merits of the vortex-wheel or turbine. No doubt that gentleman, with the natural feelings of an inventor, has advanced as much in its favour as it is possible for any one conscientiously to do, and it will be for others to examine and estimate the value of his evidence. Professor Thompson says, that "there is in these water-wheels a very "remarkable adaptation, according to which "by the balancing of the contrary fluid pres-"sures, due to half the head of water, and "the centrifugal force in the wheel, only one "half of the work due to the fall is spent in "communicating *vis viva* to the water, to be "afterwards taken from it during its passage "through the wheel; the remainder of the "work being communicated through the fluid "pressure to the wheel, without any im-"mediate generation of the *vis viva*." It might be wished that the professor had expressed his meaning here a little more clearly, which by the judicious employment of fewer words he might, we think, have done; but the context makes that meaning more apparent. "By "this important arrangement the velocity of "the water when it moves fastest in the "wheel is very much reduced, and the loss "due to the retarding action of channels, or "passages, which cannot be entirely removed in "any hydraulic machine, is thus diminished to "a great degree. In this characteristic the vortex-"wheels have a superiority over the best "turbines of Fourneyron or Poncelet."

The well-known firm of Donkin and Co., of Grange-road, Bermondsey, exhibit also a turbine which has some peculiarities. It is intended for the reception of a vertical current, and for a very high fall. The advantages which Donkin and Co. claim for this hydraulic machine, are, that a high speed may be directly obtained from it, and economy in wheels, drums, and other gearing thus be ensured; that it is free, when in action, from the inconvenience which is so much felt in time of floods from the use of the ordinary water-wheel, and that under all circumstances its useful effects are greater than can be obtained from the last-named appliance.

The celebrated hydraulic and general engineers, Messrs. Easton and Amos, are well represented at South Kensington as regards the first-named branch of their business, and their turbine, which is on the Fourneyron principle, is adapted for either high or low falls of water. It is claimed for this that it is compact, that its working parts are easily accessible, and that its regulating gate for controlling the quantity of water admitted to it is of a superior kind.

The same firm exhibit also a Patent Combined Appold's Centrifugal Pump and Steam Engine, for drainage of marsh lands, irrigation, &c. This machine is of 40 horse-power nominal, and is driven by a pair of expansive condensing engines. The arrangement of the whole is admirable, but too well known to need at our hands a lengthened description. The pump is capable of lifting 100 tons of water per minute, at a mean lift of six feet. Smaller pumps are shown by the firm in question, on the Appold plan, as are some "Improved Hydraulic Rams" for supplying small towns, mansions, &c., with water, in sites where a small fall exists. As has been observed, the firm of Easton and Amos are well known for their practical skill in the carrying out of hydraulic works generally, and it is probable that few engineers in this kingdom, or indeed in any other, have had so much experience with regard to water-works generally as they have.

Messrs. Fontaine and Brault, of Paris, exhibit a turbine which has its own peculiar characteristics, and is a fair exemplification of French hydraulic machinery. The turbine is indeed largely used in France, and has obtained more favour in all respects among the engineers of that country, than on this side the channel; this, of course, is partly due to circumstances. The steam-engine has not found its way into many of the remote districts of the empire, and the primitive modes of impelling machinery are still therefore resorted to. We have seen some excellent specimens of water-wheels in some parts of France, and those not far from the gay metropolis itself.

One of the French turbines exhibited has, we perceive, been purchased for use at Portsmouth Dockyard.

The Messrs. Lawrence, City Iron Works, Pitfield Street, London, N., exhibit in the South-West Court a series of working models, which to the hydraulic engineer are of considerable interest. The principal of these is illustrative of their patent sluice, in which the pressure of the water is made to lift the sluice. In practice this has been found an eminently successful arrangement, and it may be seen in full operation at the Lavender entrance of the Commercial Docks, Rotherhithe. A diving-bell, with signal apparatus and safety valve for the prevention of accidents, identical with that used by Messrs. H. Lee and Son, in the construction of the Admiralty Pier at Dover, is shown in the form of a model. Other speci-

mens of hydraulic apparatus manufactured by this firm are also to be found in the court named.

We have before had occasion to refer to the hydraulic lift (Clark's Patent) as erected and in successful operation at the Thames Graving Docks, Victoria Docks, but those who desire to see an exact model of the "lift" and its accessories will find it in the South-West Court. In the South Court may be seen models of the iron floating docks of the Messrs. Rennie, to which reference has heretofore been made in these pages. The action of these admirable contrivances depends much on hydraulic apparatus, and we have deemed it prudent, therefore, in our review of the hydraulic appliances of the Exhibition, not to omit mentioning again these extraordinary specimens of engineering skill. The pumps of the Messrs. Gwynne are unquestionably worthy of observation, but those to whom the wondrous capabilities of their contrivances are not sufficiently known must be referred to former numbers of the Mechanics' Magazine.

Messrs Benjamin Fowler and Co., of Whitefriars-street, Fleet-street, exhibit hydraulic rams, force pumps, and fire-engines, all of which show distinctive marks of excellence, and prove that for hydraulic machinery of these kinds, that firm is not far behind, if behind at all, any rivals. Of the Messrs Warner, Lambert, and some other London firms, well known in the hydraulic branches of engineering, we have before had occasion to speak, and that in commendation; we, therefore, pass on to the "exhibits" of Messrs. Tangye Brothers and Price, of Birmingham, and for whom Mr. Holman, of 18, Cannon-street, E.C., is the London agent, and the hydraulic cotton and wool presses of this firm are admirably adapted for their purpose; while the Patent Hydraulic Lifting Jack is at once a novel and very practical adaptation of hydraulic agency to "common things." The Lifting Jack is portable and not at all liable to derangement. Hence, it is invaluable to the mechanic and engineer.

So far as it has been possible in a single article to deal with the question of Hydraulic Engineering as seen in the Exhibition of 1862, we have dealt with it. We are certain, nevertheless, that many points of great interest in that branch of mechanical science have been omitted. The innumerable purposes to which hydraulic power has been applied since Bramah gave us the press, would render it necessary that a volume, rather than a mere paper, should be written on the subject, if justice were to be done to it. Our cursory remarks cannot be deemed exhaustive, nor much more than introductory. If we have succeeded in indicating the main features of the hydraulic display at the vast show-rooms at South Kensington, and rendered a fair tribute of praise to those who have earned it, we shall, for the present, rest satisfied.

We are of those who believe that greater—far greater—triumphs than have as yet been achieved are in store for hydraulic engineers, and we advise young mechanics especially to devote time and attention to the laws which govern the action of fluids. Water and air have heretofore been faithful ministers to man's wants. There are, however, secrets in connection with both which time, patience, and industrious research alone can reveal.

IRON WALLS AND NAVAL GUNS.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

Sir,—In my last letter there are some errors of the press, for the correction of which I refer to the note at foot. In that letter I incidentally remark, "the main question now is, the improvement of Naval Armour." Up to this moment no progress has been made in that direction. A series of valuable experiments have been carried on by the Iron Plate Committee, but these have afforded no results of a positive character, beyond certain indications of the properties of iron requisite for armour plates. On this point even no decisive conclusions have been formed. After two years experimenting, the most that can be said, so far as the public are informed, is that the Thames Iron Works, Messrs. Beal and Co., and Messrs. J. Brown and Co., have taken the lead in the production of plates of enormous dimensions, and by successive modifications in the modes of manufacture, have greatly improved the quality and increased the thickness of the plates. Further improvements of this kind are in progress. Messrs. J. Brown & Co., at their Colossal "Atlas" Works, at Sheffield, are setting up new machinery with vastly increased power, capable of rolling still thicker plates. That enterprizing firm in its turn will be encountered by new works, on a scale of greater magnitude, which are rapidly advancing to completion at Millwall. The Butterly Iron Company, and Messrs. Rigby and Co., of Parkgate Works, Glasgow, are also in the field with great promise of success. The former firm has given a sample of its capabilities in the monster plate exhibited in the court of the eastern annexe. The manufacture of 4½-inch plates, such as those on the "Warrior," was regarded as a wonderful feat. When it was proposed to increase the thickness to 5½ and 6 inches, grave doubts were expressed whether they could be produced without deterioration of quality. It was thought the molecules of the metal could not be sufficiently compressed. But excellent plates of those dimensions have been made, and such are the extraordinary strides of mechanical skill in this country, when brought into action, that power has been devised at the "Atlas" and "Millwall" works, which it is said will turn out rolled plates of the best quality, 8, 9, and 10 inches in thickness. It is a most important point whether rolled or hammered plates have the precedence. If the reports of the Iron Plate Committee were open to public inspection we might form an opinion, but official wisdom has determined that the records of the experiments which John Bull has paid for shall not be exhibited to his eyes or submitted to his judgment. They are printed and ready for circulation, forming a goodly collection of bulky blue books, from which the ingenious mechanic and the patient engineer might, by research and analogy, evoke much that would be useful to the nation. By the publication of these records practical results would be known, controversy would ensue, new light would be thrown on many points, and the public would get something for their money. It is understood that the Committee are most desirous their reports should be published, but certain officials whose blunders would be exposed by some of the results of target trials, have influence enough in high quarters to overrule the sensible and honest recommendations of the Committee, to defeat the rights of the public, and to consign the reports, which form a formidable item in the stationer's bill, to dust and oblivion. When will the reign of unreason cease? The taxpayers are mulcted for experiments for which their representatives vote a handsome sum, and when the money is spent and results are obtained, they are refused a sight even of what they have paid for.

This much, however, has been made known. The Iron Plate Committee have come to the conclusion that the prime condition of perfection in naval armour is immensity of size of the plates which receive the impact of projectiles. For floating structures, thickness has its limit, of which, according to present notions, 6 or 7 inches is the maximum, although for the armour of land forts 10, 12, or 15 inches of solid iron are not thought too much. But in length and width for ships or shore batteries there seems to be no limitation proposed. Plates 15 to 20 feet, by 3 to 4 feet, are actually proposed for some of the iron-cased ships now in the course of construction.

It is said to be the settled opinion of the special Committee that the principle of resistance to heavy shot is the concentration in each individual plate of the strength of a massive girder, opposing its thickness, weight, and rigidity to the smashing and crushing, as well as to the penetrating effects. At first sight there seems to be much reason in this opinion, which is supported by the fact that the longer and wider the plates the fewer the number of joints. In many trials at Shoeburyness and Portsmouth the joints appeared to be the weak points.

I venture to differ with the Committee. I may be wrong, but I will state my view and give reasons for it, hoping that the frank expression of one and the other will provoke discussion, and induce some of your correspondents who are more capable than I am to deal with engineering questions to publish their opinions in the Mechanics' Magazine.

It is, I think, a mistake to constitute the armour plate a girder to resist the crushing effect. The proper duty of the armour plate is, I contend, simply and solely to resist the penetrating effect and break up the shot. In former letters I advanced that opinion and *theoretically* drew a distinction between the crushing and penetrating effects. I did so then with some hesitation, but now I can appeal to practice, and maintain the same view with more confidence. In the recent experiments at Shoeburyness with powerful guns the *local* character of the damaging effects of the 120, 150, and 280-pounder round and elongated shot was manifest. The heavy projectiles pierced the armour plates at the points, struck and fractured the structure behind. But the damage done was in the immediate vicinity of the point of impact; the more distant parts of the plate and structure were uninjured. The girder principle was not brought into action, and did not at all tend to augment the resisting force of the plate at the point of impact. The sudden blow of a projectile, with a force equal to some thousands of tons, on a surface 6 to 10 in. in diameter, cannot be compared to the passage of a train over a railway bridge. It is another order of ideas, and requires another system of resistance. The blow is local; the resistance must be local, that is, there must be equal and sufficient resistance at every point. When the armour plate alone is relied upon, we are led to enquire in what conditions it is placed. On the "Warrior" section we find a 4½-inch plate on an 18-inch wood backing. The wood offers no resistance worth speaking of to the crushing and penetrating effects; the iron plate has to do all the work. The wood is only a medium for transmitting the blow to the ½-inch skin plate and the ½-inch angle iron frames which form the hull. In this arrangement there is nothing at the back of the armour plate to aid it in repelling the blow. The 4½-inch plate is placed under the most favourable conditions for being punched through by the missile. The perfect analogy of the impact of shot to the punching process was exhibited by the performance of

Note.—Page 237, line 9, for "point" read "points;" line 29, for "lest" read "left;" page 238, line 5, for "equally defects" read "equal objects;" second column, line 32, for "posts" read "ports;" and line 41, for "120 to 150" read "120 or 150."

the Whitworth flat-headed bolt, which cut a clean hole through the 4½-in. plate, as clean as if it had been under a punching machine. Mr. Whitworth claims by his method to cut a core out of the plate, and at Shoeburyness he did it neatly, to the astonishment and dismay of the "Warrior" party. Let it be only well understood that to project bolts made of hardened metal against iron plates is the same thing as to drive a punch through a boiler plate, and all doubt and hesitation as to the right mode of keeping out or breaking up shot will be adopted. The girder principle, "*quoad*" *penetration*, will be abandoned, and the means which would prevent a punch forcing its way through a boiler plate will be followed. If the proposition were to prevent a 1-in. punch penetrating a ¾-in. plate, would any man in his senses place it upon a wooden plank? Certainly not; for if he did the machine would drive the punch through the iron. But if an additional thickness of iron were placed under the plate, or across the orifice of the die, the punch would not penetrate the plate, and probably would be broken if the machine were powerful enough to resist the strain of the effort. This lesson is very simple, and ought to be instructive. It indicates the kind of resistance which should be opposed to shot, and the support which the armour plate requires *locally* at all parts of its back surface. It settles the point that wood is not the material to be used as backing to iron armour. I have before mentioned the law which governs the action of a punching machine. The diameter of the punch, being of steel, must equal, it ought to exceed, the thickness of the plate. If these proportions be observed the machine will do its work. Hence shot, 8 or 6 inches in diameter, projected with sufficient force, ought to and must pierce through a 4½-inch plate, with no support but wood at the back. The explosive force of gunpowder is the machine; the shot is the punch. There was, then, nothing surprising in the work done by Whitworth's flat-headed and hardened punches. Similar projectiles of larger diameter, and fired with sufficient charges, will pierce through much thicker plates if fixed upon wood, and even the 5½-in. plates of the "Royal "Sovereign," which the *Times* of Monday last, with its usual flourish of trumpets, tells us will be backed with 3 ft. of solid timber, will not save the wooden cupola ship from being a prey to the liquid fire which may be communicated to her hull by explosive shells, charged with molten iron. I I trust the supreme Government, if not the Admiralty, will listen to a warning voice in time, and before it proceeds further in the reckless system of iron-casing ships with plates on wood, it will pause to make conclusive experiments with different kinds of backing calulated to prevent projectile punches being driven through armour plates.

By the omision of a few words not very legible in the copy, it is printed in my last letter that "Si William Armstrong is superseded." What I wrote was "the supply of "Sir William Armstrong's naval gun (meaning the 110-pounder) is suspended." The former statemet may be true; if it be not it ought to become a reality, for it is an indecorous anomly, prejudicial to the service and unjust to manufacturers of ordnance, that the director o artillery, the arbiter of the class and make of guns adapted for both service, should be the *virtual* Government inspector of guns of his own invention manufactured at Woolwich, and the *quasi* Government contractor for he supply of the same guns, which the natin is bound to take into stock on a large scale for many years, under a penalty of £80,000.

Surely when Parliament assembles the Armstrong gun system, the Armstrong appointment, and the Armstrong contract, will undergo a scrutiny. In the mean time I will lend my feeble aid to keep these questions alive. The necessity of incessant vigilance is proved by an insidious paragraph in the *Times* of the 20th instant, which deliberately announces that "Armstrong 150-pounders, such as that one "*tested* against the *famous* Warrior target, will "form the armament of the 'Royal Sovereign.'" On reading this sentence I rubbed my eyes and read it again with amazement. Mark the double note of admiration "the *famous* Warrior target," and the implied prowess of the gun "*tested* against it." Let us turn to the *Times* of last week, in which the same hand writes, that the 150-pounder Armstrong having burst, could not be relied on, and moreover, it was too heavy to be used as a naval gun. But in the *Times* consistency is set at nought. I last week exposed the absurdity of its assertion that "a gun of 95 cwt. was the heaviest "that could be worked with success, or even "safety, on board a floating vessel." It now announces that 12-ton Armstrongs are to form the armament of the "Royal Sovereign," and this proves how correct I was in stating that "if the gun tested at Shoeburyness had not "burst, the Admiralty was prepared, with "much boasting of its tremendous power, to "announce its intended adoption as part of "the armament of the Warriors and North-"umberlands."

I am glad to see an intelligent correspondent of the Mechanic's Magazine, Mr. St. John Vincent Day, has taken up the question of Naval Armour. He is quite right in his criticisms of Mr. Richardson's deflective shield system. But the deflecting plan is altogether a mistake if applied in any form but the *continuous* circle or inclined plane. Mere deflecting projections, instead of offering any advantage, are sources of weakness, by presenting protruding points to be more readily shot away, and facilitating the destruction of the armour piecemeal. Mr. Day submits a plan which in principle is the counterpart of Mr. Roberts and Mr. Westwood's angulated systems, both of which were tested in the shape of trial targets unsuccessfully. Mr. Day wisely does not accept the responsibility of contriving a fastening. There lies the difficulty. Without an efficient fastening no form of plate is available. If that gentleman will exercise his ingenuity, and invent a fastening which will hold plates effectually against the shock of cannon balls, he will render a public service.

CIVILIAN.

INTERNATIONAL EXHIBITION. JURY REPORTS.

CLASS VIII.—MACHINERY IN GENERAL.

(*Continued from page* 244.)

General Explanations and Remarks.

M. Lecointe (France—1,166) has obtained a simplification still greater: his apparatus of pumps and cisterns can supply twelve presses. It consists of two force-pumps, the contents of which are led into a reservoir of variable capacity by the play of a plunger moving vertically, weighted to 1,200 or 1,400 lbs. to the square inch. It is this reservoir which distributes the water to the presses at this constant pressure. If the pumps furnish more water than is used, the regulating piston, arriving near the extremity of the stroke, raises a balance weight, the action of which immediately cuts off the action of the pumps. The power returns as soon as the piston of the reservoir is lowered; but this return of power is combined in such a way that it takes place only at the commencement of the stroke of the piston, so as to drive the water with slow velocity at first—essential to the preservation of the machine. The mechanical regulator is ingenious; but it is advisable to avoid the noisy shock of the connecting rod against the clutching lever, which continues so long as only one of the pumps is in action. With the exception of this objection to a matter of detail, the machine of M. Lecointe presents a very important progress in the production of hydraulic presses, and the success which this machine has obtained in a great number of works is perfectly well deserved.

Water-meters, &c.

Water-meters are of many different constructions. That of Mr. Siemens (United Kingdom—1,987), which was to be seen in the Exhibition of 1851, consists of a small turbine traversed by the water to be measured. It remains to be decided by well-authenticated trials whether this instrument registers accurately under the different pressures with which water may have to traverse it.

The other systems of meters consist of filling with water a constant capacity, and registering the number of the operations. That of Mr. Jopling, exhibited by Messrs. T. Lambert and Sons (United Kingdom—1,903), is of very simple construction. It is composed of two equal parallel cylinders, of which the pistons work together in the same direction, the piston rod of each piston regulating at the extremity of the stroke the admission of the water into the neighbouring cistern. All the water must pass through one or the other of these two cylinders; and the number of oscillations registered measures the quantity of water which has passed. The cylinders are enclosed in a case of cast iron, so that the pressure is the same at the exterior as the interior of the cylinders, and its influence on the play of the machine is nearly annihilated.

The Manchester Water-meter Company (United Kingdom—1,923) exhibit several water-meters. One of them is provided with only one cylinder, in which the introduction of the water is regulated by a system of two pistons, which are alternately driven in different directions by a slide, the position of which is changed by the piston rod of the large piston at each end of its stroke. Among the other water-meters of the Company may be seen one (Frost's patent) without packing, which will work with warm water, for the filling of steam-boilers. It is composed of two pumps, formed each of a rectangular box, moving horizontally in the right angle formed by two fixed planes. A partition fixed perpendicularly to the intersection of the two planes, and filling the section of the box, performs the office of a fixed piston, and separates the two cavities of the box, which fill alternately, as they are extended. The box slides in grooves adjusted on the fixed planes, each governing the slide valve of the other. It would be very desirable that regular experiments should be made with these instruments, which would be very rapidly adopted by the public, could they confide in the register of the machines.

M. Sacré (Belgium—277) has exhibited a hydrometer for distilleries. The liquid is measured as it leaves the still, at the same time that a small quantity of liquid, variable at pleasure, is preserved at each measuring, and conducted into a special receptacle, which allows of recording readily the mean density of the liquid distilled.

Section II.—Cranes.

The principal kinds of machines for lifting exhibited are either cranes or jacks.

With the cranes are ranged those called Derrick cranes, presenting generally an extended basis, and consequently great stability. Cranes properly so called are either fixed or movable, worked by hand, steam or water. We remark in the two first classes the system of M. Neustadt, exhibited by J. F. Cail and Co. (France—1,141), and C. Fauconnier (France—1,161), which con-

sists in applying to cranes the Galle chain. This chain, formed of plates of wrought iron united by pins, has no forged joints, and presents a very great solidity. It adapts itself to the teeth of a pinion, and the free extremity of the chain is received into a box or directed into a sheath. This system presents over the others the advantage of doing away with the drum and one of the cog wheels, seeing that the diameter of the pinion is about one-third of that of the drum; of avoiding the oblique winding of the chain, and consequently of notably simplifying the construction of cranes. An experience of seven years has confirmed the use of cranes with the Galle chain. Nearly 500 of them have been constructed, and are used in large establishments. Amongst the most important are those of the Imperial Marine of France.

A crane moved by hydraulic pressure forms part of the exhibition of Sir William Armstrong and Co.(United Kingdom—1,785), and which also appeared in the Exhibition of 1851. The drum is totally suppressed; the chain of the crane when it reaches the head of the vertical standard is passed over pulleys; one of the pulleys is fixed and the other is set in movement by a piston of a hydraulic press. The rotation of the crane is also effected by the pressure of water. This crane is suitable for a locality where water is distributed at a high pressure. It can be fed from a high-pressure hydraulic reservoir, the reservoir itself, fed by force-pumps driven by steam furnishing an advantageous means of replacing the continuous work of the machine by the intermittent work of the crane. The Armstrong system comprehends also a capstan moved by water under high pressure. Three pumps are thus put in motion, and work together on a horizontal shaft, carrying a conical pinion, which works against a wheel fixed at the base of the capstan.

Messrs. Ransomes and Sims (United Kingdom—1,961) have exhibited a portable steam-engine which can act as a steam capstan. A winding drum is placed beneath the boiler; it is driven by a conical-toothed wheel, put in motion by the steam-engine situated over the boiler. The whole of this arrangement is ingenious; but it may readily be understood that this machine cannot exercise very great power. The machine exhibited could only raise 25 cwt. The most useful application of it would be in the raising of building materials.

The hydraulic lifting jacks, already seen at the Exhibition of 1851, have become more numerous. In those of Messrs. Adamson and Co. (United Kingdom—1,780), the oscillations of the lever in raising are lessened by an angle block which butts against the head of the jack. It is only by moving the lever laterally on its axis that the stopping of the operation is prevented, and that the water from the bottom of the press is allowed to pass into the head of the jack, causing at the same time the lowering of the object lifted. With the machine of Messrs. Tangye Brothers and Price (United Kingdom—2,002), the lowering is obtained by a special screw. These instruments are simple and offer great advantages over those with rack wheels.

We must also draw attention to the crab of Mr. Winand (Belgium—28), set in motion by an endless screw, which can guide the gearing but cannot be moved by it. The lowering of the weights can only be obtained by turning a handle in the opposite direction, or by unwinding the screw when a rapid movement is desired.

SECTION III.—PILING ENGINES.

The Jury have granted no awards in this section.

P. LUUYT, *Reporter.*

SECTIONS II. & III.—REGISTERING INSTRUMENTS, AS GAUGES, INDICATORS, AND TELL-TALES.

Great improvements have taken place of late years in articles under these heads, and have thereby contributed greatly to reduce accidents in steam-boilers, by accurate notation of pressure, height of water, &c. The steam-gauges exhibited are in most cases constructed with discs of thin metal, corrugated and plain, secured and made steam-tight at the outer edge, the pressure acting upon the surface, and the amount of deflection is communicated to a movable pointer, which indicates upon a dial the exact amount of pressure. Others are constructed with diaphragms of india-rubber, the pressure being met with spiral or volute springs, and the motion communicated as above. The bent tube manometer of Mr. Bourdon is a most ingenious and correct indicator of pressure, and under all circumstances the best in the Exhibition. Indicators and tell-tales of simple construction and practical utility are well represented. For the most part these are automatic, being self-acting for the regulation of feed-water, and giving notice by whistle of conditions where it is necessary to call attention.

Allen, Harrison and Co., Manchester (United Kingdom—1,782).—Gun-metal fittings for steam-engines. Medal awarded for good workmanship and general excellence. This firm exhibit a very excellent safety plug for steam-boilers; a valve seat is placed or fitted into the boiler flue over the fireplace, having a lid or valve with perforations filled with metal fusible when not covered with water.

Frieake and Gathercole, Mark-lane (United Kingdom—1,857).—Salinometers, telegraphs, indicators. Medal awarded for good workmanship, &c.

Routledge and Ommaney, Salford (United Kingdom—1,972).—Engine-pumps, boiler-feeders, magnetic machines for separating iron and brass. Medal awarded. Practical utility. A very useful and efficient boiler-feeder is exhibited by this firm, which may thus be briefly described:—A small, close cistern (through which the feed-water passes) is placed in connection with the boiler; steam is first admitted into the cistern and afterwards condensed with a small quantity of cold water, thus forming a vacuum, which by a self-acting arrangement causes the cistern to fill with water from the hot-well of the engine or any convenient source. Steam is then admitted so as to act with equal pressure to that in the boiler, and the water enters the boiler by its own gravity; this apparatus is very perfect in its action, and will feed with water at any temperature below 200 degrees.

G. Salter and Co., West Bromwich (United Kingdom—1,978).—Spring balances, dynamometers, pressure-gauges, &c. Medal awarded. Excellent workmanship, practical success. These owe their efficiency to well-tempered springs, and are not surpassed. The pressure-gauges act by means of the steam or the water pressing against an india-rubber plate, on which lies a metallic plate with rod in connection with the mechanism, and which is kept down by one of Salter's springs.

J. Chandler, Mark-lane (United Kingdom—1,817).—Flat glass water-gauge for boilers. Honourable mention.

Smith Brothers and Co., Nottingham (United Kingdom—1,991).—Pressure and vacuum-gauges. Honourable mention. These gauges are on the priciple of Salter's, excepting that a volute spring instead of a spiral is used, a diaphragm of india-rubber preventing the passage of steam.

F. Wise, Adelphi (United Kingdom—2,028).—Feed-water regulator, indicators, alarm for steam-boilers. Honourable mention. The regulator for steam-boilers consists of a copper float attached to a lever within the boiler; to this lever is connected a small gun-metal slide, which rises and falls with the float, and when the water level is slightly in excess of the proper height, opens a port whereby air or steam is admitted to the suction pipe or working barrel of feed pump, thereby suspending its action until the water is below or at its proper level.

J. White, Borough (United Kingdom—2,021). —Engine oil-feeders, &c. Honourable mention.

E. Bourdon, Paris (France—1,156).—Manometers, barometers, injectors, centrifugal pumps, &c. Medal awarded. Originality of design; good workmanship of the several articles; practical success of manometers and barometers. Mr. Bourdon has a very interesting exhibition of pressure-gauges, vacuum-gauges, barometers, &c. These are based on the principle of the distortion of tubes having elliptical sections by an internal pressure, and torsion or twisting by external pressure. In these pressure-gauges a curved tube of elliptical section is fixed at one end, both ends being hermetically sealed. Steam is admitted, which has a tendency to straighten or uncoil the tube; the other end is attached by a small link and lever to an indicating finger. Mr. Bourdon also uses a twisted tube, in the form of a quick-threaded screw; steam being admitted has a tendency to untwist the tube, and the motion is communicated to the indicating finger as before.

A gauge for very high pressures is made by having two curved tubes, filled with water, in connection, one being secured in a vessel so as to be acted upon externally. This causes a pressure to act upon the exposed tube internally, and the movement is communicated to dial, as before.

Mr. Bourdon also exhibits several modifications of a mode of raising water by jets of steam, which are in all respects on the principle of Giffard's injector for feeding boilers.

L. J. F. Desbordes, Lyons (France—1,100).—Manometers, pyrometers, barometers, &c. Medal awarded. Good workmanship; practical success.

Desbordes and Roudalt, Paris (France—1,139). —Manometers, &c. Honourable mention. These manometers act by pressure upon a flexible disc, which gives its indication upon a dial by means of a lever and toothed quadrant working into a small pinion on the pivot of indicating needle.

A. Achard, Paris (France, 1,023).—Electro-magnetic safety apparatus. Medal awarded. Ingenious and original design. This machine is very perfect in its action; and in addition to its being a self-acting regulator of the supply of feed-water to the boiler, gives notice by ringing a bell of any derangement under the following circumstances:—

When the water is too low or too high.
When the steam is too high.
When the feed-pump is out of order, and
When the apparatus itself ceases to act.

F. T. Moison, Mouy (France—1,171).—Dynamometers. Medal awarded. Original design; practical utility. The dynamometers of Monsieur Moison are very ingenious and practical; the driving pulley gives motion to the machine to be tested, through three bevel wheels in the usual manner, one being placed upon an axis at right angles with the other, its fulcrum being the shaft upon which the other two wheels revolve. The power is registered by dials acted upon by the spindle upon which the intermediate bevel-wheel is placed. Monsieur Moison also exhibits a steam-engine and water-wheel governor; the former acts much in the same manner as the dynamometer, a fly-wheel being driven by wheels fixed upon a balance lever, upon one end of which is a weight tending to depress it. When the speed of the engine is such as to overrun the fly-wheel, the weight is raised and the throttle valve closed; the latter is a pendulum or ball governor, running horizontally, having a spring to counteract the tendency of the balls to expand. On one end of the governor spindle is fixed a spur-wheel, which gears into another running loose upon a shaft, parallel with governor spindle; on the opposite end is a conical pulley, giving motion by means of a strap to another pulley which runs loose on the same spindle as that on which the spur-wheel is placed. The strap is moved by means of the ball governor, giving a varying speed to the driven cone pulley. The driven spur-wheel and driven pulley are connected by means of an intermediate bevel-wheel, and when the speed of one exceeds that of the other, a motion is communicated so as to open or close the water sluice.

David Brothers and Co., Port Quentin (France —1,106)—Instrument to test the strength of thread. Honourable mention.

Dedieu and Co., Lyons (France—1,159).—Manometers. Honourable mention In this the

steam acts upon a disc of metal, motion being communicated to the indicating needle by an eccentric and levers, a coiled spring preventing any play.

P. Renaud, Nantes (France—1,141).—Float for steam boiler, and alarm. Honourable mention.

Lethuillier-Pinel, Rouen (France — 1,140).—Magnetic indicators of water level. Honourable mention. In this a magnet, moved by a float inside the boiler, causes a small light steel roller to rise and fall outside a face plate on top of boiler, and indicates correctly every change of level of water.

J. C. Gore & Co., Jamaica Planes (United States—36).—Belt shifter. Medal awarded. Originality of design; probable utility. A very simple and effective invention. The belt shifter is moved and locked by one motion, thereby preventing the possibility of accidental movement so as to prevent the starting of any machine at an improper time.

S. Elster, Berlin (Prussia—1,395).—Gas-testing apparatus. Medal awarded. Originality of design, good arrangement, and good workmanship.

A. Sacré (Belgium—277).—Hydrometer. Honourable mention.

Near & Co., New York City (United States—27).—Dynamometer. Good arrangement; practical utility. Medal awarded. This is a very ingenious machine, but difficult to describe without a drawing. Two pulleys are mounted upon a spindle, one being connected with the motive power, the other with the machine to be set in motion, one being loose, the other fast; the former exerts its power upon an inclined plane, which acts longitudinally upon two spiral springs, and these indicate their pressure on a scale or counter fixed to the framework of the machine. This counter, besides being actuated by the force and motion of the driving pulley in a uniform manner, is caused to revolve in an increasing ratio as the pressure or force increases, by means of a cone, which advances or recedes with the spiral springs, and which gives its motion to the counter by a friction roller.

Böckenhagen (Mecklenburg-Schwerin, 37).—Spirit gauge. Honourable mention.

E. Drewitz (Prussia—1,295). — Alcoholometer for quantity and strength. Honourable mention.

Schäffer and Budenberg (Prussia — 1,316).—Manometers; steam-engine fittings. Honourable mention. These manometers act by pressure upon a corrugated plate of metal, and give motion to the needle by a lever and toothed quadrant and pinion; they have proved very effective in practice, and can be relied on for their accuracy.

O. M. Hempel (Prussia—1,404).—Steam-pressure gauge. Honourable mention.

Watremez and Kloth (Prussia — 1,325). — Black's safety apparatus for preventing the bursting of boilers. Honourable mention.

D. A. Löhdefink (Hanover — 379).—Manometers. Honourable mention.

J. J. Gutknecht (Switzerland — 154).—Apparatus to measure spirits and water; dry gas meter. Honourable mention.

Waltjen and Co. (Bremen—6).—Friction balance and oil test. Medal awarded. Good design, practical utility of oil test. This apparatus is intended to determine the description of oil best suited for lubrication of shafts at certain given velocities.

A shaft supported on two bearings is fitted with a sliding friction pulley, driven from a friction disc, placed at right angles to the shaft. The sliding friction pulley is movable from the centre of the disc to its circumference, so as to allow of increasing or diminishing the speed. One end of the shaft is fitted with a worm gearing into a worm wheel, which registers the number of its revolutions. The other extremity of this shaft is fitted with a collar, and upon this collar the balance disc is supported by a segment of a step. The balance is weighted by two pieces of metal of equal weight, suspended from the two ends of a strap which passes over it. On each side of the balance a knob is cast to the circumference, one of which knobs is bored out to receive a cylindrical weight, which screws in and out. The various parts of the balance are so adjusted that its point of gravity falls a little below its centre, and a hand fixed at the lower extremity of the balance shows when it is in a vertical position and accurately balanced. The oil-cup passes through the centre of the step segment to the point of contact with the collar. The apparatus being put in motion, the smallest amount of friction will tend to raise that side of the balance which is fitted with a sliding weight, which is thereupon screwed out so as to increase the weight on that side until the friction is counterbalanced, when the scale marked on the sliding weight will indicate in pounds and ounces the amount of friction on the collars at the given speed with the oil used. On testing various kinds of oil at the same speed, it will be easy to ascertain which quality produces the least amount of friction.

J. Adcock, Dalston (United Kingdom—1,781).—Distance indicator for wheel carriages. Honourable mention. A small air cylinder is fixed vertically to the axle of the carriage near the wheel, and communicates by means of a non-flexible india-rubber tube, with a second air-chamber, being part of a clockwork which renders the number of revolutions of the wheel. The boss or nave of the wheel is fitted with a curved arm or rod, which after each revolution of the wheel depresses one arm of a bell-crank lever, the other arm of the same acting upon and depressing the piston rod, which is attached to the centre of an india-rubber disc with which the cylinder is fitted; on the disc being thus depressed, a portion of the air in the cylinder will be forced through the tube to the air-chamber of the clock-work, and inflate the india-rubber disc or bag of the same. The centre of the disc is connected with a pall of a ratchet-wheel, and each time the air is forced into the air-chamber the pall will rest upon the ratchet-wheel and cause it to move forward one tooth, and thus register by means of the clock-work the distance passed over by a revolution of the wheel. The arm of the nave having passed the arm of the bell-crank lever, the disc in the cylinder will, by its own elasticity, or by means of a spring, rise and again admit the air into the cylinder, the same body of air being passed to and fro between the cylinder and the air-chamber, and no valves being required. The apparatus is at once simple and effective, and not liable to get out of repair.

R. and L. R. Bodmer (United Kingdom—1,801).—Safety valve. This being exhibited by a Juror could not be made the subject of an award, but the Jurors wish to record their appreciation of it. The peculiarity of this valve consists in the valve edge being raised by a column of steam of water, entirely independent of the escaping steam; a tube formed in the centre of the valve is connected by means of a pipe with the steam space or water of the boiler; at its upper end this tube is enlarged, and forms a piston of the diameter of the valve; and the valve cap, made in the form of an inverted cylinder open at the bottom, fits on the piston, and rests on the valve seating in the usual manner. When the steam pressure exceeds that to which the cap is weighted, the steam or water, acting upon the end of the inverted cylinder valve cap, will lift the same in proportion to that pressure; but on any sudden accumulation of steam taking place, the valve will at once open to its full extent, and immediately relieve the boiler of its surplus pressure.

With a slight modification, valves on this principle can be constructed with a lifting area of exactly one square inch, less or more, whilst the diameter of the valve may be three, four, six, or more inches.

These valves are particularly adapted for being weighted direct, by means of weights or springs.

F. Normand, Paris (France — 1,179).—Improved method of correcting the error of the universal joint in transmitting motion. Medal awarded. Originality of design, practical success.

J. N. Mauzaize, sen., Chartres (France—1,197).—Engaging and disengaging gear.

The reporter of the foregoing articles under Subdivions II. and V. has preferred giving a short general report, and has added a more detailed description under the head of each, where he considered the articles deserve special notice.

J. HICK, Reporter.

APPENDIX TO CLASS VIII.

SPECIAL JURY FOR FIRE-ENGINES.

J. F. Bateman, F.R.S., London; Civil Engineer.
Capt. Bent, London; Superintendent of Fire Arrangements in the Exhibition.
W. M. Brown, London; Superintendent of Westminster Fire Brigade.
Earl of Caithness, London.
J. Hawkshaw, London; Civil Engineer.
C. Jenny, Austria; Councillor of Mines in the Imperial Royal Academy of Mines at Schemnitz.
P. Luuyt, France; Engineer to the Imperial Commissioners of Mines.
J. E. McConnell, Wolverton; late Locomotive Superintendent of the London and North-Western Railway.
O. Pihl, Norway; Civil Engineer.
W. J. M. Rankine, Glasgow; Professor of Mechanics in the University of Glasgow.
Capt. Shaw, London; Superintendent of the London Fire Brigade.
Duke of Sutherland, London.
F. B. Taylor, United States; Mechanical Engineer.
H. Thomas, Zollverein; Manufacturer.
H. Tresca, France; Professor of Mechanics, President of the French Institute of Civil Engineers.

Report of the Special Committee of Class VIII. on Fire-Engines.

The respective merits of the engines were considered with reference to the following points, those engines being recommended for medals or other approval which combined excellence in the greatest number:—

1st. The weight and size of engine.
2nd. The quantity of water delivered at certain heights and distances.
3rd. The depth from which the water was drawn.
4th. The power employed.
5th. The material, price, and general construction.

Due notice having been given of the time and place of experiment, the mode of procedure, the rules to be observed, and the tests to which the engines would be submitted, the following gentlemen attended a meeting for previous consultation, and expressed themselves perfectly satisfied with what was proposed:—

Messrs. Blinkhorn and Shuttleworth;
M. Letestu;
Messrs. Merryweather and Son;
Mr. Henry Roberts;
Messrs. Shand and Mason;
Messrs. T. Warner and Sons.

At the same time Messrs. Shand and Mason and Messrs. Merryweather and Son requested that time should be allowed them to prepare their respective steam fire-engines for the trial.

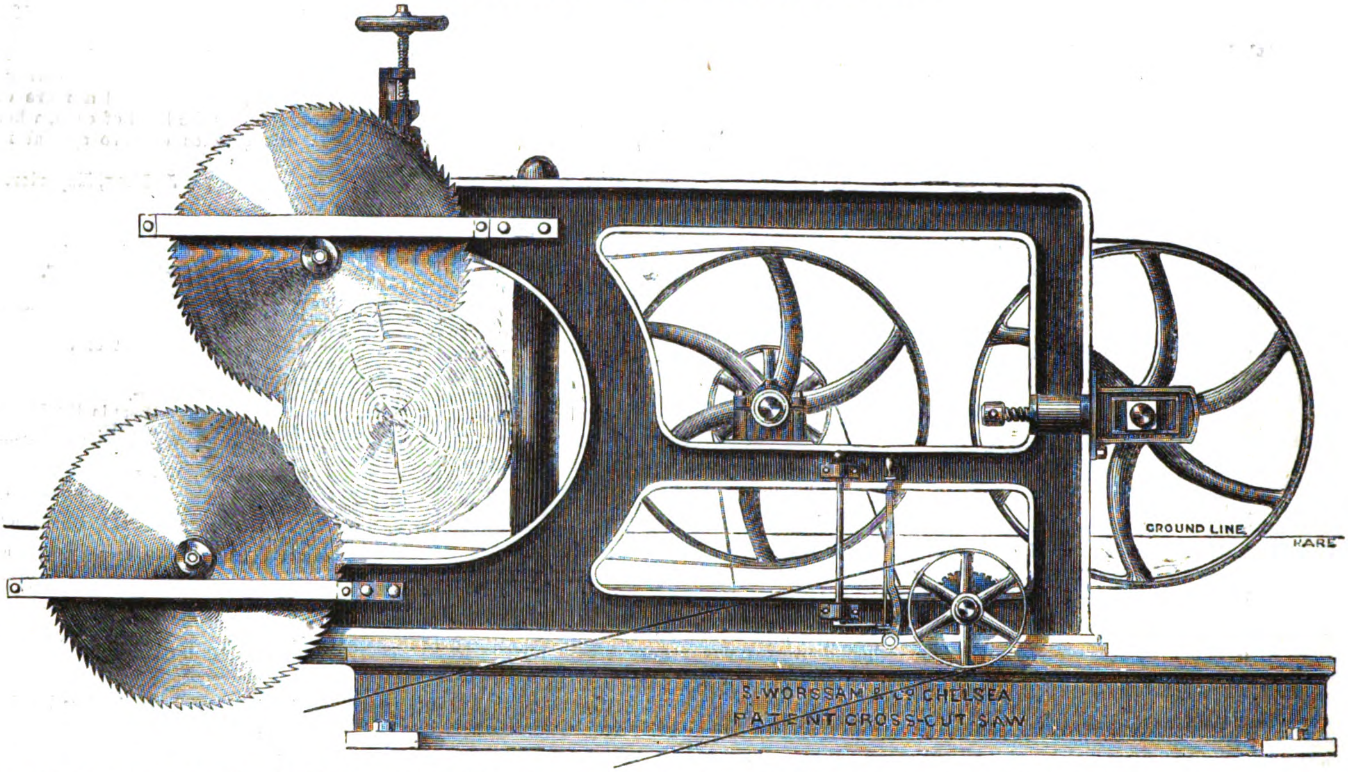
The distinctive feature in these trials, as compared with former experiments, was the measurement of the water after delivery, which was accomplished in the following manner:—

Water targets were constructed, consisting of hoods of canvas, with a circular opening of six feet, that space being considered the utmost limit to which a jet can spread without being dissipated into spray, and so becoming useless when projected on a fire.

These targets were elevated on a horizontal cross pole, which was raised to any required elevation on posts erected for the purpose. To each target was attached a tail or shoot, also of canvas, through which the water which struck inside the target was conducted into a gauged trough or tank which stood below, and in which the quantity delivered was read off from a graduated index.

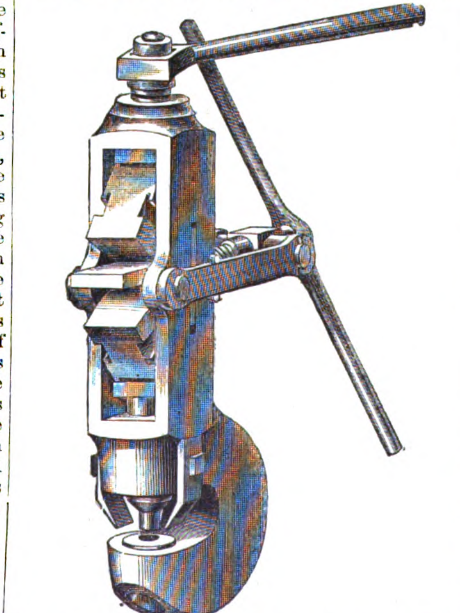
To be continued.

WORSSAM AND CO.'S CROSS-CUT SAW.



The above is a side elevation, half-inch to the foot scale of a machine we lately inspected, for cross-cutting large logs of timber, and made by Messrs. Worssam and Co., of Chelsea. This particular one was ordered by Captain Schwartz, Russian Imperial Commissioner in England, for the Government dockyards at Cronstadt. The saws are 42 in. in diameter, having a traverse of 4 ft. 6 in., the counter-shaft making 100 revolutions per minute. The whole machine weighs about 3 tons, and requires an average of six horse power to drive it. It is intended to cut round or square timber up to 30 in. in diameter. The cut is made by two circular saws working in the same plane one above another, the lower half of the log being cut by the bottom saw, and the other half by the top one. The saws, together with the arrangement for driving them, are attached to a strong framing of cast-iron, which slides upon a fixed bed, the whole being worked backwards and forwards by a self-acting motion, driven from the spindle which carries the lower saw. The upper saw spindle is fitted to a slide, somewhat like the arrangement for raising and lowering the tool-slide of a planing machine, which therefore permits it to be raised or lowered to take saws of various sizes, or to take up the wear of the saws. By the peculiar arrangement of driving both the saws from the same band, running over a tightening pulley, the strap can always be kept at the required tension. The machine is driven from an intermediate shaft, which can be fixed either below or overhead, the first arrangement being the preferable one. This shaft is attached to a weighted framing of cast-iron, working on a hinge joint, which allows of its rising and falling to adapt itself to the motion of the sliding carriage. Two oak columns are fitted into cast-iron shoes in front of the machine, on each side, to protect the saws from the timber when being rolled into the required position. One new thing about this machine is the arrangement to keep the saws steady. In addition to the usual longitudinal packed guides, shown in the engraving, there are other peculiar guides to support the saw before it enters the wood. These guides are on hinges, so that they may fold down in a vertical direction when they come against the timber. Of course, the principal and most important novelty about this wood-cutting tool consists in the use of the two smaller saws instead of one large one; and it certainly is a very simple and ingenious way of getting over the manifold objections to a large saw. To do the work of these 42-inch saws, a 7-feet diameter saw would be required, costing £123, wholesale price, measuring in thickness No 10 wiregauge (about $\frac{1}{4}$ inch), being difficult to get sound, and also liable to wobble while doing its work. One 42-inch diameter saw costs £9, measures one half the thickness of a 7 ft. one, and takes therefore so much the less power to drive it, there being at the same time much less risk in its use and its manufacture, while the fact of less power being required, enables a lighter and therefore cheaper frame to be used.

COOK's PATENT PORTABLE HAND PUNCH.



This machine, which weighs about 50 lbs., punches holes in $\frac{5}{8}$-in. boiler plate; and will make ten holes whilst a drill makes one. The machine works well, and is so simple in its construction that a boy can use it.

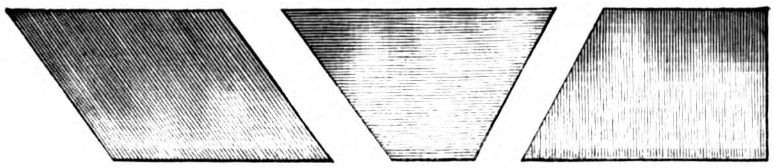
In using these punches attention should be paid to the following instructions:—With a centre-punch a small hole should be punched in the plate, for the centre in the face of the punch to drop into. The back nut of the punch should be turned backwards until the T piece presses firmly against the cams, carrying them to the front of apparatus until the faces of the hinge joints in front are in contact. The cams being in this position their shortest radii are opposite each other. The top screw should then be turned upwards, raising the whole of the interior works of the punch sufficiently high to admit the plate under the punch. The centre point on the punch having been placed in the centre mark on the plate, turn the top screw downwards, pressing the face of the punch firmly and hard upon the plate. Now turn the back nut, so as to draw the wedge towards the operator; this will draw the cams with it, bringing their longest radii opposite each other, until the faces of the hinge joints at the back are in contact. The back nut must on no account be turned beyond this. The top screw must now be turned downwards again, which will force the burr out of the plate. After this, turn the back nut backwards, forcing the T piece forwards, and bringing the cams to their first position; then raise the top screw, which will draw the punch out of the work, when the instrument will be ready for the next operation.

Further information may be obtaiued from Messrs. Ransome & Co., Essex-street, Strand.

The Building News says that Melbourne has been provided with water-works at a cost of about £820,000. Though the population of Melbourne is only 123,000, the supply, which is at the rate of 100 galls. per head per day, is estimated to be sufficient for 200,000 persons. This affords a striking contrast to the quantities supplied in England to the inhabitants of our principal and more thickly-populated towns. London is only at the rate of 20 gallons per head; Nottingham is 40; while Wolverhampton and Liverpool have only 11 gallons per head daily. The consequence is that the supply of water in Melbourne is more than sufficient for the wants of the inhabitants, and will continue to be so for years to come.

IMPROVEMENTS IN THE CONSTRUCTION OF WAR VESSELS, FORTS, &c.

Fig. 1.



These improvements consist in the construction of the hulls of ships or such parts as may be required, cupolas and forts, of iron or steel, or both, in one mass by welding together the slabs or plates necessary for their construction *in situ*. Riveted joints, separate armour plates, and, when the metal is sufficiently thick, both ribs and wooden lining may be dispensed with; at the same time, it is said by the inventor that structures of greater stability, sounder workmanship, and of more enduring powers, will be produced than those made upon any previous plans. The metal used may be of any thickness, but need not be in pieces of more than one-fourth the area of ordinary loose armour plates, whereby economy in price, and facility in handling, will be among the advantages obtained.

The principal conditions, plant, and processes, necessary for carrying out this invention consist of:—

1. Tough iron or steel slabs, or plates forged of suitable thickness, and generally to the shapes shown in fig. 1.

2. The usual stationary and portable templates showing the configuration of the work to be executed.

3. The progressive erection of strong and roomy stages, both inside and outside of the intended hull or other work, on which are placed tramways for the transit of trucks and small locomotive steam-hammers; the latter made so as to deliver their blows on the slab to be welded in any required direction.

4. Planing machines, by which the edges of the slabs or other work are serrated or grooved, so as to lock into each other and be expeditiously and equably fused at a depth not greater than one-tenth of an inch, which is found sufficient to make a sound joint. One form of serrations is shown on Fig. 3.

5. Bending machines, to give the material proper forms and curvatures.

6. Suitable guides to keep the welding parts in true position while under the influence of the steam-hammer.

7. Intervening cushions or striking blocks, with serrated and grooved faces, to protect the outer edges of the slabs from injury by the hammers.

Fig. 3.

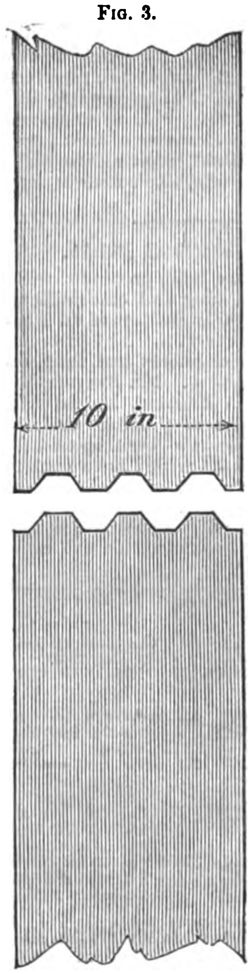


Fig. 2.

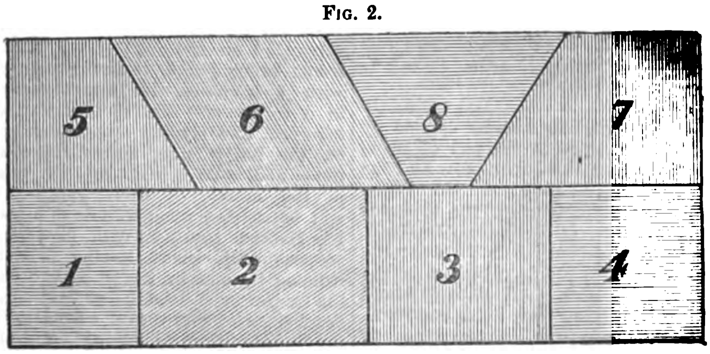


8. Blow-pipes, for the delivery of oxygen gas combined with carburetted hydrogen, of improved construction and sufficient power, and in the requisite forms to weld seams of any thickness, length, and shape.

The apparatus by which the oxygen gas is generated consists of an iron retort, in which oxide of zinc and nitrate of soda are decomposed, their products being chiefly oxygen; there are also a separator and condenser by which the products of distillation of the above ingredients are divided and cooled before the oxygen enters the gasholder. The carburetted hydrogen could be produced by a similar plant, but it is more convenient to take it from the street main gas pipe. These gases are brought together into one flexible tube, constituting in fact, with its improved burner, a movable blow-pipe capable of being regulated, moderated or made to burn with the greatest conceivable intensity, melting even platinum as if it were sealing-wax.

One of the most important facts connected with the present invention is that oxygen gas is *no longer a costly commodity*, being now made at less than 7s. per thousand feet, whereas that from manganese, the only ingredient which formerly produced oxygen, cost from £8 to £10, so that this indispensable gas, made as here described, is the cheapest fuel extant for all purposes requiring an intense and controllable heat, either constant or intermittent, concentrated or diffused.

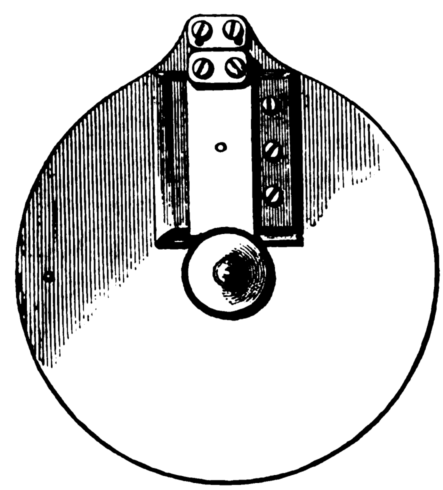
The following examples of making and welding joints by this invention will, it is presumed, satisfactorily attest its practicability, expedition, and trustworthiness. Sufficient materials having been prepared, the gas-holders charged, and all things ready for uniting the metal, the workmen commence on a butt joint, as shown in Fig. 2. No. 1 slab is a little elevated, set on its edge, and firmly fastened to a bed plate. No. 2 slab is fastened on a truck, also on its edge, with its front end projecting a foot or so over the truck towards No. 1, and its other end furnished with a cushion. This truck runs on a pair of V-shaped rails. The front end of No. 2 is run up into the end of No. 1 slab, and adjusted to fit it, and then run back from four to six inches. A light horizontal steam-hammer follows on another truck until its head touches the cushion; in this place the truck wheels are scotched. Fire bricks and lumps are placed on the back and on the top of the gap thus formed by the ends to be united and other open places where it is desirable to keep the heat in. The blow-pipe is now made to send forth its caloric on all parts of the serrations to be united during a few minutes, or until their surfaces are equably fused, when, in obedience to a signal, the steam-hammer pushes No. 2 slab, truck and all, forward, and a few rapid blows from the steam-hammer make the joint. The men with small hammers trim up the exuding metal, and the joint is finished. The united plates are now propped up, the slab truck released, and loaded with No. 3 slab, which is welded on to No. 2 as before described; the same with No. 4, and so the work progresses with facility and rapidity until the required length of a man-of-war's keel, for example, is constructed in one piece.

After No. 5 slab has been lowered by the hoisting gear and the guiding apparatus adjusted, it is raised a few inches, backed with fire bricks, and the whole of its lower edge, also the top edges of Nos. 1 and 2, are fused by means of the blow-pipe, and No. 5, welded on to them by a steam-hammer, which strikes downwards. Then follows Nos. 6 and 7, which are subjected to similar management, the tier being finished by the gravitation of No. 8.

DESCRIPTION OF ROBERTS' ECCENTRIC METAL GAUGE.

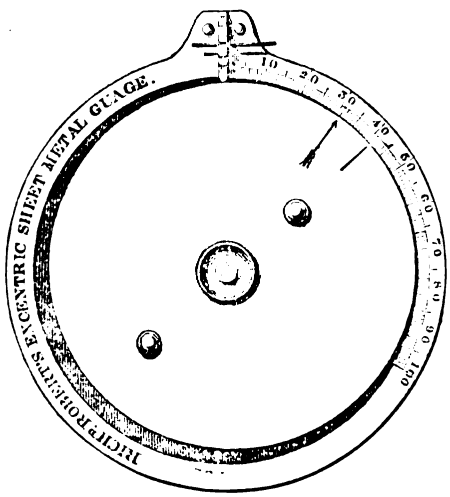
By the Inventor.

A circular brass casting, as seen in the drawing, 4½ in. diameter, having a boss at the back, is recessed in the lathe to the depth of 1-7th of an



inch; the diameter of this recess is 4 in.; concentric with the recess is drilled a hole in the brass casting. A circular plate of steel is procured, about 4 in. diameter and 1-12th thick, in which a hole is drilled about ⅜th in. diameter and 1-10th in. out of centre; into the plate a steel pin is turned to fit the hole in the plate and the brass; the steel pin is provided with a large flange-like head, secured to the plate with three screws; the plate is turned 1-10th in. eccentric to its pin until it will just enter the recess in the brass casting; upon the back of the brass is a steel slide, from which projects upwards through the brass a "steel jaw," which is thrust inwards against the plate by a spring lying at the bottom of the recess. To a lateral projection of the brass is secured a fixed steel jaw, which, when the steel plate presents its largest radius to the sliding jaw, the fixed jaw is secured in contact with the sliding jaw; both jaws must be very

accurately finished, so as to prevent the light passing between them. There are two studs riveted into the steel plate for the purpose of



turning it. The margin of the brass beyond the recess is divided into 300 equal parts, commencing at the centre of the fixed jaw; and as the gauge would be too fine for any practical purpose if marked from the greatest radius of the steel plate, I merely use the centre mark for adjusting the gauge, after which I mark it at 10 points to the right from the longest radius, and call that No. 1, which is fine enough for gauging the finest balance spring. After No. 1 the succeeding numbers increase by accelerating increments up to 75 deg., after which the reverse will be the case. Numbers beyond 75 deg. will seldom be required in the watch trade, therefore the evil will not be of much consequence up to 100 deg., which is as far as is desirable to engrave it.

THE COINAGE OF JAPAN.

The coinage of Japan is at once the most peculiar and the most ugly and inconvenient of any in existence. There are two kinds of gold coin current among the Japanese; one of these, the largest, is known as the Ko-ban, or Copang. It is of a flat oblong form, with rounded ends, and has a series of hieroglyphics stamped upon its surfaces. The length of the piece is 2¼ in., and its width 1¼ in. Its weight fluctuates between 200 and 193 grains English, and its standard of fineness ranges from $\frac{154}{288}$ to $\frac{161}{288}$; its intrinsic value, therefore, varies from 18s. 5d. to £1 sterling. The leaf-like designs which ornament each end of the obverse represent the arms of the Dairi; the characters immediately beneath give the weight and value of the coin, and the name of the mint-master by whom it was struck. In the middle of the reverse is the mark of the general director of the gold and silver coinages, and smaller marks surrounding it at irregular distances show that it has passed through the balances of private individuals, and not been "found wanting."

The second gold piece is of an oblong form, with square ends, and is much smaller than its companion, its length being ¾ in., and its breadth ⅜ in. Its name is *Itchebo* or *itjib*. The weight of the older coin of this denomination is 68 English troy grains, and its standard of fineness is equal to $\frac{669}{1000}$, and its value 6s. 10½d. The present Itchebo of Japan weighs 50 troy grains, has a standard of fineness equal to $\frac{656}{1000}$, and is worth 5s. 10½d. On the obverse is the Imperial coat of arms, and on the reverse that of the mint-master.

The silver coinage comprises four denominations, the first or largest being of the same shape as its richer neighbour, the Ko-ban, but larger. Its length is 3 in., and its width 1⅜ in. It is called the Ita-kane, which, being interpreted, means plate-metal, a most appropriate term. The Ita-kane weighs on an average 1,160 English troy grains; its standard is $\frac{236}{288}$, and its value about 12s. It is decorated with the Imperial arms at both ends, and has its weight, value, &c., stamped in the centre. The reverse side is quite plain. The second-sized silver coin is oblong, with square ends, and its weight is 150 grains. The Chinese words *i fun*, which means *a part*, form the obverse, the reverse being a plain surface. The third and fourth silver coins are oblong also, with square ends, and they are decorated with Chinese characters, which we are unable to arrive at the meaning of. Their respective weights are 37½, and 30 troy grains. The practice of stamping the mint-master's name upon the Japanese coins is singular. During the Saxon heptarchy, however, and even for some time after the absorption of the Heptarchic kingdoms into one State, it was the custom to imprint a moneyer's name upon English coins, in token of their genuineness, so that we need not laugh at the habit of our primitive friends who, like ourselves, may relinquish it some day.

RAILWAYS IN BRITISH INDIA.

The railways of India are being proceeded with, in spite of many engineering and other difficulties, with a speed which is worthy of all commendation, and which reflects the highest credit on the various English engineers and their assistants engaged in the work. Mr. Danvers, the Government Director in England, has recently issued his official report of progress made in 1861, but as many miles have been opened for traffic in the nine months which have elapsed since the 1st of January last, we shall take the liberty of giving our readers, in a tabular form, the probable mileage of the various Indian railways which will be in operation on the 1st of January, 1863:—

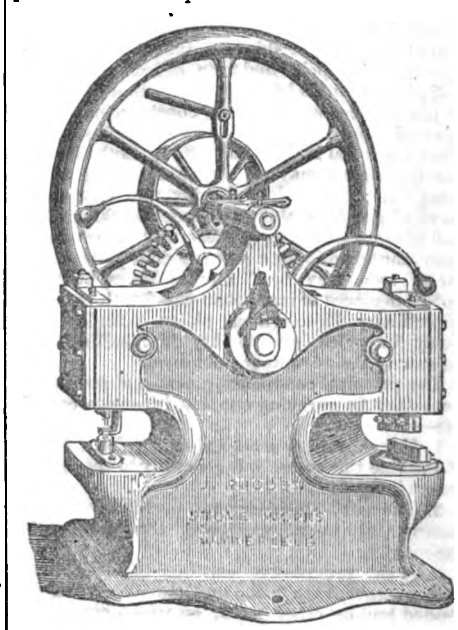
Name of Railway.	Total Length. Miles.	Open on 1st Jan., 1862. Miles.	Additionally Open 1st Jan. 1863. Miles.	Remaining to be completed on Jan. 1st, 1863.
East Indian	1,364	563	496	From Benares to Allahabad and Jubbulpore.
G. I. Peninsula..	1,266	437	219	From Sholapore to Bellary, on Madras side; Julgaom to Nagpore, on the south side, Jubbulpore on north side.
Madras	850	298¾	150	From Arconum to Bellary, and the Bungalore & Neilgherry Branches.
Bombay and Baroda	310	132½	117½	Sixty Miles.
Sinde	114	114	—	—
Punjaub...........	252	—	45	—
Punjaub and Delhi	280	—	—	From Lahore to Moultan.
East Bengal	110	—	110	To be finished in 1866.
Great Southern..	78½	—	78½	—
Calcutta & S. E.	29	—	29	—
Total	4,653½	1,545¼	1,245	1862¼.

Of these 1,862¼ miles, 520 will be opened by the end of 1863; 730 more at the end of 1864; and the rest, embracing the Jubbulpore and the Delhi and Lahore lines, in 1865 and 1866. When we consider the spaces traversed, the obstacles overcome, the distance of India from England, the exposure of English engineers to a hostile climate, and the occurrence of a rebellion in the midst of the work, it is impossible to withhold admiration from the men who, in a comparatively short space of time, have done so much. Before many years elapse it will be possible for a passenger, almost without changing carriages, to go by rail from Kurrachee to Calcutta, thence to Bombay, thence to Madras, and thence to Trichonopoly or Beypore, thus crossing the continent three times with only one break from Kotree to Moultan on the Indus!

Truly this is progress indeed, and the only source of regret in connection therewith is that many, very many, valuable lives have already been, and many more doubtless will be, sacrificed in effecting it.

RHODES' PUNCHING AND SHEARING MACHINE.

The annexed is a sketch of a small punching and shearing machine, exhibited by Mr. Joseph Rhodes, of the Grove Works, Wakefield, in the International Exhibition. It is intended for either hand or steam-power. It shears up to ⅝-in. plate, and it punches up to ¾-in. holes in ½-in. plate. The shears are placed at an angle for bar-cutting, and they take in up to 7 in. from their edges. The punch will take in plate 9 in. from centre.



The pullies or the handle on the fly-wheel, work a pinion driving a large-toothed wheel, on the shaft of which wheel are two eccentrics, each eccentric working a lever on a fulcrum, as shown. The other ends of the levers work the square slides up and down, for either punching or shearing. Either slide can be thrown in or out of gear.

HARBOURS OF REFUGE.

Since our recent article has appeared upon the necessity of constructing additional Harbours of Refuge in this country, our attention has been drawn to a breakwater, invented by Mr. W. Bennett Hays, engineer. One of them was executed some few years ago for the Government of South Australia, but, from unexpected difficulties, arising from the rocky nature of the soil, it has not yet been erected.

It will be constructed in bays of 20 feet, supported on cast-iron screw piles, the platforms being ⅜-inch boiler plate, put together with ⊥ irons on the upper side, riveted on in a transverse direction, and Barlow's rail, inverted, and riveted longitudinally as bearers on the under side, and further stiffened by pipes and bolts connecting the plates together in the middle of their length. The plates will be carried upon frames of bar-iron, 6″ by ¾″, riveted together with cross and diagonal pieces, each plate having a 3½-inch angle-iron on its end by which it will be bolted to the frames, and be supported by small cast-iron brackets, also bolted to the frames. The frames themselves, when in their places, will be bolted to one another, and will rest upon step castings attached to the piles, and be connected to the piles by wrought-iron clips and links. The breakwater will be arranged in the form of a crescent, presented towards the point of the prevailing winds, and is 240 feet in length.—*Building News.*

The Art Union of Glasgow have this year decided to issue, instead of the usual engraving, three photographs of works of art.

Correspondence.

[*We do not hold ourselves responsible for the opinions of our Correspondents.*]

LONDON BRIDGES INVERTED.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

Sir,—The article on the London bridges, extracted from the *Building News*, I have read with some degree of interest, having devoted several years of persevering determination to the subject of embanking the Thames on *both sides*, from Chelsea to the Nore.

I had my attention early directed to the probability of weakening the bridge-piers and arches (by deepening the scour of the stream) when both sides of the river were finally embanked. But I saw an immediate remedy for suggested probable evil. In looking at the reflected bridge, on a bright day, I

noticed the reflection of the bridge in the water, and I considered it gave a capital notion of how to build bridges *for endurance* by constructing inverted arches, as shown by dotted lines of the reflected bridge which would give immense strength and resistance to scour of stream.

Yours respectfully,
W. Austin, C.E.

DEFLECTING ARMOUR PLATES.

Sir,—Will you kindly permit me to reply to the letter of your correspondent, Mr. St. John Vincent Day, that appeared in your valuable paper of the 17th ult. That gentleman appears not to be aware of the extreme difficulty of applying deflective armour to sea-going ships of war. If he would sketch or draw out a complete section of a ship with the construction he proposes on each side he would see immediately the impracticability of it.

The muzzles of the guns should of course be capable of being projected beyond the port sills. To secure this the deck upon which they stand would have to be projected into his wedge-formed shields, making the breadth of the ship at that part 15 ft., or more than the breadth at the line of flotation.

Mr. Joshua Jones, of Liverpool, who patented the form proposed by Mr. Day in 1859 (No. 2,391), dropt the point of the wedge to the line of flotation, producing the celebrated iron angulated ship which has caused so much discussion, and which is really the parent of the whole of the American and other vessels of similar description.

The angulated ship, after considerable hesitation, appears not to have found favour with our admiralty. The late General Sir Howard Douglas thus remarks upon it:—"From the falling in of the sides, to the extent of 45 deg. to 50 deg., the breath of the gun-deck upon an angulated iron-sided vessel is so much reduced as to be incapable of receiving and working her guns; the vessel would be washed over by a heavy sea; could have no rigging, on account of the deflection of the shot striking the angulated sides, and from the same cause would imperil those she was intended to defend."

The conical shields I proposed was an endeavour to remedy these faults. To apply deflective armour to an upright-sided ship, and to lessen the weight and thickness of iron usually required, I considered that while to the power of the gun there was no stop, to the thickness of the iron-plating there was a limit. That while it was an impossibility to render wholly impenetrable an upright iron side of a ship, the projecting the armour in the form of cones might permit a thickness of only 3 in. to be used, allowing a thickness of 10 or 12 in. for the weaker portions of the shield, the flatter parts, which Mr. Day so rightly considers would not deflect shot.

Already the 4½ inches of iron is found to be too weak, and a greater thickness is spoken of, rendering it absolutely necessary for some contrivance like the conical shields to be adopted, for it is admitted that much less resistance is required to be opposed by angulated plates in order to do the same or even more work than vertical ones.

The effect of the square-headed shot on the shields would, I expect, be very serious, but it would not be so damaging as it would be against a flat side of only 4½ in. thickness. It would rip up one and smash through the other.

Thanking Mr. Day for the notice he has taken of my deflective shields, and freely admitting that there is an Achilles heel to all such inventions, I assert that they are the only form of deflective armour that can be applied to sea-going vessels of war.

34, Kensington-square, I am, &c.,
20th October, 1862. C. J. Richardson.

MARINE ENGINE MAKERS.

Sir,—I observed in last week's edition of a contemporary, some remarks on the construction of marine engines in the Exhibition. The profound writer, after passing by the pickle and the toy trophies, with a look of disdain, proceeds to pass his judgment on the marine engines contained in the Western Annexe. After eulogising the work of all the great makers, and comparing the prices, he proceeds one by one to pull them to pieces. He advises Mr. Lloyd to offer £60 per horse-power for the best screw engines that can be had on the Clyde, Tyne, or Tees, and tells him that the London firms would be put to their "mettle" to produce work so good, which would be the means of giving all the trade to one spot, the very grievance Government has been trying to remedy by distributing their work fairly among the great manufacturers of the kingdom. He proceeds to find fault with the engines of Messrs. Maudslay, Sons, and Field, and gives great praise to those of Messrs. Penn. I have noticed that the said journal has always given great praise to all work manufactured by the latter firm, and has generally found some fault with the Messrs. Maudslay's productions. If the writer of that article should happen to be acquainted with any of Her Majesty's marine engineers, would he mind putting the following questions to them:—Which engines would they rather work or drive? Which engines require the most attention, and get heated soonest? Which engines consume the most oil and fuel, and soonest get out of repair? If he would ask these questions, he would find that Maudslay's engines require little or no attention when once started and the lubricators supplied. That the trunk engines of Messrs. Penn consume some gallons of oil per day more than those of Messrs. Maudslay, and a much larger amount of fuel. The trunks of Messrs. Penn's engines, if once allowed to run short of oil, in a few minutes will get so hot that the engineers have been known to pour water on them. The writer of the said article is perfectly correct in one sense in saying there is such a thing as too good work, for I do not think that the engines made by Messrs. Maudslay cost the Government much for repairs after the first payment. In speaking of the short connecting rods of the engines of Messrs. Humphrey, that able writer may have overlooked the fact that it is possible to make connecting rods a trifle too short. But he follows the path of most critics, finding fault where there is scarcely any fault to be found, and turning mole hills into mountains; if he could or would offer some advice that would tend to develop the subject which he is criticising, he would deserve and obtain the thanks of those particularly interested in the question. Hoping you will give this publicity, as I believe it to be the truth.

Yours truly,
Henry S. Jendrzejowski.

1, Union-street, London-road, Southwark, S.

Gossip.

It appears that the great company of the *Voitures de Paris* has been discussing with the police authorities the adoption of payment by distance instead of by the drive—and that a competition has been opened for what is called a "kilometrical reckoning apparatus," which while enabling the public to know exactly what is the driver's due, will also protect the cab proprietors from embezzlement on the part of their men. At a meeting of the shareholders held in August the director of the company announced that, notwithstanding many difficulties, a suitable apparatus was likely to be at last hit upon. No less than 148 instruments and several hundred projects had been sent in for approval. The adoption of the simplest and most practical of these would remove the great objection there now is to payment by distance—namely, the continual disputes it gives rise to between hirers and drivers. In this matter of cabs and cab-drivers, so important to the comfort and even to the safety of the public, the new London company may take some valuable hints from the one already long established in Paris, where it is certain that the carriages are generally better and the coachman more respectable than is the case in our own capital.

The following is an enumeration of the extensive network of railways in Italy, conceded to M. Bastoggi:—1. A grand line starting from Ancona, skirting the Adriatic and serving Pescara, Termoli, Foggia, Barietta, Bari, Brindisi, and Lecca, with a branch from Bari to Taranto, on the Ionian Sea, which together will form an extent of 740 kilometres, or 468 English miles. 2. A branch line from Foggia, passing from Ascoli, Causa, and Eboli, as far as Salerno, where it joins the line already constructed to Naples. Length about 181 kilometres, or 113 miles. 3. A branch line starting from Ceprano (where it meets the line already constructed from Rome to Naples) by Sora, Celano, Sulmona, and Popoli to Pescara, about 231 kilometres, or 145 miles. 4. A branch of 28 kilometres, or 17½ miles from Voghera to Pavia; and 5. Another branch of 167 kilometres, or 104 miles, from Pavia to Brescia, passing by Cremona. As to this branch, however, the Lombard and the Central of Italy Company claim a right of preference by reason of a previous concession. The extent of the lines to be constructed is 1,357 kilometres, or about 848 miles.

A new and large blast-furnace was blown in last week at the Consett Ironworks, Newcastle-on-Tyne. It was charged with 104 tons of coke, and 119 tons of minerals; and when it was tapped the yield was satisfactory beyond expectation. The size is nearly three times that of ordinary furnaces, and when in active operation the proprietors expect to derive 400 tons of metals per week from it.

A letter from Clermont (France), of the 13th inst., says:—"Two afternoons back a waterspout burst over the commune of Brignac, in the canton of Clermont-l'Hérault. In less than ten minutes the plain of Salamane was transformed into an extensive lake, the waters rising to a height of more than a metre. The carts occupied in the village had great difficulty in returning to the village. Happily no accident occurred. Several persons, surprised by the fall of this diluvian torrent, were compelled to take refuge in trees, and upon the walls which border the roads and private properties. Within the memory of man no such event had taken place in the neighbourhood, consequently all the inhabitants of the commune assembled after the storm, on the road from Brignac to Clermont, to discuss the effects of the waterspout, which may be considered as a really remarkable phenomenon."

It is frequently stated by those who wish to create panics, as an excuse for extravagant expenditure, that large works are being carried on secretly in the French dockyards. Nothing is more notorious, however, than that one government of Europe knows what all the other governments are doing. As a proof of this—Admiral Robinson, of the British navy, has just arrived at Toulon to examine the system employed in that port in the construction of iron-coated ships of war. The admiral has visited the principal dockyards in Europe for the same purpose.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

The Abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following Table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved, and combined with all the advantages of a division into classes. It should be understood that these abridgements are prepared exclusively for this Magazine from official copies supplied by the Government, and are therefore the property of the Proprietors of this Magazine. Other Papers are hereby warned not to produce them without an acknowledgement:—

FURNITURE AND APPAREL, including household utensils, time-keepers, jewellery, musical instruments, &c., 846, 864, 870, 881, 885, 889, 901, 905, 907, 912.
METALS, including apparatus for their manufacture, 848, 874, 910, 913, 919.
CHEMISTRY AND PHOTOGRAPHY, 878, 880.
ELECTRICAL APPARATUS none.
WARFARE, 872, 873, 895, 898.
LETTER-PRESS PRINTING, 915.
MISCELLANEOUS, 847, 854, 855, 857, 859, 861, 862, 871, 877, 883, 890, 892, 894, 896, 903, 917, 920, 921, 922, 926.

846. T. G. GREENSTREET. *Improvements in window sashes.* Dated March 27, 1862.

Here the inventor forms each side of the framework of two pieces or strips of wood or other material, one of which is fixed to the top and bottom sides of the sash at each side thereof, and the two other pieces are loosely connected to the fixed pieces, each by a screw, which serves as a pivot on which to turn the sash inside out for cleaning or repairs. The aforesaid loose pieces fit into the window frame in which the sashes slide, and are connected by lines to sash weights. In order to keep the sash air-tight, he forms a groove in the edge of the loose pieces aforesaid, and also in the edge of each of the fixed side pieces of the sash. He also forms a groove in the bottom edge of the bottom rail of the bottom sash, into which he places a strip of vulcanized india-rubber, long enough without stretching to reach up to the top of the sash, in the grooves of which it fits at each side, as also in the grooves in the loose pieces before named. He also fixes a piece of metal to each end of the india-rubber, by pulling which the india-rubber will be stretched and withdrawn from the grooves in the loose pieces aforesaid, and may be held in this position by inserting the aforesaid pieces of metal into holes formed in the top rail of the bottom sash and the bottom rail of the top sash. The window can then be turned inside out on its pivots. He also inserts and fixes a strip of vulcanized india-rubber in a groove formed in the top or bottom sash for the purpose of excluding the air or dust. *Patent abandoned.*

847. F. TOLHAUSEN. *New or improved cigar tubes or apparatus for holding and smoking cigars and cigarettes.* Dated March 27, 1852.

This invention is not described apart from the drawings. *Patent completed.*

848. R. EDWARDS. *Improvements in machinery and apparatus for pulverizing, stamping, and washing mineral, animal, and vegetable substances.* Dated March 27, 1862.

This relates, primarily, to the application of a circular inclined surface for raising the hammers, stampers or beetles; and secondly, to the general arrangement of the parts of machines used for these purposes, as hereinafter described. For grinding quartz, emery, and other ores, the patentee uses an annular trough to receive the material to be operated upon, and the stampers, which are arranged in a circle, and are mounted on levers radiating towards the centre; these are cranked downwards, and dip in a basin, within which the levers and hammers are mounted on centre point bearings, which basin is filled with oil to lubricate the parts. A vertical shaft is disposed in the centre, carrying the circular incline, placed immediately above the short ends of the levers, which are furnished with contact points or friction rollers. This shaft is rotated by wheel gearing, and as it carries round the incline, it acts on the whole of the levers, so as to raise them gradually and continuously, and allowing them to drop one at a time on the matters to be operated on; or there may be two, three, or more inclines in the circle, and two, three, or more stampers allowed to drop at same time. *Patent completed.*

849. W. F. HENSON and H. H. HENSON. *Improvements in wicks for candles and lamps.* Dated March 27, 1862.

This consists in the manufacture, use, and application of paper wicks, or wicks composed of paper, papier maché, and other suitable materials combined therewith for candles and lamps. *Patent abandoned.*

850. J. LOCK. *Improvements in apparatus for raising or elevating straw and crops on to stacks.* Dated March 27, 1862.

Here the inventor uses a framework or carriage, by preference mounted on wheels, and fitted with shafts, so that it may readily be moved from place to place by a horse. This carriage has a long and narrow rectangular frame mounted on it, the frame being connected at one end with an axis having its bearings on the carriage, so that by turning the frame about its axis its further end may be raised to any desired height from the ground, and there is suitable apparatus to retain it in any desired position. This frame carries the bearings of a series of rollers or drums, placed parallel the one to the other, and at a short distance apart. The rollers or drums are furnished with projections or teeth, and are all caused to revolve by arms and rods or other instruments connecting them with an axis which is driven by a steam engine or other means. When the apparatus is at work, the outer end of the roller or drum frame is raised to the required extent, according to the height of the stack, and the straw or crop being presented to the lowest roller or drum of the series is taken by the projections or teeth thereon, and carried forward to the next roller or drum, which then takes it, and in this way the straw or crop is carried forward and elevated until delivered on to the stack. *Patent abandoned.*

851. E. H. C. MONCKTON. *Improvements in the manufacture of effervescing liquids.* Dated March 27, 1862.

This consists in combining with effervescing drinks, spirits, brandy, wines, liqueurs, or other flavourings. *Patent abandoned.*

852. J. L. H. C. COUNTESS DE VERNEDE DE CORNEILLAN. *Improvements in treating open cocoons of silkworms, and in converting the waste resulting therefrom into paper.* Dated March 27, 1862.

This invention consists in a particular treatment of cocoons naturally open, or with an orifice made by the chrysalis, and in the cottonizing and transforming into paper the waste resulting therefrom. The first part of the invention relates to the decortication and the drawing out of raw silk from the cocoons naturally open, of the *Bombix* and of all other species, with an orifice opened by the chrysalis passing into the moth or butterfly state. To decorticate the cocoons of the "*Cynthia de l'ailanthe,*" the inventress uses a small instrument with movable spatulas; the cocoons are then plunged into a boiling soapy solution, where they remain from fifteen to twenty minutes, then into boiling water to which a volatile alkali has been added; the water is stirred, the vessel containing the liquid and other matters is closed, and after the expiration of a few minutes disaggregation is perfect, and the drawing off may be effected. The cocoons are removed from the vessel and are placed in a shallow sieve with large meshes immersed in a vessel full of boiling water. The sieve is raised completely out of the water, and the cocoons are allowed to drain, and she then winds off from the cocoons while damp and quite out of the water. To draw easily several threads at one time, the sieve may be divided into compartments to prevent the mixing of the threads. She winds off with equal facility from cocoons from which the chrysalis has escaped, the weight of the water which fills them being equivalent to that of the chrysalis. The disaggregation of the Ricin cocoons ("*Bombix Arrindia du Ricin*") is effected in a few minutes; they need only be decorticated after the boiling. One boiling water, or one boiling water slightly soapy is sufficient. We cannot give space to the whole of the details of the invention. *Patent completed.*

853. R. A. BROOMAN. *Improvements in machinery for preparing, combing, and dressing vegetable fibres.* (A communication.) Dated March 27, 1862.

This invention consists, first, in the employment in machinery for preparing, combing, and dressing vegetable fibres, of endless chains passed and extended round drums or cylinders. The transverse links or bars of the chains are plain and serrated on their surface, so that they act as combs and beaters or scrapers; one serrated edge and two plain are preferred alternately. The chains are placed in pairs, one above another, and the drums or cylinders are supported in strong bearings, and have motion communicated to them from any prime mover. The invention consists, second, in the employment of an endless chain for conveying the material to be operated upon to the machine. It is extended round two shafts, and has motion imparted to it through a pinion on one of the drum shafts through another toothed wheel and a pulley and strap on one of the shafts round which the endless chain passes. A gripper connected to this chain holds the material while the beaters or scrapers and combs act upon and dress the fibres. The machine is constructed in such manner that the axles may be prolonged, or the frame be brought out at the side, so as to enable the gripper to draw out the combed fibres at the side of the machine. Instead of two sets of endless beaters or scrapers and combs, in some cases one set only is used. *Patent abandoned.*

854. R. DE BARY. *Improvements in machinery for the manufacture of cigars.* (A communication.) Dated March 27, 1862.

This invention consists in certain improvements on a former invention, for which letters patent were granted to the present patentee, 1st November, 1859, No. 2,493. The mechanism then described for causing the rise and fall of the knife is here replaced by *two eccentrics*. The tobacco, on leaving the box or case by which it is fed to the machine, is guided to the knife, cut, compressed, and carried on to a band stretched over a curved plate or sector, free to oscillate about a fixed point. There is a space or pocket formed in the band into which the cut tobacco falls, and wherein it is pressed by a plunger; a roller advances, folds the band over the tobacco, and the curved plate moving at the same time, carries on the cigar thus partially manufactured with it. To regulate the thickness of the cigar, a roller is placed above the band, which consolidates the tobacco as it passes under it. The envelopes or outer skins for the cigars are led up by an endless band which, through two guides, the lower of which revolves, causes the envelope to be wound round the cigar. Motion is communicated to the endless band by a drum or cylinder ronnd which it is passed. There is a toothed wheel on the drum shaft in connection with a ratchet, having a curved arm or branch proceeding from it bearing against a small roller beneath, by the action of which the motion of the drum and band may be regulated or stopped. The toothed wheel before mentioned, through a cranked and connecting rod, communicates motion to the curved plate, which is in unison with that communicated by the drum to the endless band. As the curved plate oscillates it carries the cigars down with it, and deposits them into compartments formed in an endless chain into boxes, or into any other convenient receptacle. *Patent completed.*

855. J. EASTERBROOK and J. H. ALLCARD. *Improvements in vices.* Dated March 27, 1862.

The objects of this invention are, first, to render the bench vice more effectual in its operation by causing the movable jaw to move, as hereafter described, in a straight line parallel to the direction of the action of the screw, instead of in a circular arc, as heretofore; second, to render vices more effectual for gripping taper articles. The improvements are effected in combination with the ordinary vice box and screw, with either solid or brazed threads in brass, copper, wrought iron, annealed malleable cast iron, or any other metal or combination of metals that may be found most convenient and useful, or the thread may be cut in the fixed jaw. The movable jaw in the parallel vice is steadied and guided in its movements by a metal bar working and bearing upon a suitable plate fixed below the screw and box at any suitable distance. The plate for fixing the vice to the bench bears, by preference, upon the bench or under the bench, assisted in some cases by a leg reaching to the floor, welded, screwed, or otherwise fixed to the slide plate, or to either of the jaws whenever found necessary for the proper securing and supporting of the vice. In some cases the inventors make the parallel vice self-adjusting for gripping cotters or other taper work by means of a swivel or joint formed in either one of the jaws. The swivelling jaw is compensated by spherical washers placed upon the screw or box in order to secure at all times a proper bearing for the screw upon the jaws. The movable jaw may be connected to the screw in many ways, in order to cause the said screw to carry the jaw with it in all its motions. *Patent abandoned.*

856. W. E. GEDGE. *Improvements in apparatus for extinguishing fire.* (A communication.) Dated March 27, 1862.

This invention is not described apart from the drawings. *Patent completed.*

857. S. A. EMERY. *Improvements in the manufacture of soap.* Dated March 27, 1862.

This consists in combining with the saponaceous materials usually used in the manufacture of soap, woody fibre reduced to a finely-divided or pulverized state. *Patent abandoned.*

858. J. H. JOHNSON. *Improvements in thrashing machines.* (A communication.) Dated March 27, 1862.

This consists, essentially, first, in the use of two separate and distinct beaters or drums, placed side by side, parallel to each other, and each supplied from a separate feeding board or table of its own. The extra table for the second drum, or set of beaters, is made to fold down when the machine is being transported, against the end thereof, and held in that position by suitable hooks or catches, so as to occupy less space; second, in the use of an elevator for raising the winnowed grain up to the level of the sack's mouth, thus obviating the necessity of having a high machine; third, in applying a series of hooks or serrated plates to the surface of the shaker, for preventing the straw from returning and choking the beaters. *Patent abandoned.*

859. W. F. SMITH and A. COVENTRY. *Improvements in and applicable to lathes and machines for turning and for cutting screws.* Dated March 27, 1862.

This invention is not described apart from the drawings. *Patent completed.*

860. G. H. BIRKBECK. *Improvements in the means of producing imitation mosaics.* (A communication.) Dated March 27, 1862.

Here the model of the design is first executed on paper, and coloured, to give an idea of the general effect ultimately required. This model design is cut into sections of the various parts of the design. These several sections, composing the picture or other work of art, are then placed separately on plates or surfaces of baked or unbaked earthenware, metal, or other substance suitable for enamelling upon, which is then cut or shaped to the exact contour or shape of the particular part of the design under treatment. When all the parts are thus arranged they are placed together to ascertain if they fit correctly, so as to represent the original design. The various parts are then covered with enamel, either separately or combined, the enamel being so applied to each part as to produce, when "fired" or baked, the various colours required in the complete design. When baked the parts are combined and cemented or secured together in any convenient way. *Patent completed.*

861. G. ALLCROFT. *Improvements in pressure and vacuum-gauges.* Dated March 28, 1862.

An important feature in this invention is the substitution, in place of a metal spring, of a piece of vulcanized india-rubber, sufficiently thick to resist great pressure, or variations of pressure, acting in combination with certain mechanism, the details of which we cannot here devote space to. *Patent abandoned.*

862. J. JONES. *Improvements in apparatus for raising and forcing liquids.* Dated March 28, 1862.

This consists in raising and forcing liquids by a piston and cylinder, which is closed at the top, and provided with a stuffing box for the passage of the piston rod, which is acted on by a screw or other equivalent, for regulating the position of the piston in the cylinder. The lower end of the cylinder is either entirely open, or furnished with a lid, having an opening for the pipe through which the liquid to be raised enters the cylinder; the piston is brought down in the cylinder till it bears upon the liquid, which is then forced up a pipe in communication with the cylinder, and elevated to the required level by the force of the ascending liquid, or by the action of the piston. The piston is provided with valves to allow the liquid in the upper part of the cylinder to pass when the piston is being raised. *Patent abandoned.*

863. W. A. ASHE. *An improved mode of apparatus for driving the propelling shaft of ships or vessels.* (A communication.) Dated March 28, 1862.

This consists in a method of imparting a rotary motion to the shaft of a screw propeller or other shaft without the use of a crank, connecting rod, driving band, or toothed gearing. *Patent completed.*

864. W. B. NATION. *Improvements in manufacturing boxes or cases, and in the machinery or apparatus employed therein.* Dated March 28, 1862.

Here the patentee uses a block or mandril of wood having its transverse section of the same shape as the external casing of the boxes or cases required to be made. This block is covered with one or more layers of paper, strengthened by gelatine, mixed in about equal proportions with carbonate or salts of lime, aluminous, or silicious substances; or he uses silicates of potash or other alkalies, without the aid of gelatine, which substances are coloured in any way. The covered blocks are now passed through a drying chamber by endless bands or chains, and when the material is sufficiently dried, it is removed from the wood and cut into the proper lengths by a circular saw, which operation completes the exterior of the box or case. For forming the interior of the box he uses another block, and covers it with one or more layers of paper, strengthened as before described. The block is of such dimensions that, when the material is divided longitudinally into two parts, each of the parts may pass in the inside of the external casing, and when the internal part has end pieces affixed to it, the box is complete; it can be ornamented in any desired way. *Patent completed.*

865. R. A. OWEN. *Improvements in feathering and varying the pitch of screw propellers for steam ships.* Dated March 28, 1862.

The patentee claims, first, the use of rods passing from the

propeller through the stern pipe, stuffing box, or gland, and revolving with the propeller shaft, for communicating motion from the engine department to the feathering and locking gear; second, the use of the cylinder working fore and aft inside the boss of the propeller, and on the propeller shaft, and the rack and pinion, which communicate the motion from the cylinder to the blades; third, the locking gear for fastening the blades in their several positions, and the use of the split nuts or bushes for securing the blades in their places without weakening them, by key-ways or slots; and, also, the collar on the blade spindle with the recesses, or holes for the lock to ent r; fourth, the use of the collar or flange on the propeller shaft when used to insert screws for the working backwards and forwards of rods used for feathering or locking the blades; lastly, using the propeller boss cut in halves at right angles to the propeller shaft, for the purpose of inserting the blades. *Patent completed.*

866. E. T. MONALHIER. *An improved ventilator.* Dated March 28, 1862.

This ventilator is essentially composed of two hollow and concentric cylinders of sheet iron or zinc. These two cylinders are in their entire length separated from each other by a small circular space, which leaves a free passage for the air. The inner cylinder represents but the continuation of the chimney-flue; it terminates at about the middle of the length of the exterior cylinder in which it is contained. This latter is completely closed at the extremity which corresponds with the lower extremity of the inner cylinder, and contrary to which it is immovable; it will pivot with the greatest facility around its congener when the slightest rotary motion is given to it. Further, it presents on one of its faces a large open throat, and upon its opposite face a species of wing, which forces this throat always opposite the wind. *Patent completed.*

867. A. LUCETTI. *Improvements in apparatus for expressing the juice from pulpy fruit.* Dated March 28, 1862.

This consists in the use of a pair of jaws, the lower hinged to the upper, which works on a fixed centre, and is acted on by a lever handle which, when depressed, causes it to press the fruit upon the lower jaw. The inner surfaces of these jaws may be made more or less roughened, grooved, or corrugated, and the expressed juice is received into an inclined spout which directs it into any convenient receptacle. A spring is applied for the purpose of opening the jaws on the release of the pressing handle. The entire apparatus is proposed to be mounted upon a vertical standard, which is fixed into a table or other convenient support. *Patent abandoned.*

868. J. H. JOHNSON. *Improvements in chaff-cutters.* (A communication.) Dated March 28, 1862.

The variation in the length of the chaff is, according to this invention, effected by having a movable pinion fitted on to the end of the driving shaft, which is changed for a larger or smaller one, according to the size of chaff required. This pinion gears into an intermediate wheel, which drives a third spur-wheel. On the axis of this last-named wheel is a bevel pinion, which drives a transverse shaft, from which the motion is transmitted to the two feed rollers. The upper roller is capable of adjustment to or from the surface of the lower one, and both rollers are driven by bevel pinions carried by a vertical shaft, which derives its motion from the transverse shaft. In order to allow of the adjustment of the upper roller, the pinion which drives it is capable of sliding along the vertical shaft, which may be made of a square section. With a view to prevent the choking of the machine, and to regulate the supply of straw, it is proposed to use a cover or hood placed over the upper roller. *Patent abandoned.*

869. E. SMITH. *Improvements in wet gas-meters.* Dated March 28, 1862.

This invention is not described apart from the drawings. *Patent completed.*

870. R. LUBLINSKI. *An improved method of jointing crutch hooks, or umbrellas, or walking canes.* Dated March 28, 1862.

The patentee makes a plug of hard wood or metal, which he inserts in the hollow at the top of the cane, which plug, being first made quite fast inside the cane, a portion thereof protrudes upwards, so as to fit in a receptacle made in the crutch hook or handle to receive the top of such plug, while an iron or steel peg shall pass horizontally through a part of the hook or handle from the back, and also through the portion of the plug protruding upwards, thereby securely fastening the hook or handle to the cane or stick. He fills in or covers over the hole made in the back portion of the handle for the passage of the metal peg with a piece of the same cane, or any other material as fancy may dictate. He grooves out a portion of the top of the cane or stick, which will allow the hook or handle to drop or fit in, while the sides of the groove will grip or clutch the hook or handle. *Patent completed.*

871. R. KAY. *Certain improvements in printing calicoes and other surfaces, and in apparatus connected therewith.* Dated March 29, 1862.

This consists of an internal cylinder, having an external covering of india-rubber, or other elastic substance, so as to form a cavity or chamber between the two, which cavity is to be supplied by tubes with water or other liquid from a cistern, and the pressure duly regulated by valves; the surface of the india-rubber may either be corrugated or covered with woollen or other fabric. By the rise of the confined water for the color cylinder or sieve, a more yielding or compensating bed is formed at the point of contact with the printing or type cylinder. *Patent abandoned.*

872. J. BOUCHER. *Improvements in rifle ordnance and fire-arms, and in the projectiles to be used therewith.* Dated March 29, 1862.

Here the patentee makes the grooves extremely shallow and concave, the edges merging gradually into the original cylinder of the bore, so that there are no sharp angles whatever at the sides of the grooves. He also makes the grooves shallower at the breech than they are at the muzzle, so that there is no windage. The projectiles are formed polyganally, or many-sided, not so as to fit into the grooves, but having a greater number of sides than the number of lands and grooves in the barrel, the number of such sides being so proportioned to the number of lands and grooves that the projectile cannot be placed incorrectly in the barrel while loading, even in the dark. *Patent completed.*

873. Y. PARFREY. *Improvements in breech-loading fire-arms.* Dated March 29, 1862.

This invention is not described apart from the drawings. *Patent abandoned.*

874. W. CLARKE. *Improvements in apparatus for casting.* Dated March 29, 1862.

Provisional protection has not been granted for this invention.

875. J. MORRIS. *A new or improved machine for breaking up or cultivating land.* Dated March 29, 1862.

This consists of a machine so constructed that when in motion a series of forks or prongs, having an advancing horizontal motion, are made to enter the land to the depth of several inches, and afterwards rise therefrom, the said forks or prongs performing a nearly circular motion in a vertical plane. *Patent completed.*

876. C. H. TOWNSEND, J. YOUNG and J. HAWKINS. *Removing and preventing incrustation in steam-boilers.* Dated March 29, 1862.

This consists in the use of valonia, sumach, and potash. *Patent abandoned.*

877. W. SMITH. *An improved fire-engine.* Dated March 29, 1862.

Provisional protection has not been granted for this invention.

878. W. GLASS. *Improvements in the treatment of sulphuret of antimony, and in obtaining products therefrom.* Dated March 29, 1862.

Here the inventor takes any of the well-known black sulphurets of antimony, called antimony ores, or the refined or called crude antimony, and places it, with or without additional sulphur, in a crucible or other convenient covered or close vessel, in a furnace, and heats it or them to redness in a melted or fluid state, and forces upon or into it or them atmospheric air or oxygen gas, provision being made in the crucible or other vessel for the ingress of air or oxygen, and for the egress of the vaporous products of combustion, viz.:—oxide of antimony and sulphurous acid, which are conducted into tubes, flues, or chambers, where the oxide of antimony is condensed as a fine white powder, and the sulphurous acid may be used as such, or it is oxidated or converted into sulphuric acid by oxygen and steam, as is usually practised in vitrol works. *Patent abandoned.*

879. T. COLE. *Improvements in the manufacture of figured ribbons and other textile fabrics.* Dated March 29, 1862.

This invention consists in substituting for the jacquard machine a machine formed of a horizontal barrel or cylinder, with wire studs attached. These studs, in revolving, press on iron bolts which come in contact with hooked rods, and press the same to the griff, and the griff raises the rods to form the figure on the ribbon. Sometimes the inventor uses slats with wire studs, attached or not to the cylinder, and instead of a cylinder a piece of wood of square or octagon shape may be used. *Patent completed.*

880. W. PATERSON. *Improvements in the manufacture of iodine.* Dated March 29, 1862.

The patentee claims the system or mode of manufacturing iodine, in which the residual still liquor is utilized and applied to the keep leys for neutralizing and decomposing, or partly so, the salts contained therein, and thereby economize the quantity of sulphuric acid which would otherwise be required. Also the application of the precipitate of the compound solution for the purpose of saturating the free acid contained in the residual still of the iodine manufacture, as described. *Patent completed.*

881. R. SMITH. *Improvements in roller blind apparatus.* Dated March 29, 1862.

This consists in suspending a weighted pulley in the lower double or bight of the cords of such apparatus, which pulley may be confined in a vertical slide to guide it, or it may hang loose. The cord or chain by which the weight is suspended is either passed directly down and through the sole of the window frame, or diverted horizontally by passing under a pulley, thence through the side lining of the window, and over another pulley, and from thence the weight depends and applies the necessary force to impart the tension to the cord desired. A weight is suspended at all times, gives to any contraction of the cord, and also takes up any slack due to expansion, and so keeps a uniform tension on the cord. *Patent abandoned.*

882. J. BAKER. *Improved alimentary preparations.* Dated March 29, 1862.

Here, in preparing a concentrated preparation of beef tea, the inventor reduces the beef by stewing in the ordinary way, and adds to 112 lbs. of the beef about 2 lbs. of Jamaica sarsaparilla; he then strains the beef tea from the fibre, and reduces it again by boiling or stewing until there remains about one-sixth part of the original weight. It is then put in close cases in which it sets. According to the second part of the invention a vegetable extract is prepared from carrageen moss. *Patent abandoned.*

883. E. B. HART. *Improved machinery for cutting cork so as to render the same suitable for stuffing purposes.* (A communication). Dated March 29, 1862.

The patentee claims, first, the knife box or shield described, which retains firmly each knife placed in it, permitting only the point to protrude and operate; second, the application of a circular knife-edged saw, which, being a combination of knife and saw, produces a smooth uniform shaving, as described; third, a self-supplying feeding box, which, by a pull of a ratchet wheel coming in contact with the bar, produces the motion of the grooved cylinders whereby the cork is fed progressively to the action of the knives and saw, as described; fourth, a method of divisional pressure, produced by four or more independent fingers, in connection with india-rubber springs, &c., as described; to each finger is given an independent, and yet to the whole surface there is given a united and even pressure, regardless of any irregularity of the thickness of the cork; and, lastly, he claims the material or fibre produced by the machine in the manner aforesaid, and its application to various useful purposes as specified. *Patent completed.*

884. J. PLATT AND W. RICHARDSON. *Improvements in carding engines.* Dated March 29, 1862.

The patentee claims the use of a second crank or cranks and balancing apparatus as described. *Patent completed.*

885. W. E. NEWTON. *An improved mode of applying acoustic apparatus in churches and other buildings and apartments.* (A communication). Dated March 29, 1852.

This consists of a funnel-shaped receiver, of an elliptical form at its mouth, which fits to an opening in the top of the pulpit and collects the sound. The elliptical funnel-shaped receiver gradually assumes a circular form towards the bottom, where it terminates in a circular throat, from which a pipe runs under the floor to any convenient point, where it is led upwards through the floor to connect with a taper flexible tube, at the end of which is an ear piece to be placed in the ear of the person requiring it to conduct the sound thereto. *Patent abandoned.*

886. J. CLINTOW. *Improvements in flutes.* Dated March 31, 1862.

This consists in making the first, or lower C sharp hole, nearly as large as the diameter of the cylinder; the other holes, up to the twelth, or C natural hole, are gradually reduced in size. *Patent completed.*

887. M. A. F. MENNONS. *The manufacture of glucose, or fermentable sugar, from a vegetable product not hitherto used for that purpose.* (A communication.) Dated March 31, 1862.

This consists, first, in the application of carol beans, or fruit of the carol tree (*ceratonia silicia*), to the production of a species of glucose, or fermentable sugar, adapted to a variety of manufacturing purposes; second, in a certain process, by the aid of which this substance is extracted from the raw material thus applied. *Patent abandoned.*

888. J. JORDAN. *Improvements in the construction of armour-plated vessels or other like structures.* Dated March 31, 1862.

Here the armour plates are composed of a mixture of pig iron and malleable iron, melted together in such proportions as may be found advantageous, and afterwards annealed, and they may be case-hardened. The holes for the bolts may be cast or bored in or through the plates, or nuts of wrought iron may be bedded in the mould, and the metal cast round them; and in this case it is preferred not to form the nuts so deep as the thickness of the plates, so that no holes shall be required through the plates; or the bolts may be screwed into the plate any required distance, but so as not to actually perforate the plates on the outside. The invention further consists in the use of suitable cement placed between the joints of armour plates, and between the armour plates and wood backing, and also between and behind the wood backing. *Patent abandoned.*

889. R. YOUNG. *Improvements in apparatus for cleaning, separating, washing, and drying grain.* Dated March 31, 1862.

This invention is not described apart from the drawings. *Patent completed.*

890. W. FRANKENSTEIN. *The cutting of all kinds of corks, both pointed, conical and cylindrical.* (A communication). Dated March 31, 1862.

This consists in the construction of a machine which cuts corks by hollow, cylindrical, or conical knives being made to pass perpendicularly through cork which has been cut into strips, the strips being as long as they can. The length of the cut corks will correspond with the depth of the strips, and the thickness of the cut corks with the diameter of the hollow knives. An endless band passing over a wheel sets the machine in motion. *Patent abandoned.*

891. W. TYLER. *A new or improved mixture or composition for feeding dogs and other animals and poultry.* Dated March 31, 1862.

This composition consists, essentially, of dried or liquid blood, combined with vegetable or farinaceous matter, either with or without the addition of ground bones, as described. *Patent completed.*

892. W. H. HOOK. *Improvements in folding envelopes and paper, and in machinery or apparatus employed therein.* Dated March 31, 1862.

The patentee uses a skeleton frame of thin metal, or other material, of the required size and shape, and covers the edges thereof, or the sides and edges, with linen, silk, leather, or other absorbent material. To the said skeleton frame he supplies water or other liquid, so that its edges shall be moistened, and then presses the frame on the paper, or presses the paper on the frame, by which operations the absorbed material covering the edges of the frame will moisten or damp the paper in lines corresponding with the edges of the frame, and thereby enable the operation of folding to be greatly facilitated. The pressure is obtained by an ordinary copying or embossing press, lever, or other contrivance, and constant supply of water or other liquid is supplied in any convenient way. *Patent completed.*

893. J. P. WOODBURY. *An improvement in arming war vessels.* (A communication.) Dated March 31, 1862.

This invention relates to a method of arming war vessels, both as regards their means of attack and detence, and is designed, among other things, to enable a vessel to attack and overpower the iron-clad war steamers which are now being built by the naval powers of the world, and at the same time enable them to be constructed and employed at a reasonable cost. The manner in which the patentee proposes to accomplish this object may be stated in general terms to consist, first, in providing a hull of good model for speed, with a shallow draught of water, and of a capacity to carry coals and machinery sufficient to excel in speed any vessel designed to be attacked. Secondly, in providing means for sinking it to the deck by water ballast when going into action, so as to expose the smallest possible part of the ship to an enemy's fire, which part only would require to be plated with thick iron to protect it from shot. Thirdly, in making the deck convex or circular, both longitudinally and transversely, so that, when the vessel is submerged to a fighting trim, the sides of the deck will be

below water, and the surface exposed will be presented to an enemy's shot at a low angle, and also that the centre of the deck will be sufficiently above water to enable the vessel to be worked in a sea way. Fourthly, in forming in the middle of the deck a low oblong trunk projecting upward a short distance from the deck, and plated so as to be secure from shot, through the sides of which small holes are made for the purpose of observation externally, and for the purpose of defending the deck by musketry, by ejecting hot water, or any other means. These holes are flared upon the inside to permit a wider range of observation and attack after the manner of a loop-hole for musketry in fortification. The top of the trunk is provided with several large openings, thoroughly secured by shot-proof gratings, through one of which the smoke from the boiler emerges, and through the others the hold is ventilated by fan-blowers or otherwise. The steering wheel is also placed within it, and from within it all the movements of the vessel are directed. Fifthly, for the purposes of attack, the vessel is provided with, say, three or more breech-loading cannon of large calibre, which are mounted, one at the bow ranging fore and aft, and one on either side ranging athwart ship, the muzzles of which extend through the sides of the hull at a considerable distance (say ten feet more or less) under water, and are provided with many accessory devices to enable the guns to be worked under such conditions. They are designated to carry a large oblong hollow projectile or shell, containing a great bursting charge, which is to be thrown into the hull of the vessel to be attacked, and there exploded by a fuse. The guns are made to work in stuffing boxes in the side of the hull, and have a movement only in a longitudinal direction, and are not designed to be armed, as they are intended to be used only when they are near the object to be assailed. *Patent completed.*

894. W. B. Lord and F. H. Gilbert. *An improved hame slip for suddenly releasing horses and other cattle from their harness, also applicable for releasing heavy bodies or weights.* Dated March 31, 1862.

This hame slip interposes between the hame and trace, and is composed of a piece of metal, having two deep open slots cut in the broad or circular portion thereof. These slots or cuts divide the circular part of the metal into three parts, which may be termed cheeks. A pin-hole is made in the inner and centre pieces or cheeks, and in the outer a key-hole shaped slot. A spindle passes through these holes and works longitudinally therein freely. A groove is cut along the bottom of the spindle, into which a screw takes, the screw being passed through the lower part of the centre cheek, thus preventing the spindle turning entirely round, when it is withdrawn to allow the trace to drop from between the inner and centre cheeks of the slip. Hinged with or into one end of the spindle is a T or other shaped piece serving to pull out the spindle as far as the stop, or push it back in its place, and in conjunction with the slot secure it in position. *Patent completed.*

895. W. B. Lord and F. H. Gilbert. *Improvements in loading fire-arms.* Dated March 31, 1862.

Here the inventors propose to use an apparatus which shall entirely prevent coagulation of the powder on the inside of the barrel. Each Enfield rifle has a screw threaded on the point of the ramrod; they screw on to this point a small piece of metal with open sides, and to this piece hangs a cylinder of capacity to hold the exact charge of powder required to a load. At the bottom of the cylinder, which is partly open, is a mushroom valve, connected by a pin, which passes through the bottom of the cylinder to a deeply-grooved projecting head or ball. The action is as follows: the piece being screwed on to the end of the ramrod, the cylinder is placed on the barrel, where it hangs vertically, the ramrod being in a horizontal position; the charge of powder is then poured into the cylinder, the ramrod raised vertically passes the cylinder down to the breech, the head or ball on touching the bottom pushes up the mushroom valve, and the powder at once escapes through the grooves of the head or ball into the breech. The apparatus is then retired and the loading completed in the usual manner. *Patent abandoned.*

896. R. Burley. *An improved material for forming or lining the bearing of axles and shafts and other rubbing parts of machinery.* Dated March 31, 1862.

Here the patentee employs an alloy, consisting of iron, copper, tin, and zinc, combined with a small quantity of sulphur, and sometimes also of arsenic. *Patent completed.*

897. C. R. Ransome. *Improvements in thrashing and other machinery where corn or grain is required to be raised from one level to another.* Dated March 31, 1862.

This consists essentially in the employment of a revolving wheel or surface, on the periphery, or at a distance from the central axis, of which are applied propellers, buckets, or paddle boards, which work within a chamber of cylindrical form. *Patent completed.*

898. R. Nightingale. *Improvements in markers, butts, or mantelets.* Dated March 31, 1862.

Here the inventor constructs a marker's butt or mantelet, enclosed on all sides, and he makes all parts sufficiently bullet-proof to prevent accident to the markers, whether by the direct action of bullets or portions of bullets, or by their rebound, or by their being deflected by the butt or mantelet, or from any substance struck by a bullet; and in order to enable the markers to ascertain the position where any balls may strike a target, he applies at the upper part of a marker's butt or mantelet a bullet-proof camera, so arranged that it may throw an image of the target on to a table or surface below, on which is placed properly ruled or prepared paper, corresponding with the divided surface of the target, so that the mark made by each bullet in striking the target will be imaged in its precise position on the ruled or divided paper, and be then marked or indicated by the marker with ink or other material, together with the number of shot; and in order to obtain a full record of all the shots, the marker may also register or mark in the margin of the paper all shots which miss the target, together with their numbers, or the order in which such misses have occurred. Inclined or bent passages or tubes are applied, which prevent the passage of light, but admit air and sound freely. *Patent abandoned.*

899. L. B. Schmolle. *Improvements in the construction of crinolines or steel skirts.* Dated March 31, 1862.

The patentee claims constructing steel skirts with series of junctions arranged in lines in the steel strips that permit of bending in a horizontal direction, as described. *Patent completed.*

900. J. Harding. *Improvements in the application of the waste heat arising from coke ovens for heating air for blast furnaces, also for calcining iron, stone, and other minerals, and for heating and smelting iron.* Dated March 31, 1862.

The inventor causes the mouths of a group of coke ovens to open into a flue, in place of into the atmosphere, such flue leading direct either to an ordinary calcining furnace or chamber, or to a smelting furnace or air-heater, according to the purpose for which the spare heat is intended. *Patent abandoned.*

901. J. M. Clements. *Certain improvements in sewing machines for performing the various kinds of work necessary in stitching, button and eyelet-hole working, embroidery, and sewing generally.* Dated March 31, 1862.

In giving effect to this invention the inventor fixes one or more axles, cranked or otherwise, or their equivalents, such as cams, on a suitable bed or cast frame, deriving their motion from a friction pulley or other means at the back of the machine, and which may be worked with a treadle or otherwise as required, the eccentric end of the crank or cranks operating on and regulating the action of the shuttle and levers, elevating the shuttle during the time of its passing through the loops, and bringing it back through an irregular curve below for repeating its former motion. By this arrangement the shuttle is removed while the levers are forming and the hooks taking up the several loops required previous to the shuttle again passing through them. The nose or sharp end of the shuttle will be always kept in one direction by means of a slotted lever working vertically or horizontally. Or, as a modification of this arrangement, and to avoid the necessity of having the two loops round the shuttle at one time, the shuttle may be made sharp pointed at each end, so that in its traversing motion it shall pass through each loop individually, one in its forward motion and the other in its return motion, making the complete stitch, thereby decreasing by one half the slack silk or thread to be pulled tight at the completion of each stitch. This arrangement enables the patentee to form each loop with but one hook instead of two, the using of only one hook enabling the operator to work much smaller button or other holes than if two were used. *Patent completed,*

902. J. H. Johnson. *Improvements in rotatory engines.* (A communication.) Dated March 31, 1862.

This invention consists in the employment of a pair of disc wheels, having a number of steam ports cast therein, each disc being fixed on a separate shaft of its own. In place of the two shafts being in the same axial line with each other, they are placed at an angle, so that one edge of the discs will be nearer together than the opposite edge. The steam ports or passages pass through the discs, and the corresponding ones in the inner faces of the discs are connected by expansible bags or tubes of vulcanized india-rubber, or other suitable material. A valve is so arranged as to admit the steam into each port successively, as the discs revolve, the steam entering that port and bag or tube which is situate at the point where the edges of the discs are nearest together. As the steam expands this tube, it tends to rotate the discs, and bring the next succeeding port under the valve, which then receives steam in its turn, and so on, the exhaust taking place through the opposite disc, and at a point where the expansion of the tube is no longer of service. Motion is transmitted from these discs by having spur teeth cast thereon, gearing into corresponding pinions on a second motion shaft. The bearings which support the shafts of the two disc wheels are made adjustable on their tables, so as to regulate exactly the angles of the two shafts. *Patent abandoned.*

903. H. Pooley, Jun. *Improvements in the construction of weighing machines and weigh bridges.* Dated March 31, 1862.

This invention relates to improvements upon that part of weighing machines and weigh bridges termed the steel yard or weigh beam. In the improved machines, by means of a compound poise or travelling weight, the patentee, firstly, dispenses altogether with the loose weights representing tons or hundred weights, as the case may be, and which in many of the ordinary weighing machines are placed on a counterpoise scale depending from a knife edge, which knife edge is immovably fixed into the extremity of the long arm of the steel yard; and, secondly, by a peculiar arrangement, he virtually elongates or contracts the said long arm of the steel yard, by which he secures a command over the balance never before attained either in range or per ancency. *Patent completed.*

904. W. M. Craustox. *Improvements in machinery for cutting corn and other crops.* (A communication.) Dated March 31, 1862.

This invention is not described apart from the drawings. *Patent completed.*

905. J. T. G. Stone. *An improved bustle and petticoat.* Dated April 1, 1862.

In carrying out this invention the inventor uses a flat band fitting round the waist, kept in shape by several semi-circular pieces of steel or metal, the said band having eyelet holes therein, through which the "steels" or wires of the bustle pass, such bustle being made of loops of steel, having the smallest loops at each end and the largest in the centre. To the said flat piece he also secures a petticoat, that is, he takes a sufficient number of lengths of the said steel, and, having formed them into loops or circles, he proceeds to fasten them to pieces of tape or ribbon in such manner that, when the upper ends of these tapes are fastened to the said bustle by eyelets or such like means, and the said bustle adjusted to the figure, the hoops or circles shall fall into or form a "full" under slip or petticoat, the largest circle or hoop in circumference being at the bottom, and the smallest being nearest the bustle. *Patent abandoned.*

906. P. R. Couchoud. *A loom for manufacturing chenille and other lace work.* Dated April 1, 1862.

Instead of making one chenille at a time, the patentee makes, on this loom, two, three, four, or more, and that without forming several guts or wires, one gut only being used for several chenilles if desired. The improved loom is composed, essentially, as follows:—The patentee employs several boards or cylindrical plates pierced with holes, and destined to receive an indefinite number of spindles of a large toothed wheel placed beneath, the two plates or boards receiving motion from the motor, and transmitting it throughout the mechanism of bobbins or spools which furnish the foundation wires or gut of the chenille. These threads or wires, to the number of two or more for each chenille, are intended to hold the cut threads of which the chenille is made. There are two or more endless cords turning round pulleys from the interior to the exterior of the machine or loom, and there is a fixed knife, or one having a come-and-go motion, cutting the girt which is formed by the silks leaving the spindles. There is or are one or more friction rollers to each chenille, intended not only to take and hold the chenille as it leaves the other side of the rod where the gut is formed, but the friction roller nearest the knife serves to approach and firmly hold the gut by the pressure of a screw spring or other mechanism, so that the knife may operate suitably. There are also two baskets or boxes into which the chenille falls, on having the pulleys placed in the upper part of the loom, and by the movement of which, and the play of toothed gearing for this object the chenille is twisted as desired. The invention also comprises a crank, band chain, toothed gearing, or similar means of setting the loom at work, and a pedal for stopping or setting the loom in motion, whether steam, horse, water, or other power be used. In the basket above mentioned is a compartment by which means the chenille which rises does not encounter that which descends. *Patent completed.*

907. C. P. Gontard. *An improved stopping-piece for watches and other time-keepers, intended to limit the winding up of the moving spring.* Dated April 1, 1862.

This invention is intended to supersede the organ applied in all time-pieces for winding up the main spring, and called by watchmakers the Maltese cross-shaped piece; the effect of the said piece being to prevent the breakage of the spring. By means of this improvement the barrel is fitted more firmly, and in a style more in accordance with the principles of mechanical science. It is submitted to less friction, it works better, it is more easily manufactured, and is so solid that its breakage seems impossible. The invention cannot be described without reference to the drawings. *Patent completed.*

908. W. Clark. *Improvements in the manufacture of manure.* (A communication.) Dated April 1, 1862.

This invention consists in the employment of peat of organic nature, like ordinary manure, which is rendered assimilable by an azoted fermentation, similar to that of an ordinary dung-heap, which is effected by adding azoted or earthy saline matters, such as blood, manure, urine, fecal matters, guano, animal detritus, ammoniacal salts furnishing azote, natural and fossil phosphates, such as bones, calcined or otherwise, ashes, vegetables furnishing earthy phosphates, sea-weed ashes, salt of soda or potash, either natural or artificial, for furnishing the necessary alkalies to the plants. *Patent completed.*

909. W. Clark. *Improvements in kneading machines.* (A communication.) Dated April 1, 1862.

This invention relates to an improved mechanical kneading machine for the manufacture of dough for bread or pastry. The inventor forms it of a trough, in which works an agitator or kneader for mixing the dough. The agitator is of a novel form, having no central shaft; it is composed of two curved right and left helical spirals formed of open bars. A rotating movement is imparted to this agitator by means of suitable gearing, which lifts the dough on both sides of the trough, throws it from one side to the other, and then allows it to fall between the open bars, during which it encloses the air contained. *Patent abandoned.*

911. W. Turner. *Improvements in machinery or apparatus employed in the manufacture of dough, and especially of fermented dough.* Dated April 1, 1862.

This invention consists of apparatus for the mixing of dough, in which standards or a frame made of wood, metal, or other convenient material, are or is employed for supporting the rest of the machinery or apparatus. On the upper part of these standards or frame are bearings in which run two cranked or other conveniently shaped shafts or axles, which said shafts or axles revolve in opposite directions. The patentee attaches to each shaft or axle an iron bar, rod, or arm, which bar, rod, or arm, as the aforesaid shaft or axle revolves, slides, or moves up and down in a slot; or the bar, rod, or arm itself may be slotted, in which case it would slide or move up and down on a pin or stud. The slot, pin, or stud, which may be provided with friction rollers, to facilitate the sliding or moving of the bar, rod, or arm, is attached to the standard or framework in a perpendicular line with the bearing carrying the shafts or axles. The bars, rods, or arms are employed for the purpose of communicating motion to the mixers in the mixing trough, the path or range of which said motion will be determined, partly by the distance at which the slot, pin, or stud is placed from the shaft or axle, and partly by the length of the bar, rod, or arm. He attaches to each arm a mixer, and these mixers are composed of bars of iron or wood, or other convenient material, which may cross each other at every revolution of the shaft or axle, or less frequently if desired. These mixers do not revolve on their own axis, but each of them passes through the dough, one in one direction and the other in an opposite direction, and thus will incorporate the flour with the liquid without the excessive manipulation which has been hitherto required, and is injurious to fermented dough. Power is communicated to the mixers without piercing the trough at either end, or at the sides thereof; the trough, therefore, is perfectly even throughout. *Patent completed.*

912. F. Knudsen. *Improvements in chronometers.* Dated April 1, 1862.

In carrying out this invention the inventor connects to the arms which carry the compensation bows what he calls auxiliary bows. Each of the auxiliary bows, like the primary bows, carries a weight or weights, the position of which upon the bows can be varied to adjust the balance correctly. The auxiliary bows are also, like the primary compensation bows, made of two metals, but the metals of which the auxiliary bows are composed are arranged in the reverse way to the metals composing the primary bows. The auxiliary bows will thus, upon an increase of temperature, move the weights carried by them away from the axis or arbor to which the arms carrying the bows are connected, and upon a decrease of temperature will move the weights towards the axis or arbor. The auxiliary bows will, therefore, tend to cause the chronometer to gain on a decrease of temperature, and to loose on an increase of temperature. The primary bows must, therefore, be made thinner to counteract this effect, and thus for a given variation in temperature the weights carried by them will move through a greater space. *Patent abandoned.*

913. H. SMITH. *Improvements in apparatus used when casting iron or other metal.* Dated April 1, 1862.

For the purposes of this invention a carriage or truck is used with upright and frames suitable for receiving a ladle between them. At the upper part of these end frames there are bearings for an axis, on which axis there is fixed a barrel on which is wound a chain to which the ladle is suspended. The axis is arranged nearer to one side of the carriage than the other, by preference, but it can be placed in the centre if required, and the end framings are strongly braced or connected together. On the axis is fixed a screw or worm wheel, which receives motion from a screw or worm on a suitable axis, on which is fixed a handle or hand wheel, by which motion is given to the axis of the screw or worm, and, consequently, to the barrel in order to raise or lower the ladle: or it may be raised or lowered by gearing or ratchet wheel and lever. To facilitate the tilting of the ladle, the tilting bar is received into hooks or bearings at the two ends of the arched frame or bar which is suspended by the chain on the barrel. The four wheels of the truck or carriage are suitable for running on a rail or tramway laid down between the cupola or other melting furnace and the place where the moulds are situated. *Patent completed.*

914. J. H. JOHNSON. *Improvements in machinery or apparatus for spinning cotton and other fibrous substances.* (A communication). Dated April 1, 1862.

This invention relates more particularly to what are known as mule spinning machines, and consists firstly, of an improved mode of driving the spindles, for which purpose a double-grooved wharve or pulley is fixed or formed upon the lower portion of each spindle, and one strand of an endless band is made to pass alternately upon opposite sides of the upper series of grooves, whilst the opposite strand of the same band is similarly passed round the opposite sides of the lower set of grooves of the series, both sides or strands of the endless band being thus made to operate equally upon the opposite side of each spindle. The band, before entering, and after leaving the series of wharves or pulleys is guided by stationary guide pulleys from and on to a larger grooved driving pulley situate at each end of the machine, motion being transmitted to the band at each end simultaneously. The second part of this invention consists of a peculiar construction of spindle which the inventor proposes to make much shorter than the ordinary spindles, and of a hollow or tubular section, in lieu of solid, excepting at the top and base. This spindle is supported upon a lower rail, and is steadied by being passed through two guide rails, situate above the supporting rail, parallel thereto. The third part of this invention consists of a peculiar form of the tip of the spindle, which it is proposed to make either conical or slightly rounded, and to form a helical slot or groove therein, into which the yarn enters, and passes thence into a small central aperture made vertically in the tip of the spindle, from which central point the yarn receives its twist, in place of passing or slipping over the end of the spindle at each revolution, as heretofore. The fourth part of this invention consists in lubricating the spindles by the application to the parts requiring lubrication of a piece of felt or other absorbent material saturated in oil or other good lubricant, such piece of saturated material being enclosed in a suitable box or receptacle provided with a hinged cover, which, when closed, will press the material gently against the part to be lubricated.

915. H. W. CASLON and G. FAGG. *Improvements in casting printing types, and in apparatus for rubbing the same.* Dated April 1, 1862.

This invention is not described apart from the drawings. *Patent completed.*

916. H. W. WHITEHEAD and G. BRAY. *Improvements in machinery for carding wool and other fibrous substances.* Dated April 1, 1862.

These improvements consist, firstly, in introducing between the cylinder or swift and the doffer of a condenser for carding, a revolving circular saw or roller armed with teeth, so that the teeth shall work within the spaces between the rings of "card clothing" on the doffer, and shall thereby effectually complete the separation of the strips of wool or other fibre, and shall detach from the doffer all wool which may be betwixt those spaces. The wool so detached will be delivered by the saw or roller on to the cylinder or swift, either directly or by means of a stripper, to be introduced for that purpose, and by this means will be mixed with the wool on the cylinder or swift, and returned with it on to the doffer, thus securing that all the wool shall be properly operated by the "card clothing." Secondly, in taking the wool from the doffer of a one-doffer condenser. The inventors propose to use a crank and doffing knife of the same construction, and to work in the same manner as the crank and doffing knife of any ordinary scribbler or carding machine, and to use only one such crank and doffing knife. They also propose to construct the grooved roller which receives the wool from the doffing knife with sharp angled grooves, instead of rounded grooves as heretofore. *Patent abandoned.*

917. E. HARTLEY, G. LITTLE, and J. HINCHCLIFFE. *Improvements in rolling or straightening metal spindles, shafts, or rods of a cylindrical or tapered form.* Dated April 1, 1862.

This invention consists in submitting spindles, shafts, or rods to the action of the rollers which extend in the direction of the length of the said articles, in combination with a stop piece, against which the articles are caused to abut. *Patent completed.*

918. J. PLATT and W. RICHARDSON. *Improvements in mules for spinning and doubling.* Dated April 1, 1862.

This invention relates to communicating the ordinary intermittent motion to the "change" or "cam shaft," for which purpose the inventors use an arrangement similar to that known in cotton machinery as the differential motion. *Patent abandoned.*

919. H. J. MADGE. *Improvements in coating iron sheets or plates, to be used as a substitute for tin or terne plates.* Dated April 1, 1862.

The patentee claims the use of antimony in producing alloys for coating metallic sheets or plates, to be used in place of tin or terne plates, as described. *Patent completed.*

920. J. PLATT and W. RICHARDSON. *Improvements in machinery or apparatus used for applying motive power derived from bullocks, horses, or other animals.* Dated April 1, 1862.

This invention consists in taking the power from two or more parts of the wheel to which the animals are connected. Thus the patentees employ a toothed wheel with internal or external teeth, carried by a vertical axis, and in connection therewith are two pinions connnected by gearing to a shaft by which the power is conveyed. The aforesaid wheel is provided with shafts or levers to which the animals are yoked, and beneath it are placed wheels or pulleys upon which it may be supported. To the rim of the wheel are connected beams which extend to the central shaft, and these beams are shut after the manner of roofing for buildings. *Patent completed.*

921. H LORENZ and T. VETTE. *Improvements in filters.* Dated April 1, 1862.

The first part of this invention consists in forming or producing hollow porous bodies or objects of charcoal, of any desired shape and size, but more especially in the form or shape of hollow balls, spheres, or shells. The hollow ball or other body is fitted with a socket, into which the short end of a syphon pipe is screwed, or otherwise secured, which communicates with the hollow space of the ball or other object. When thus fitted with a syphon, the said ball constitutes a complete and independent filtering apparatus, which can be applied to any vessel or holder of liquid, and put into immediate operation by the immersion of the ball in the liquid. The water or other liquid passing through the filtering medium or body of the ball rapidly fills the hollow space, and the syphon having been likewise filled by immersion or by suction, as usual, the water or other liquid will flow from the long end of the syphon on the tap being opened; not drop by drop, as in ordinary filters, but in a continuous stream, and with a rapidity proportionate to the surface of the ball or filtering medium. The second part of the invention has for its object to increase the purifying, disinfecting, and decolorizing properties of filters made and formed as above described, and it consists in filling, or partly filling, the hollow space in such filters with loose particles of prepared animal or vegetable charcoal. The third part of the invention consists in the application of the hollow ball or otherwise shaped body of filtering medium, as mentioned in parts first and second, to vessels or holders of liquid without the use of syphons. *Patent abandoned.*

922. W. C. HARRISON and H. J. STANLEY. *An improved instrument or tool for boring or drilling holes in slate or other rock.* Dated April 2, 1862.

The patentees claim feeding or supplying the cutter with water through a tube or channel, or tubes or channels, so as to deliver it at or contiguous to its point of contact with the rock, without interfering with the discharge of the débris, which arrangement not only prevents the cutter from being injuriously heated, but at the same time washes away and forces back the borings immediately they are detached from the rock, and prevents clogging. *Patent completed.*

923. G. HOLCROFT. *Improvements in the construction of blast furnaces.* Dated April 2, 1862.

This invention consists in gathering or contracting the lining above the enlarged space now generally formed around the tuyeres, and from this gathering or contracted part the remaining of the lining to the top is either parallel, contracted, or enlarged. The object of this peculiar form of the lining is to concentrate the gases, to prepare the charges in their descent down the upper part of the furnace, and to concentrate the heat at and below the gathering or contracted part for the purpose of more rapidly melting the charges. By enlarging gradually the upper portion of the lining, the deleterious gases can escape with facility. *Patent abandoned.*

924. G. SCRATTON. *Improvements in shades or blinds for windows.* Dated April 2, 1862.

This invention relates to improvements in shades or blinds for keeping the sun's direct rays off windows, the object being the obtainment of an improvement in the appearance of such blinds, whilst they admit a great amount of light through the windows, and permit of an agreeable prospect outwards. The improved shade or blind is composed of a series of narrow frames, covered with any suitable blind or shade material, each frame being disposed vertically, and at a shorter distance asunder, somewhat less than the width of the frame, the set forming a row in front of the window to be shaded. These shade or blind frames are sustained in position by pairs of parallel horizontal bars into which each frame hinges, one edge of each frame into one bar, and the other into the fellow bar. These bars are of equal length, and are fastened by turning pins (except in cases where the edges of one of the shades at each side of the window become the turning pins) to brackets or cross pieces fitted on to perpendicular spindles or side bars, one spindle or bar being placed on one side and one on the other side of the window. The spindles or bars turn freely in fixed brackets made to receive their ends or axle pins at the ends. If the shades be intended to be removable, the irons or brackets must be fastened to a perpendicular piece, one on each side, which pieces fasten and unfasten with hand screws, or studs, and slots to the wooden wold, or otherwise as the case may be. These perpendicular pieces may be joined at the top and bottom, so as to form a light frame. The shades are opened and closed or set to whatever inclination is required by turning the spindles or vertical side bars on their axes. Whatever motion is given to one spindle or bar is communicated to the other, and to all the intermediate shades simultaneously. *Patent completed.*

925. S. WARREN. *Improvements in machinery for transmitting motion obtained by animal power to agricultural and other machines.* Dated April 2, 1862.

This invention is not described apart from the drawings. *Patent completed.*

926. R. A. BROOMAN. *Improvements in memorandum, pocket, and other books, and in pencil and pen holders to be used therewith.* (A communication). Dated April 2, 1862.

The first part of this invention consists in making the covers of such books of a material such as slate, or other mineral or plastic substance, capable of receiving writing, and which may be removed, when desired, by washing or otherwise. One side of the book is composed, for example, of a sheet of natural or artificial slate, held on three sides in a metal frame carrying hooked gudgeons. To the back of the book a metal band is attached, beneath which the fourth side of the slate is slid; the ends of the band are bent to form slides in which the two hooked gudgeons take, and thereby render the frame solid with the band. By this means a fresh slate may be inserted when the old is used or broken. The other side of the book is made of card-board, wood, leather, or other material, carrying in the centre a metal frame in which a sheet of natural or artificial slate is placed; or both sides of the book may be made alike. The improvements in pencil and pen holders are as follows:— The ink holder is screwed on at one end of the case, and the pen holder acts as a stopper to it. A socket inside the case is screw-threaded at each end to receive either a black lead or a slate pencil. The pen holder is made hollow to contain a box for leads. The invention cannot be fully described without reference to the drawings. *Patent abandoned.*

927. W. MALAM. *An improvement in the manufacture of gas and improved apparatus to be employed in such manufacture.* Dated April 2, 1862.

According to this invention the inventor charges the retort without opening it, supplying it with coal or material in small quantities at a time gradually, and, if desired, continuously, and at a rate that may be regulated as required, so that the heat is maintained and concentrated in the retort, and is not uselessly absorbed, but expends its full working force on small quantities at a time, and the whole of the charge has its gas extracted from it. He generally feeds the retort at or about the centre, or from end to end. In the apparatus that he prefers to employ (though others may be used) a hopper is fitted to the retort with which it communicates by a passage leading thereto, and a feed or compartment wheel is placed between the hopper and retort. This wheel consists of a number of compartment or cells set round an axis; the section of the mouth of each cell is larger than the section of the feed opening or bottom of the hopper, so that, as the wheel revolves, each cell fills with coal which it carries down with it and discharges in the retort. *Patent abandoned.*

928. A. V. NEWTON. *Improvements in bits for taming or subduing vicious horses and breaking colts.* (A communication.) Dated April 2, 1862.

According to this invention the bit is formed of two bars, connected centrally by a pivot, so that they may expand and open, or distend the mouth of the animal, either by an automatic arrangement, or at the will of the rider or driver. *Patent completed.*

PROVISIONAL PROTECTIONS.

Dated July 30, 1862.

2157. F. C. Warlich, 10, Alma-terrace, New Cross, gentleman. Improvements in machinery for dressing and shaping stone. A communication.

Dated August 18, 1862.

2318. H. Boetius, 9, Roehampton-street, Besborough-gardens, Pimlico. Improvements in fire-proof materials.

Dated August 22, 1862.

2348. H. Twelvetrees, Bromley, manufacturer. Improvements in the preparation of washing powders, soap powders, and cleansing crystals.

Dated August 29, 1862.

2402. P. W. Mackenzie, Jersey City, New Jersey, and S. W. Smith, Brooklyn, New York. Improvements in vehicles to be propelled by the rider.

Dated September 4, 1862.

2444. J. Cook, Esq., 9, Fitzroy-place, Kentish Town. Improvements in carriages.

Dated September 17, 1862.

2552. W. and W. H. Watson, Harrogate, York, manufacturing chemists. An improved process or processes for the preparation of certain colouring matters from aniline.

Dated September 19, 1862.

2567. W. Tytherleigh, 28A, High-street, Marylebone, manufacturing ironmonger. An improved heater for ironing or pressing.

Dated September 25, 1862.

2614. F. Tolhausen, 17, Faubourg Montmartre, Paris, civil engineer. An improved steam cultivator. A communication.

Dated September 26, 1862.

2624. W. Pettet, Philadelphia, Pennsylvania, United States, merchant. An improved covering for protecting vessels and forts from shot, shell, and other warlike missiles. Partly a communication.

Dated September 29, 1862.

2638. R. Griffiths, 69, Mornington-road, Regent's Park, London, engineer. Improvements in the construction of iron ships and in the method of fastening metal sheathing thereon to keep them from fouling.

Dated September 30, 1862.

2651. R. Hoyle, Newchurch, Lancaster, woollen printer. Improvements in machinery or apparatus for printing surfaces of woollen, mohair, cotton, and other fabrics.

2653. J. L. Hughes, Droitwich-road, Worcester. Improvements in producing ornamental patterns in gold and colour on porcelain, earthenware, glass, and enamel.

2655. J. Wright, 12, Copthall-court, Throgmorton-street, civil engineer. An improved rotative travelling crane. A communication.

Dated October 1, 1862.

2657. P. G. V. Byl, 3, Upper Hyde Park Gardens. A power conserver brake for utilizing the power expended in stopping or retarding machinery, locomotive or other engines, and vehicles of any description when in motion. A communication.

2658. R. W. Greenwood, and C. J. Marson, 13, Gloster-crescent, Islington. A new and improved mode of using the exhaust steam of steam-engines by reconveying the same into the boiler.

2659. B. Donkin, Bermondsey, engineer. Improvements in bearing for shafts, axles, pivots, and sliding surfaces for the purpose of diminishing friction. A communication.

2661. W. C. Cambridge, Bristol, agricultural implement maker. Improved apparatus for washing clothes, applicable also as a churn.

Dated October 2, 1862.

2662. J. Gilchrist, Glasgow, consulting engineer. Improvements in boring engines such as are used for mining purposes.

2664. W. C. Wilkins, Long-acre, lighthouse engineer. Improvements in gas burners.

2665. E. Suckow and E. Habel, Manchester, engineers and machinists. Improvements in machinery for preparing, spinning, and doubling fibrous materials.

2666. J. H. Johnson, 47, Lincoln's-inn-fields, gentleman. Improvements in the permanent way of railways. A communication.

2667. G. J. Firmin, Millwall, Poplar. Improvements in the treatment of certain salts of potash and lime.

Dated October 3, 1862.

2668. F. Ensor, West Bromwich, ironfounder and machinist, and W. Payne, Birmingham, engineer. A new or improved apparatus for regulating the pressure of steam in steam boilers, and for indicating when the water in steam boilers is too high or too low.

2669. J. Harrop, Manchester, analytical chemist, and J. Wadsworth, Salford, machinist. Improvements in deodorizing refuse, organic, fecal, and urinous matters, and in a method of utilizing coal and other ashes, and in machinery or apparatus connected therewith, for producing a portable manure therefrom.

2670. T. J. Robotham, Burslem, chemist, and Edward Oswald, Stoke-upon-Trent, agent. Improvements in apparatus for purifying "glaze," "slip," or other potters' materials.

2671. R. Broadbent, commission agent, Leeds. Improvements in gas regulators.

2673. W. Clark, 53, Chancery-lane, engineer. An improved candlestick. A communication.

2674. W. E. Gedge, 11, Wellington-street, Strand. An improved suction and lift pump, and apparatus connected therewith. A communication.

2675. A. Dalrymple, 18, Eyre-street, Sheffield, clothier. Improvements in the processes of depositing metals by galvanic action either with or without the aid of galvanic batteries, and in the ornamentation of metal surfaces thereby.

2676. W. E. Gedge, 11, Wellington-street, Strand. An improved marquetry or veneer saw, and machinery or apparatus connected therewith. A communication.

2677. T. Greenwood, Leeds, machine maker. Improved machinery for cutting staves.

Dated October 4, 1862.

2678. J. and W. Lee, Humberstone-road, Leicester. Improvements in traction engines and boilers for traction, locomotive, and other purposes.

2679. W. H. Muntz, Millbrook, Hants. Improvements in armour for the protection of ships of war, and other vessels and fortifications, from the effects of cannon shot and other projectiles.

2680. A. Barclay, Caledonian Foundry, Kilmarnock, engineer. Improvements in printing textile materials and fabrics, and in machinery therefor.

2681. W. E. Gedge, 11, Wellington-street, Strand. Improved means or apparatus by the use of which pierced or perforated cocoons may be spun. A communication.

2682. S. Amphlet, Birmingham, manufacturer. An improvement or improvements in ornamenting surfaces of wood.

2683. J. E. Billups, Halswell-terrace, Cardiff. Fixed point for railways.

2685. F. Parkinson, 114, Wood-street, City. Improvements in ladies' shawls and cloaks.

2686. F. Watkins, Smethwick. Improvements in apparatus for milking cows.

2687. F. E. Blatspiel, Warwick Court. Improvements in diving apparatus, and apparatus to be used for working in deep water. A communication.

2690. F. Johnson, Great Charlotte-street, Landport, Portsmouth, French polisher. Improvements in domestic fire-escapes, and in receptacles for the same.

2691. W. Taylor, Oldham, cotton spinner, and S. Buckley, millwright. Improvements in machinery for preparing cotton and other fibrous materials.

Dated October 6, 1862.

2692. R. Page, Great Yarmouth, builder. Improvements in stables and stabling applicable in part to kennels, and to the floors of fish houses.

2694. J. Bradbury, Pendleton, mechanic, and W. Bradbury, Oldham, mechanic. Certain improvements in carding engines.

2695. D. Lowe, Aston, near Birmingham, manufacturer. Improvements in the manufacture of door bolts and latches.

2696. S. Holland, Oldbury, machinist. Improvements in machinery for the manufacture of bricks, drain, sanitary, and other pipes, tiles, quarries, and other articles of like manufacture, made from clay, marl, and other plastic substances.

2697. W. Clark, 53, Chancery-lane, engineer. Improvements in articles of clothing. A communication.

2698. J. Newnam, Crayford, manufacturer. Improvements in apparatus for crystalizing and for evaporating.

2699. T. Beards, Stowe, Buckingham. Improvements in machinery for cultivating land.

2700. S. F. Cox, Bristol, tanner. Improvements in washing and tanning hides and skins.

2701. A. V. Newton, 66, Chancery-lane, mechanical draughtsman. Improved apparatus for drying grain. A communication.

2702. C. Chinnock, Queen's-road West, Regent's Park, merchant. Improvements in the construction of axle-boxes.

Dated October 7, 1862.

2703. J. Heap, Ashton-under-Lyne, tool maker. Improvements in screw stocks and dies.

2704. J. Smith, Eedon, near Worcester, blacksmith. An improved screw linch-pin for carriages and agricultural implements.

2705. W. Aston, Princip-street Works, Birmingham, button manufacturer. Certain improvements in the manufacture of buttons for ladies' and gentlemen's wear.

2706. J. Oxley, Frome, Somerset, brewer's engineer. Improvements in apparatus for expressing and separating beer from yeast or barm.

2707. F. Rhales, Albert-street, professor of music. An improved safety envelope.

2708. A. Forbes, Canal-terrace, Aberdeen. Improvements in connecting together parts of vessels formed of tin and plate, and in the means or apparatus employed therein.

2709. J. D. Welch and A. P. Welch, Gutter-lane, straw hat manufacturers. Improvements in machinery for blocking and pressing hats and bonnets.

2710. H. D. P. Cunningham, Bury House, near Gosport, Esquire. Improvements in working the guns and in performing other necessary work on board ships, and in apparatus employed therein.

2713. A. V. Newton, 66, Chancery-lane, mechanical draughtsman. Improvements in the construction of condensers or coolers. A communication.

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

1713. C. Hook. Steam engines.
1714. J. Lovegrove. Inspecting small sewers and drains.
1726. J. Kinlock, and T. Edmeston. Looms.
1732. J. B. Ingle. Reaping and mowing machines. (A communication.)
1734. J. Shand, and S. Mason. Steam boilers.
1735. W. Lennan. Safety stirrup.
1736. J. D. Wake. Ships and vessels.
1737. H. Bland. Sewing machines.
1740. D. Crichton, W. Donbavand, and D. Crichton. Looms.
1746. J. Ingham, and W. P. Wood. Preparing colouring matters.
1752. A. Salviati. Gold and other precious metals. (A communication.)
1759. J. H. Glew. Sewing machines.
1773. W. Bouch. Cranes.
1774. R. A. Brooman. Cooking ovens. (A communication.)
1776. R. Hicks. Manufacture or preparation of paints, pigments, and colours.
1787. J. Hunt. Bronzing or colouring articles of copper or alloys of copper.
1799. J. Warren. Ploughs.
1805. A. Howat. Water gauges.
1811. E. J. Davis. Food for animals.
1814. W. Jeffries. Rail for railways.
1820. D. Adamson, and L. Leigh. Construction of steam boilers.
1832. H. and J. Davenport. Loom healds or harness.
1840. J. Lawson. Manufacture of carpets.
1841. E. Edmonds. Manufacture of felted articles. (A communication.)
1842. T. Wilson. Dress fastening.
1846. A. Webster. Boring slate.
1847. W. Barr. Manufacture of raised or brocaded fabrics.
1862. W. Clark. Ploughs. (A communication.)
1867. E. H. Huch, and F. J. Windhausen. Caloric engines.
1868. J. Whitham. Hydraulic presses.
1875. T. R. Tebbutt. Manufacture of soap.
1919. G. H. Birkbeck. Utilization of certain refuse. (A communication.)
1938. G. H. Birkbeck. Construction of mechanical horses. (A communication.)
2020. S. Partridge. Railway signals.
2286. G. White. F. Buckland, and C. Rees. Water-closets.
2401. W. Owen. Manufacture of railway wheels.
2444. J. Cook. Carriages.
2513. J. Thom. Mounting or fitting artificial teeth.
2516. J. Rowell. Pillars and apparatus for straining wire.
2582. L. Dixey, and G. Smith. Improved method of tinting.
2633. H. Hutchinson. Covering wire with india-rubber and gutta-percha. (A communication.)

The full titles of the patents in the above list can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list who have given notice of their intention to proceed, within twenty-one days from the date of the *Gazette* in which the notice appears, by leaving at the Commissioners' office particulars in writing of the objection to the application.

PATENTS ON WHICH THE STAMP DUTY OF £50 HAS BEEN PAID.

2357. J. H. Brown.
2380. J. Higgins and T. S. Whitworth.
2396. J. Bruckshaw, H. Bruckshaw, and W. S. Underhill.
2364. S. Newberry and H. Moore.
2385. A. S. Rott.
2398. R. Hobson.
2448. J. W. Hackworth.
2414. P. Jones.
2462. R. A. Brooman.

PATENTS ON WHICH THE STAMP DUTY OF £100. HAS BEEN PAID.

2354. T. Valentine, D. Foster, and G. Haworth.
2311. E. Wilkinson.
2336. S. Statham.
2345. W. Basford.

LIST OF SEALED PATENTS.

Sealed October 17, 1862.

1136. R. Dennison.
1141. R. and G. Stuart, and H. Hill.
1142. B. Rhodes.
1146. W. Rose.
1151. A. P. Tronchon.
1153. E. H. C. Monckton.
1159. R. A. Brooman.
1161. T. Attwood.
1165. C. C. Creeke.
1166. T. Lea, and S. Smith.
1167. E. H. C. Monckton.
1177. W. Moir.
1178. G. N. Bates.
1180. W. Carpenter.
1184. A. Hodgkinson.
1186. G. T. Bousfield.
1191. J. Endean.
1196. J. Winsborrow.
1197. G. Davies.
1201. F. Dangerfield.
1215. J. Shaw.
1223. E. A. L. Negretti, and J. W. Zambra.
1228. J. G. N. Alleyne.
1233. A. Boyle, and T. Warwick.
1263. M. Henry.
1275. J. Oxley.
1324. P. V. Lefebvre.
1329. T. Wilson.
1361. T. Markland.
1364. N. Wood, and J. Stockley.
1900. C. Callebaut.
1912. W. Easton, and G. Donkin.
1990. E. Townsend.
2052. O. F. Morrill.
2067. W. Tranter.
2075. W. Clark.
2097. W. Clark.
2104. H. Rawson, and F. Staples.
2256. C. A. Wheeler.
2267. J. Cooper.

THE
MECHANICS' MAGAZINE.

LONDON, FRIDAY, OCTOBER 31, 1862.

IRON WALLS AND NAVAL GUNS.

TO THE EDITOR OF THE "MECHANICS MAGAZINE."

GUN TOWER SHIPS.

SIR,—I will devote the space accorded to me in your columns this week to the consideration of cupola or revolving tower ships. That form of armour-plated structure for naval warfare is attaining much importance. The Federal Americans, who, already possess four or five iron-cased vessels on the "Monitor" plan, are building twenty or thirty more of a similar description, varying in size and in details of construction and armament, but all on the revolving-turret principle. We are building two cupola ships on Captain Coles's plan, one, the "Royal Sovereign," a wooden vessel, at the Portsmouth Dockyard, the other an iron vessel, at Mr. Samuda's yard. The Confederates give the preference to the "Merrimac" plan of covering the vessel with a sloping iron roof, and so far as we know, they have not adopted the cupola system. The French, it has been stated, after a careful examination of the gun-tower principle, have decided upon not making use of it, the French Ordnance Committee, and the Emperor himself, it is alleged, having come to the conclusion that the inconveniences, difficulties, and dangers of the plan, in a practical view, over-balance any advantages it may possess.

The *Times* has recently given prominence to this question. The editor of that powerful journal is too grand and lofty to acknowledge my criticisms of its naval intelligence, but the arguments in his recent articles on this subject afford unmistakeable evidence that I have induced him to consider the subject of heavy naval guns, and to modify his opinion. I cannot, however, compliment him on his knowledge of the subject or the logic of his reasoning.

Only a few days ago, the *Times* deliberately asserted, "we have not a vessel *which will carry* a seven-ton gun." To which I replied that the "Warrior" will carry, not only a 7-ton gun, but a number of 12 or even 24-ton guns. That journal now makes the discovery that ships may be produced which will carry those heavy guns, and announces that the "Royal Sovereign" is to be armed with 12-ton Armstrong's; and it sees no reason why a vessel should not carry five 20-ton guns as readily as twenty 5-ton guns. That was precisely my argument, which the *Times* now indorses, after having dogmatically maintained "that a gun of 95 cwt. is the heaviest that can be worked with success, or even safety, on board a floating vessel." We shall agree by-and-bye; the great journal is famous for its versatility, and ere long it will *frankly* admit that ships now afloat, such as "La Couronne" and "La Normandie," can and will be armed with those terrible 150 and 300-pounders, which would smash in the sides of the "Warrior," if in action she is armour-plated after her present fashion. I am determined to afford all the help I can to tear away the scales from the eyes of the Lords of the Admiralty; and, despite the advocacy of the leading journal, enable them to see the gulf of perdition into which they will cast the naval reputation of England, if they do not adopt a more efficient system of naval armour than 4 or 5 in. of iron plate on wooden planks.

The *Times* tries to escape from the dilemma in which it involved itself by its too reckless attempts to prove the invulnerability of the "Warrior." It admits that cupola or tower-ships may carry 12 or 24-ton guns, but it maintains that vessels built on the ordinary principle cannot. At this point I join issue, and I submit that those remarks prove that the writer of the articles, which lately appeared in the *Times* on heavy naval guns and cupola ships is not well posted, (to use a Yankeeism) on the subject, which he affects to decide upon *ex cathedra*. He has confounded the carrying capacity of a ship with the platform and deck arrangements for bedding and training the guns, and he has not perceived the distinction between displacement or floating capacity and gravitation which deermines her stiffness in the water. The higher the centre of gravity the more the vessel will roll. The lower the centre of gravity the steadier she will be. The "awful rolling," for which the "Warrior" is so celebrated, is caused by the heavy armour plates and guns overhanging her top sides and raising the centre of gravity, on which she oscillates to an elevated point above her keel.

With the centre of gravity lowered and a smaller amount of oscillation the guns practically for fighting purposes might be more out of the water at an elevation of 7 ft. than they would be at 9 ft. above the load line. The "Warrior," like the "Royal Sovereign," possesses the capacity of carrying 12-ton or 24-ton guns, and her superior tonnage enables her to carry a larger number without altering her displacement or trim; but she would not carry them so conveniently as the latter vessel, although, with the same weight of metal as her present armament in heavier guns, she would probably labour less than she now does.

The 40 guns of the "Warrior," taking them in round numbers at 5 tons each, weigh 200 tons. Ten guns of 20 tons each would be the same weight. It of course can make no difference in displacement whether this weight be distributed in 10 large or 40 small masses. The former, like the latter, can be equally distributed from stem to stern along both sides of the vessel, so that the centre of gravity and the angle of oscillation would be the same in both cases. The only modification required for the heavier guns would be the construction of larger and stronger platforms or beds, with more substantial supports under the gun deck, and some simple mechanical contrivance to facilitate the working of the guns. Taking all things into account, there seems to be little doubt, that the ten 20-ton guns could be worked with a smaller number of men, and more commodiously, considering the greatly enlarged space for each gun, than the forty 5-ton guns.

Placing guns along the centre of the deck, as in the plan of construction of the "Royal Sovereign, is referred to by the *Times* as if that arrangement enabled the vessel to *carry* heavy guns. But this is palpably a mistake. The carrying power of the ship is not augmented by placing the weight of the guns amidships; that power, as before stated, is simply a question of displacement. But the effect of the disposition of the guns and iron towers along the centre of the deck, as in the "Royal Sovereign," is to enable the vessel to carry the weight of her guns and armour more commodiously. This, no doubt, is a great advantage. The sides of the ship above the load-line being relieved from a notable portion of their burden, she will stand up stiffer, she will roll less, and steer better—all valuable points for a sea-going ship; but in a cupola iron-clad, on the plan of the "Monitor" or "Royal Sovereign," the advantages, as I will show hereafter, are gained at a terrible sacrifice of the comfort and confidence of the crew, and the efficiency of the ship, by restricting the cabin and fighting space, and discouraging the sailors when in action. The moral effect on eight or ten men to one gun, shut up in an iron box, and cut off from the rest of the crew, will tell prejudicially on the spirits of the men, and the working of the guns in a close conflict.

There can be no doubt, for the reasons above stated, that the disposition of heavy guns along a central line fore and aft, which is effected by Captain Coles's plan, is a decided advantage; but this advantage must not be confounded with the revolving tower system. To determine the precise character of his invention under its different aspects, the position of the guns and the round tower principle, whether rotating or fixed, must be considered separately. Neither has any necessary connection with the other. Either plan may be carried into effect by itself apart from the other. Some of the inconveniences of working one or two pieces of heavy ordnance within the narrow limits of an iron chamber, with just space enough to train the guns, have been referred to. But there are other serious objections. If a gun should burst, the effect would be terrible; every man in the tower would be killed or mutilated. The fighting force, the best men in action, are subdivided into small sections, completely isolated from each other, which in warfare is the worst system of tactics. One hundred gunners, manning the guns on one deck, encouraging and stimulating one another by mutual aid and example, would be more effective in a hotly-contested battle at close quarters than double that number in ten detached towers. The upper deck of a cupola ship is peculiarly unsuited for repelling boarders or attacking an enemy by boarding. The crew cannot be suddenly and simultaneously withdrawn from and returned to their quarters on the gun-deck. The men, having no bulwarks to protect them, cannot remain on the upper deck exposed to the fire of musketry and grape, and yet a vigilant and constant guard of the upper deck in close action is indispensable, because a cupola ship is peculiarly susceptible to assault by boarding. If the enemy once got possession of that deck, it would be difficult to drive them off, and a few men might wedge up the towers so as to prevent their rotation, and render the guns useless. The successful working of the machinery for the rotary motion in the heat of action, is by no means to be depended upon; an accident to the mechanism for training a gun would render it unserviceable. As broadside guns at close quarters, the Coles cupola system will be inefficient for pointing them between wind and water. This objection, in adapting the "Royal Sovereign" as a cupola ship, became so palpable that, after she was cut down, it was found that the *maximum* depression range of the guns would be so small, that it was necessary to raise the gun platform deck several feet, and new upper deck beams and frames, to carry the towers at a higher elevation, had to be constructed. By this alteration the last-mentioned objection is in some measure abated, but not removed, and it must always remain one of a serious character.

In fact the cupola scheme was suddenly brought into notice by the gallant onslaught of the "Monitor" on the "Merrimac," but her success at most was negative, and the critical position of her crew was proved by their state of exhaustion from the want of ventilation. The designer of the closed tower

shield is so sensible of this alarming defect that he has found it necessary to contrive a system of ventilation by blowing a stream of air from below through openings in the crown of the shield. Here is another mechanical device, the failure of which, in the heat of action, would incapacitate the men from standing to their guns.

I fear that the plan of fighting guns singly inside detached towers on the deck of a vessel, as planned by Captain Coles and the constructors of the "Monitor," will, when tested by actual warfare, prove to be a complete failure; and, however unfit to encounter heavy guns, the armour and armament of the "Warriors" and "Northumberlands" may be, I believe England has nothing to fear from the American iron-cased navy, so long as that government does not adopt a better model than that of the "Monitor." I am also of opinion that the "Royal Sovereign" will never be the model of an efficient class of war ships in the British service. In consequence of the difficulties of construction and adaptation, which becomes apparent as the work proceeds, as well as the serious nature of some of the defects, I have pointed out, it is by no means certain the "Royal Sovereign" will be completed, or, at all events be relied upon for actual service, until she has undergone some radical changes in the original design of the inventor.

In this cupola ship case we have another example of the total want of method and consistency which prevail at the Admiralty. Four years ago, the plan was brought deliberately under their notice, and although the inventor is an ingenious and meritorious officer, it was ignored by the board, and all his efforts were in vain to obtain even an experimental trial. To make the matter worse, a cupola shield, which was constructed by Mr. Scott Russell, was allowed to remain untried and unfinished more than a year. Suddenly, in a moment of excitement, the cupola is forced on the Admiralty, which then takes immediate action in the most inconsiderate manner. After some hasty experiments with the long neglected trial cupola, which gave anything but satisfactory results, a bargain was suddenly struck with Captain Coles, who received the sum of £5,000; and two tower ships were ordered to be built. I do not remember the estimates of these vessels, but they probably will not cost less than £200,000 to £300,000. Now how much wiser and more economical it would have been to have thoroughly investigated Captain Coles's proposals 3 years ago, and submitted his plan to actual trial, on an efficient scale, before committing the country to the heavy expenditure incurred. Less than £5,000 spent on a full-sized cupola, fixed on a hulk, and a series of experiments against it with heavy guns, would have settled the question of the merits of the plan, or have suggested some notable improvements; but that is not the Admiralty method. That inscrutable department prefers an expenditure of a quarter or half a million on *experimental ships* to the prudent forethought of preliminary trials, of promising plans at an expense of a few thousand pounds. Instead of that obvious rule of prudence, which ought to make the Admiralty act with liberality in target trials, it jesuitically refuses the funds for experiments recommended by its own committee, on the plea of economy, or under false pretences; whilst, *without any previous trials*, it rushes into an outlay of millions on a system of naval armour which, after eight or ten ships are built, and twenty more contracted for, is ascertained by experiment to be worthless.

In the remarks I have made on Captain Coles's plan, I am far from wishing to underrate the ability or merit of that officer. He deserves the remuneration he has received for the ingenuity of his conception and the independence with which, regardless of the professional disfavour he provoked in high quarters, he persisted in urging on the Government the trial of a plan which he thinks beneficial to the service. Great credit is due to him for initiating an improvement in floating batteries, by placing the armament in the centre of the vessel fore and aft, but I think he is mistaken in his mode of applying the principle.

CIVILIAN.

HOW TO PREVENT RAILWAY ACCIDENTS.

In another part of the Magazine will be found the substance of a paper read by Mr. John Sewell, in one of the sections at the British Association's recent meeting at Cambridge. There is no doubt that the writer of the paper in question has dealt therein with some practical points in connection with the economy of the railways, which are of much importance, and we are aware that his information has been gained in the school of experience. Still, we confess to a feeling of disappointment in its perusal. Mr. Sewell has lost sight altogether, so far as his paper is concerned, of at least two very momentous points in connection with the safety of railway travelling. He tells us that the "primary cause of most of the serious "railway accidents is, that railway companies "are not liable either for overloading their "engines or for not keeping time at all the "stations." This, indeed, is the burden of his song throughout the whole of the paper. Mr. Sewell tells us nothing of the absolute essentiality of a complete and unmistakeable code of signals on any line of railway, or the necessity for an improved system of brakes for bringing rapidly-running trains to a sharp and sudden standstill. Yet the imperfections existing in both these particulars are, we venture to say, as fruitful sources of accident as are those referred to in Section G. of the British Association. The recent accident at Market Harborough is a case in point; and though the coroner's inquest resulted in a verdict of Manslaughter against the driver of the engine of the second train, Ezra Stubbs, yet it is pretty clear that the signals in and near the station were much at fault. It were needless to expatiate upon the second disadvantage to which we have adverted, that of imperfect brake-power in railway trams. Much ingenuity has been expended by practical mechanics and others in devising modes of checking trains running at high speeds, but it is a fact that Railway Companies have not encouraged with that earnestness and liberality which in such a cause they ought to have exhibited the efforts of inventors. Had Mr. Sewell, who has earned many mechanical laurels in times past, and whose career has been that of a patient, painstaking, and persevering worker, both with hand and with head, given the public the benefit of his knowledge of railway signals and brakes, their faults and failings, he would have made his paper far more perfect than it is. Now that the metropolis is being intersected at all points and undermined at several railways, and that Mr. Sewell's "Iron horse" is careering in all directions about the metropolis, it is more than ever necessary that a uniform code of signals, simple in character and in action, should be established, and that the movements of the "horse" should be governed completely by the grooms, so as to speak, who sit behind the animal.

Excepting the omissions of which we complain, Mr. Sewell's paper is entitled to consideration, and if that gentlemen chooses to supplement his views by touching upon the points we have named, our columns are open to him for that purpose.

Reviews.

A Treatise on the Principles of Electrical Accumulation and Conduction. By F. C. Webb, Associate of the Institution of Civil Engineers. Part 1. London: E. and F. N. Spon, Bucklersbury.

It is but seldom we have to notice anything strikingly novel or original in the form of a treatise on electrical science. Works on electricity are for the most part mere compilations, and the authors generally appear to copy and follow each other without much difference of opinion or novelty of doctrine. The present work however will afford some new and interesting views of electrical phenomena to those who study the latter from a mathematical, or, rather, from a geometrical point of view; that is to say, to a large section of inquirers in this branch of science. In the first part, which we now have before us, the difficult questions relating to Electrical Accumulation are brought within the reach of rule and number, and the practical electrician is shewn that he may calculate the resistance to Electrical Accumulation, in much the same manner as he calculates the resistance to Electrical Conduction. It will be perceived, from what we have said, that the work is intended for the more advanced student of electrical science, rather than for the beginner, who might expect to find in it descriptions of electrical machines and batteries, or the details of electrical manipulation.

We may follow the author through a few of the first steps of the work, which will be sufficient to show the general character of this contribution to our electrical knowledge. We commence with the fundamental axiom, that "Whenever electrical generation occurs, whether by chemical, frictional, or thermal action, exactly equal amounts of electrical action of opposite nature occur on the opposite sides of the source of generation." If we require to obtain in a free state a certain quantity of *plus* electricity, termed also vitreous electricity by those who hold the double-fluid theory, we may readily produce it by means of the electrical machine or the voltaic battery; but we necessarily at the same time liberate an equal quantity of *minus* or resinous electricity. We may, therefore, at the same time that we "accumulate" the plus electricity upon an insulated conductor, obtain the minus electricity as a charge upon a similar conductor. In so doing, however, we find a greater difficulty in obtaining a charge of given amount, or we require a higher electrical intensity than if we connected one "side of the source of generation" to an insulated conductor, and the other to earth. The reason of this will be found explained at p. 66, *et seq.* The readiest means of charging a conductor, say with plus electricity, is to connect to earth the rubber of the electrical machine, or the negative pole of the battery, and to establish a conducting communication between the prime conductor of the machine or the positive pole of the battery, and the body upon which the electricity is to be accumulated.

This brings us to a point upon which Mr. Webb lays great stress, and which indeed is one of considerable importance in regard to the due appreciation of some of the main points of electrical theory. What becomes of the electricity generated on that side of the source which is connected to earth? The great majority of writers, among whom are Prof.

Daniell, Sir W. Snow Harris, and Messrs. Lardner and Walker, assume that this electricity becomes distributed over the indefinitely large surface of the earth, and is thus "virtually annihilated." The author, on the other hand, maintains that it becomes accumulated upon the nearest conductors surrounding the body which is charged with the opposite electricity. "The electricity generated at that side of the source in connection with the earth is as much conducted to and distributed over the adjacent opposing conducting surfaces as the other electricity is spread over the insulated conductor, and thus the outer opposing surface is in every respect as much a charged surface as the prime conductor, the difference being only one of degree." The following experiment is suggested as being calculated to decide the question:—An electrical machine is placed within an *insulated room*, the rubber of the machine being connected to the walls. Upon charging the prime conductor with positive electricity from the excited glass disc of the machine, the inner surface of the conducting material of which the room is formed acquires a negative charge of exactly the same quantity as the charge upon the prime conductor. That this is the case would be shown by bringing this conductor into conductive communication with the walls of the room, thereby neutralizing the charges and removing from both surfaces every trace of free electricity. Now, if the room be uninsulated or connected to earth, we have ample evidence to prove that the effect of charging the prime conductor of the machine would be precisely the same as under the former conditions, the inner surface of the chamber becoming negatively charged, and none of the negative electricity generated being conducted to earth and distributed over its surface.

The assumption that every time a conductor is charged with plus electricity, the negative charge is distributed over the whole surface of the earth, is clearly untenable; and Mr. Webb has rendered a service to electrical science in clearly pointing this out. In every case we find that the opposite electricity becomes accumulated at the nearest possible distance from the surface of a charged conductor. The conditions which prevail in a charged Leyden condenser are common, therefore, to every instance of electrical accumulation. In the Leyden jar, the distance, or thickness of the dielectric, between the oppositely-charged surfaces, which determines the "inductive resistance" to charge, is inconsiderable; and the quantity of the opposite electricities which can be accumulated, under a given intensity, upon the conductive surfaces, is therefore comparatively great. The term inductive resistance is employed to express the converse of what is known as "inductive capacity." A formula for the inductive resistance of cylinders, derived from the well-known expression of Ohm for prismatic resistances (R = ;), has already been given by M. Gaugain, who, as Mr. Webb observes in the introductory notice to his work, has pointed out the general applicability of Ohm's law to problems of electrical accumulation. Messrs. Thomson, Siemens, and Varley have also adopted, to a certain extent, the method of treating the resistance to accumulation in the same manner as Ohm has treated the resistance to conduction, a method which forms the principal characteristic of the present portion of Mr. Webb's treatise.

The Albert Memorial Committee of Bath have entrusted to Mr. Matthew Noble the execution of a colossal bust of the late Prince Consort, which is to be placed in the new building to be added to the Bath United Hospital.

CIVIL AND MECHANICAL ENGINEER'S SOCIETY.

F. CAMPIN, ESQ., C.E., IN THE CHAIR.

"ON SETTING OUT RAILWAY WORKS."

BY G. J. CROSBIE DAWSON.

October 23rd, 1862.—The author commenced by observing that railway making in England has been carried on to so great an extent, especially since the memorable year 1845, that after looking at a map of England shewing the existing and authorized lines, there does not seem space left anywhere for new ones, and yet there were no less than 170 plans for proposed railway schemes deposited at the private bill office for last session, proposing the construction of 1,800 miles of new line in the United Kingdom, of which 1,497 miles are in England.

But this state of things cannot go on very much longer, for in a few years time there will be no need of more lines, and the railway engineer, if he still wishes to practice in that branch of the profession, must go off to India, Australia, or New Zealand, where he will have a wide field before him; or he must go to some foreign country, for strange to say, most of the foreign railways have been, and are being made by English engineers. There were at the end of the year 1861, 10,433 miles of railway in the British Islands, and comparing the progress of the railway system in England with that of other countries, we find that with the exception of America, we have many more miles of railway in England than in any other country.

The author then went on to say that of course a great deal depended on the selection of the best line of railway to be obtained, which necessarily involves a great deal of time and trouble, and should be guided by many circumstances, the principal object being generally the connection of two distant towns, or the joining of two lines of railway by means of a branch from one, or of affording accommodation to smaller towns not on the main line by means of branch lines. To obtain the most direct route is of course desirable; this, "as the crow flies," would evidently be a straight line, which, in the generality of cases, would be quite impracticable, as there are other requisites of as much importance to be considered of. Therefore, as it is next to impossible to get a perfectly straight line, a railway must consist of a system of curves and straight lines, the curves being of such radii and flexure as will suit the nature of the country as regards the levels, the towns lying in the vicinity of the main line, and the keeping intact of valuable property, &c.

Since all moving bodies have a tendency to preserve their motion in a direct line, sharp curves on a railway are highly objectionable, as the centrifugal force arising upon them tends to throw the train off the rails, especially one of great velocity, which would be strongly impelled towards the exterior rail, and would, were it not prevented by the flanges of the wheels and the conical inclination of their tyre, run off the rails altogether. This conical inclination of the tyre of the wheels, which increases the diameter of the outer, and diminishes that of the inner wheels, and which causes the train to roll on a conical surface, generates, except in curves of very small radii, a centripetal force to counteract the centrifugal. But, however, this is not enough to counteract the force in curves of very small radii, and a superelevation of the exterior rail is required for the purpose, which in a curve of 30 chains radius would be about 1½ in., if the rate of the train was about 30 miles an hour. Therefore, of course, the flatter the curves are the better. The least objectionable situation for them is at the extremities of the line, or stations on the level where all trains stop, where they frequently occur of about ten chains radius or less, but on gradients, or in tunnels, they are most certainly to be avoided as being very dangerous, the undesirableness of them also increases with the speed of the train. Mr. Brees says that a rise of 16 ft. per mile or 1 in 330 upon a curve of three-quarters of a mile radius, reduced the speed of a locomotive to nearly one-half.

On the Great Western Railway the curves are very flat indeed; Mr. Brunel objecting to any under one-mile radius; indeed he considered that undesirable, and for the most part they are of 4, 5, and 6 miles radius, unless close to a large station. Mr. Stephenson was also for flat curves, the radii of them being, on the old London and Birmingham Railway generally exeeding a mile. Now, finding that they are practicable, we have them very much sharper, as is necessary in many instances. On the Chester and Crewe, line there is a curve of 18 chains radius at the Crewe terminus; and the Grand Junction joins the Liverpool and Manchester line in 2 curves of 10 chains radius each; on the Newcastle and Carlisle Railway there are two curves of 10 chains radius, which are traversed constantly by trains at the usual speed; and on the Taff Vale Railway there are curves of 7 and 10, and several of 15 and 20 chains radius, and, indeed, a great many of the branches now made have curves as sharp. Where the Crystal Palace Railway, after running by the side of the South Western, suddenly curves round and passes at right angles under it, just before crossing the Thames into Victoria station, the radius is about 20 chains, and very shortly there will be as much traffic over it as on any line in England; for when the West London Extension Railway is opened, there will be trains from the London and North Western, and the Great Western Railways, as well as the Brighton and South Coast and Crystal Palace traffic.

The author next called attention to the subject of gradients, remarking that they ought to be such as to render the works as light and inexpensive as possible, due regard being paid as to how much earthwork, tunnelling, viaduct, and bridge work may be saved consistently with the required velocity, the expenses of engine power, and the general wear and tear of the rolling stock and brakes. Of course, if the gradients are steep, there will be a less amount of earthwork in the cuttings and embankments, and less land will be required; also, the viaducts and tunnels will be shorter, whereby there will be a saving both in labour and expense; but this must be carefully weighed with the expense in locomotive power, repairs, and speed, &c., attendant on it.

A few years back steep gradients were thought to be quite impracticable by almost all the engineers, the ruling gradient on the London and North Western being 1 in 330, or 16 ft. per mile; on the Great Western Railway they are mostly 1 in 1,320, or 4 ft. per mile, though there are one or two at 1 in 660; and the Box tunnel and Wootton Basset inclines are 1 in 100. It was Mr. Joseph Locke who first attempted sharper gradients, making his lines suit the surface of the country, instead of the reverse, as was the custom before. He practically demonstrated that inclines of less than 1 in 100 could be safely and economically worked; but all the European engineers of the day regarded such an attempt as a very bold and hazardous experiment. Navier, and the whole school of French engineers, opposed *in toto* the admission of inclines of less than 1 in 200. But, however, owing in a great measure to the wonderful improvements in the manufacture of locomotives, many of which were no doubt due to Mr. Locke, gradients of 1 in 100, and very much steeper, have been successfully adopted. There is a gradient on the direct Portmouth of 1 in 80 for a length of 6 miles, and another on the Caledonian of 1 in 70 for 2 or 3 miles. The fall into Euston Station, on the London and North Western, is at the rate of 80 feet per mile, or 1 in 66. The author then, after enumerating several of the steepest gradients on the various railways, said that a short time ago there was a gradient of 1 in 25, or thereabouts, on the West London Railway, between the London and North Western and Great Western Railways, and that he, with some friends of his, saw in December, 1859, an engine

draw 40 empty waggons up it, but the line has since been altogether altered. Mr. Vignoles states that scarcely once in 20 times does a locomotive engine go out with more than half its load; and, as a general rule, engines are only worked up to two-fifths of their power, and therefore that railways, in his opinion, should be made in the cheapest manner, without minding stiffish gradients, as on extraordinary cases an additional engine could be put on. If possible the stations should be on the summit of two gradients, as they would tend to stop the train coming in, and to accelerate its starting: a piece of level should also always be inserted between two gradients inclining different ways, and care should be taken that there is no useless loss of power.

The author, then, after mentioning some interesting experiments made by Dr. Lardner, on heavy gradients some years ago, proceeded to the more practical part of his paper. He entered fully into the particulars of the large detail survey for the contract plans and sections, observing that the Parliamentary Plan was quite useless for setting out the line by being plotted to such a small scale, 5 chains to the inch being usually the largest to which they are plotted; indeed, 4 inches to the mile is a very favourite scale, being the smallest allowed by standing orders; and also that for the most part they are not of sufficient accuracy, being got up in such an incredibly short time, and sometimes even patched up and "cooked" from old tithe maps, &c., the surveyors working night and day in the dismal month of November to save their deposits on the 30th. The detail survey having been made, the engineer, previous to the final setting out of the centre line, should exercise all his judgment in making any improvements that are possible for economising the construction of the works, &c., by a more correct balancing of the cuttings and embankments, or shortening of any viaduct or tunnel, &c., for which purpose he should carefully examine the ground with the plan and section in his hand. Of course, particular attention must be paid to every road crossed by the railway, as also the most suitable site for the stations and approach roads, &c., not forgetting the important question of drainage.

The author then proceeded to explain the method of setting and staking out the centre line, calling particular attention to the ranging out of curves. He gave several examples: one by which the curve is set out by means of theodolite angles and a chain; a second in which a chain, a few ranging poles, and an offset rod is all that is required; and another where two theodolites are required, supposing obstructions occur preventing the use of the chain, which last method he took from Baker's "Railway Engineering."

He then entered fully into the staking and nicking out of the centre line, and taking the levels for the contract section, as also for the cross sections, observing that permanent posts should be fixed into the ground—to have bench marks on for reference to levels at future periods, when all the other pegs have been removed—at certain convenient points, such as near the sites of bridges and culverts, &c., or near the commencement of excavations or embankments.

The author next explained the methods of setting out the widths, both on level and sidelong ground, and concluded his paper with a few remarks on the nature of the strata in embankments and cuttings, giving the angles that the various formations will stand at. The paper was illustrated by several large diagrams.

It has been decided to allow the Loan Collection of Works of Art, now exhibiting at the South Kensington Museum, to remain open in its present entirety, until about the time when the International Exhibition closes. Shortly after this date, a certain number of the articles, such as the gold and silver plate belonging to the numerous bodies contributing, will be returned. The extreme liberality of many private owners of large and valuable collections will, we understand, lead them to allow their treasures to remain before the public for a somewhat longer period.

INTERNATIONAL EXHIBITION. JURY REPORTS.

CLASS VIII.—MACHINERY IN GENERAL.

(*Continued from page 250.*)

APPENDIX TO CLASS VIII.

The trial of manual fire-engines took place on the 17th of June, commencing at eight o'clock in the morning, and lasting until six o'clock in the evening. By permission of his Royal Highness the Duke of Cambridge a convenient space of ground was marked out and railed off on the south side of the Serpentine in Hyde Park; posts were erected, holes for suction were dug, and handrails, spars, water targets, gauged tanks, blocks, halliards, and other gear were provided. Working lists were prepared beforehand to facilitate and methodize the entries of particulars, and a strong party of officers and firemen of the London Fire Brigade attended during the trials, and afforded skilled assistance to all who required it. Two hundred men of the Guards were present, and worked the manual fire-engines, and a party of police did equally good service in keeping order during the day.

Owing to the extreme clearness of the atmosphere, and the almost total absence of wind, the day selected for the trial of manual fire-engines proved in the highest degree favourable for the purpose. The barometer stood at 29·87 inches.

On the day subsequent to the trial the Committee assembled for the purpose of making awards according to the rules laid down at their first meeting, and after mature deliberation, it was resolved to make the following awards, which they beg to recommend for confirmation by Her Majesty's Commissioners:—

Names of Makers.	Description of Fire Engine.	Award.	Remarks.
Fowke	Manual ...	Medal ..	As inventor—engine well adapted for military purposes.
Kurtz	Manual	Hon. Men.	Compactness, simplicity, and good performance.
Lee	Steam	Medal ..	Ingenuity of design, and good workmanship.
Letestu	Manual ...	Medal ..	Excellence of construction, durability, and good workmnship.
Merryweather (Decorated by Casentini) ...	Manual	Medal ..	Improvements in design, good workmanship, & performance.
Roberts	Manual ...	Medal ..	Ingenuity of design.
Shand and Mason	Manual	Medal ..	Good workmanship and excellent performance.

Summary.

	English.	Foreign.	Total.
No. of engines in the building	37	6	43
No. of makers of engines . .	10	5	15
No. of engines offered for trial	15	3	18
No. of medals awarded . . .	4	2	6
No. of honourable mentions .	—	1	1

Although no further awards could be made, the Committee next proceeded to take the necessary steps for trying the steam fire-engines on the 1st of July, and, as before, invited the engine builders to a preliminary meeting, that they might receive full information as to the rules and regulations to be observed.

In compliance with this invitation, the following engine-makers attended a meeting on the 28th of June, viz.:—

Mr. Lee, of the firm of Lee and Larned, Novelty Ironworks, New York.
Messrs. Merryweather and Son.
Messrs. Shand and Mason.

Mr. Lee declined to produce his steam fire-engine for trial, alleging various reasons for so doing, and though strongly urged, persisted in his resolution, and declined the contest.

Messrs. Merryweather and Son expressed themselves ready to produce their steam fire-engine on the appointed day.

Messrs. Shand and Mason informed the Committee that the engine which they had intended to work would not be ready owing to an accident, but requested permission to produce for trial two steam-engines made by them for the London Fire-Engine Establishment, although they were not in the Exhibition. All the arrangements having been made for trying several engines together, the Committee granted this request, as otherwise only one engine would have been present, and a complete table of results could therefore not have been obtained.

The Committee assembled in the appointed place at eight o'clock on the morning of the 1st of July, and found three engines present, viz., one of Messrs. Merryweather and Son and two of Messrs. Shand and Mason.

After the Committee had examined the boilers and machinery generally, the engine-makers filled their respective boilers with cold water from the river, and fires having been laid, the three were lighted at the same moment, and the makers were ordered to commence working into a tank at sixty feet distance as soon as they had attained a steam-pressure of 100 lbs. to the square inch.

Messrs. Merryweather's engine attained the pressure named in 12 minutes 10 seconds, Messrs. Shand and Mason's large engine in 18 minutes 30 seconds, the small engine in about 30 minutes, some mismanagement having occurred which compelled them to draw the fire in the latter and light it a second time. Messrs. Merryweather's engine commenced working as arranged when the steam-gauge indicated a pressure of 100 lbs., and was 2 minutes and 50 seconds at work before water passed through the nose-pipe. Notwithstanding this very serious defect, this engine had poured 500 gallons of water into a tank 60 feet distant in 17 minutes and 15 seconds from the time at which the fire was lighted. After the difficulty of drawing the water had been surmounted, this engine worked well and threw an admirable jet, losing 15 lbs. steam-pressure during the first trial. After three trials this engine became disabled; it was, however, repaired on the ground in about an hour and a half, and resumed work at the ninth trial, continuing to work well until the thirteenth, when it became again disabled, and was withdrawn by the maker, to the great regret of the Committee, who were thus left to continue the experiments with only two engines, both made by one firm.

Messrs. Shand and Mason's large engine was 18 minutes 30 seconds getting up steam to 100 lbs., and when started drew water instantly, losing during the first trial 5 lbs. of steam-pressure.

This engine was severely tested, and worked without accident throughout the day, the seventeenth trial lasting no less than 63 minutes, during which the steam and water were both kept to a pressure of 90 lbs. on the square inch throughout, working through a 1⅛-inch nose-pipe.

At the eighteenth and last trial this engine threw a good vertical jet.

Messrs. Shand and Mason's small engine did not raise the steam to 100 lbs. in less than 30 minutes, owing, of course, partly to the mismanagement already mentioned, and partly to the nature of the boiler and fire-box, which, according to the makers' account, are not adapted for raising steam in the shortest possible time. After the engine got to work the steam-pressure was well sustained, and the engine continued working the entire day without accident, concluding in the evening by throwing a good vertical jet.

During the time occupied by the trials the direction of the wind was W.N.W. to W. by N., pressure 2½ to 4½ lbs. on the square foot. The barometer stood at 29·07 inches.

Summary.

On the whole the Committee find as follows:—

Messrs. Merryweather and Son have produced, at a price of £700, a steam fire-engine, weighing, according to the makers' account, 65 cwt., with jets and lamp, but without water, coal, suction-

pipes, hose, or other gear, and capable, if no accidents occur, of throwing in an available stream the following average quantities of water per minute :—

Distance.	Angle.	Quantity.
61 feet.	10 dg.	230 gallons.
85 ,,	21 ,,	124 gallons.

Messrs. Shand and Mason have produced an engine, at a cost of £650, weighing, according to their statement, 55 cwt., with jets and lamps, but without water, coals, suction-pipes, hose, or other gear, and capable of throwing in an available stream the following average quantities of water per minute :—

Distance.	Angle.	Quantity.
61 feet.	10 dg.	250 gallons.
63 ,,	18 ,,	165 ,,
82 ,,	14 ,,	172 ,,
85 ,,	21 ,,	137 ,,
102 ,,	11 ,,	94 ,,
104 ,,	17 ,,	19 ,,

Messrs. Shand and Mason have also produced, at a price of £370, an engine which, under the same conditions, weighs 35 cwt., and is capable of throwing in an available stream the following average quantities per minute :—

Distance.	Angle.	Quantity.
61 feet.	10 dg.	142 gallons.
63 ,,	18 ,,	133 ,,
82 ,,	14 ,,	56 ,,
85 ,,	21 ,,	27 ,,

The best performance during the five trials from which this last average was taken being forty-six gallons, and the lowest five gallons per minute.

At greater distances, in consequence of the wind, this engine could not deliver a stream, but continued working without accident throughout the day, and concluded in the evening by throwing a good vertical jet.

It is hardly within the province of this Committee to suggest improvements, or to do more than comment on what is actually performed ; but as the making of steam fire-engines is still in its infancy in this country, they consider it important, before concluding their labours, to place on record the following remarks, which may be found of service :—

The results of these trials show, that although something has been done towards making a really serviceable steam fire-engine, still much yet remains to be accomplished. These results show that a decided advantage is obtained in working fire-engines by steam, as compared with manual power, but there appears on the part of all the makers a decided tendency to run their pumps too fast. The Committee would also draw attention to improvements which may be made in many mechanical arrangements, viz., in the size of the suction-pipes, the supply chambers, and the valves, so as to give the greatest facility for feeding the pumps and preventing the return of the water.

Sutherland, *Chairman.*
E. M. Shaw, *Hon Sec.*

PREVENTION OF RAILWAY ACCIDENTS.

The following paper, by Mr. J. Sewell, Assoc. Inst. C.E., was read in Section G at the last meeting of the British Association :—

This is a subject of great importance, both to the travelling community and the railway interest, yet, in my opinion, it is one that admits of a solution with benefit to both parties.

Through your goodness, some years ago I was enabled to bring under the notice of the Association a paper upon the causes of boiler explosions, fracture of axles, and advantages of thick-edge boiler-plates, &c., which I believe has been useful, and I trust that my present suggestion, of a simple yet effective plan to obviate most of the railway accidents that occur, will likewise prove of utility.

The primary cause of most of the serious railway accidents is, that railway companies are not liable either for over-loading their engines or for not keeping time at all the stations. It only requires, in my opinion, to attach suitable penalties for both over-loading engines and for not keeping time, to ensure greater safety to the public, and better dividends to the shareholders. On many lines trains are more numerous than there is any need for, since every district has a regular traffic; beyond which, it requires stimulants to temporarily increase it, which stimulants, judiciously employed, do good, but, when used in excess, are both costly and dangerous, as train after train follow each other, some stopping at one station, and some at another station, and some, as express trains, at very few stations, where one train would suffice. A few accidents arise from gross neglect of signal duty, defects of the road, and breaking down of plant, which are more or less strictly accidental, for the best mechanism may, and does fail. The human being likewise may, and does fail unexpectedly at times, especially during long sustained watchfulness, whether on railways or other duty. On railways both men and mechanism frequently fail through overwork, or through surprise, caused by irregularity of the trains, as, for instance, the Brighton Tunnel and Kentish-town catastrophes, as well as many others.

Railway companies issue time bills for the guidance of their servants and of the public, but plead non-liability to keep such time. The plea is passively allowed, for there is no one to enforce time being kept; so that few trains keep time exactly at all the stations they pass, yet no effective notice is taken of this breach of contract unless through an accident. Now, as the loss of time is mainly due to irregularity in starting trains, and to over-loaded locomotives being unable to keep the specified time, it is evident that punctuality in starting trains, proper loads, and well kept time at all stations would effect a most advantageous improvement upon the present state of these matters.

It is commonly supposed that the steam horse possesses such unlimited power that a carriage or two more or less makes little or no difference to running the given distance in the given time, but this is a popular error which lies at the root of all the mischief.

The power of the steam horse is proportionably as easily overlooked, as is that of the coach or race horse, with this difference against the steam horse—namely, that he has to contend against all the contingencies of slippery rails, inclines, retarding winds, delays at stations (often due to travellers themselves), yet is popularly expected to run the distance in the given time, whether heavily or lightly loaded, whether stormy, slippery, or calm.

Now when the race horse runs against time, the weight is fixed for distance, time, and other circumstances. No one would dream of overweighting a race-horse, and then running him against the time for the lightest racing weight, yet this is the practice of railways, whereby irregularity is the result. Nature limits the power of the race-horse, and, in order to save fuel, mechanism is used to limit the power of the steam-horse, hence delays take place and risks are incurred in order to save a little fuel. This mechanism, as is well known, cuts off the steam from the cylinder some time before the power has reached the end of the stroke, varying from one-fourth to three-fourths of the length of the cylinder, so that the *real* and the *nominal* power may and do differ widely. If, therefore, an engine, having its power thus limited to take eight or ten carriages in the given time, has to take ten or twelve carriages, it follows that such overloading will cause loss of time.

But, as travellers do not know the power of a locomotive by looking at it, nor clearly understand the dangers they run on a crowded line by its being over-loaded, it becomes, I think, the duty of the Government to step in and ask for power to license each locomotive for a certain duty, and to enforce regularity of time at all stations, as essential to public safety.

It has been found necessary to licence steam-boats and common road vehicles to carry a given number of passengers only, and, in like manner, it has now become requisite, for public safety, to licence each locomotive to draw a definite number of vehicles, whether for passengers or for merchandise, and to place that licence conspicuously on each engine. Passengers generally take care that carriages are not over-crowded, and would equally take care that locomotives were not over-loaded, if they only knew the right road by referring to a licence plate on each engine. If it is necessary, for pecuniary reasons alone, that arrangements between two companies, or between the Post-office, and companies should limit the loads as they do, it is undoubtedly necessary, on the ground of safety between the railways and the public, to limit the loads to the real power of the engines.

The Board of Trade could easily carry out the required duty by means of qualified inspectors, with power to periodically alter, renew, or withdraw licenses, as the working state of each steam horse might warrant from time to time.

As such a step would probably require either an increase of locomotive power, or a decrerse of speed to work the same traffic, it would prove to that extent that the present engine-power was deficient for safe working. It is the over-loading of engines and uncertainty of time that renders excursion trains more dangerous than others, but that is no valid reason why excursion trains should be discontinued. In fact, there is no more need to deprive excursionists of their healthy, cheering trips, which contribute to recruit both their mental and bodily vigour, and railway exchequers, than there is to deprive society of food or wine, because both are occasionally abused.

Since excursion trains are a mine of wealth to a railway company, and a mine of health to the community, instead, therefore, of prohibiting them, as is too often suggested, they should be extended, as they may be without any such risk to them or to other trains as they have hitherto had to encounter. Substitute well-kept time for the present ill-kept time—licensed engines for unlicensed ones, and trains may run more frequently, and more safely than at present.

Under the present non-liability system, it speaks highly for the general vigilance of railway officials that so few accidents occur, and such an alteration as the one now proposed would be a great relief to them. The traffic on several railways now resembles that on an over-crowded street, where great difference in speeds cannot be allowed with safety; and as in crowded streets the extreme speed of the horse is dangerous, and at a moderate speed an enormous traffic can be carried on safely (along London-bridge, for instance, where there is five times the traffic of any railway), so in like manner on railways extreme speeds should be reduced to moderate ones, regularity be substituted for irregularity, whereby both safety and economy will result.

It is an axiom, I may say, that extreme speeds entail extreme costs, besides risks, for on railways as on roads or streets, costs increase in a greater ratio than velocities, so that high speeds and higher costs are synonymous and convertible terms. Limited loads and kept time duly enforced appear to me to be simple remedies for the existing dangers, which would alike contribute to the public safety and increased profits to railways.

UNSINKABLE SHIPS.

By Charles Atherton, late Chief Engineer in Woolwich Dockyard.

The following paper was read in Section G., at the Cambridge meeting of the British Association :—

Competitive rivalry in the arts of naval construction and ordnance destruction, as applied to maritime warfare, having now, as appears by recent demonstrations at Shoeburyness, reached a condition of experimental speculation prospectively of an unlimited character; and as the consideration of this subject essentially embraces the question of the capability of an invulnerably-armoured ship to carry armament with reference to the size of the ship itself, it is presumed that a paper thus involving the details of naval ar-

chitectural construction may be appropriately brought forward and discussed in the Mechanical Section of the British Association for the Advancement of Science.

The object of this communication is not to discuss the question, whether, by an unlimited expenditure, ships can be made invulnerable to the assaults of all present and future ordnance, nor is it intended to damp the ardour with which peace must be upheld by the moral effect of preparation for any adverse eventuality by our practically adopting, for the time being, in common with other nations, the recognized principle of "invulnerability." My object on the present occasion is simply to bring forward the question, whether the principle of "unsinkability," as based on the average specific gravity of the materials of which a ship may be constructed and loaded being less than the specific gravity of water, and as distinguished from "invulnerability" as dependent on armour plating, may not be advantageously introduced as supplementary to our present system of naval construction.

This subject has for some years engaged my attention, and in anticipation not only of the now-realized efficacy of direct fire, but also in anticipation of a totally new era of mortar practice not yet entered upon, whereby the decks of vessels may undoubtedly be assailed by the descent upon them of a huge weight (say 10 tons), projected to a great height (say 300 feet) at short range (say 100 yards), thereby attaining precision of descent, and falling almost vertically on the deck, and passing out through the bottom of an adjacent ship. Anticipating such results, I have already, by various publications, and officially in my late capacity as Chief Engineer of Woolwich Dockyard, directed attention to the principle of "unsinkable ships," as a means of obviating the fatal effects at sea of such devices. Mr. Atherton then read a letter of his which appeared in the *Times* on the 10th of January, 1859. It was as follows:—

Sir,—Many suggestions have of late been brought before the public on the construction of gunboats, mortar boats, and floating batteries, with a view to make them invulnerable; and I now beg to add my views on that subject. Why not make the floating body for such special services, up to the line of its load displacement, a solid mass of material of such specific gravity lighter than water that it shall not sink, however much it may be perforated by shot? It appears to me that a solid combination might be made of cork shavings, light wood sawdust, rush stems, cotton waste, flocks, hemp, and other light material, which by the aid of a solution of gutta percha, or other chemical process, would form a solidifying mass, so tough that it could not be knocked to pieces by shot, and so light that it would be only one-half the specific gravity of water, and therefore unsinkable, however perforated by shot, and capable of carrying armament and naval equipment to the extent of nearly one-half the weight of its own displacement in tons. Such vessels of light draught accompanying fleets of war as tenders to line-of-battle ships, whence they might be manned and stored as occasion might require, would, I submit, form a useful auxiliary available for shore service, or for attacking land batteries, which deep draught ships of the line cannot approach, and would be sunk if they could.

I may observe that this idea was first broached by me two years since as being applicable to the construction of vessels for carrying treasure. They might be wrecked ashore, but the treasure would be recoverable.

In respect to the practical carrying out of the general principle of "unsinkability," announced in the foregoing letter, I beg further to explain that I do not anticipate depriving war of the glory and honour which can only be purchased by blood. Without the sacrifice of blood in war, the naval and military calling would be ignominious, and the national spirit would become degenerate. No, let ordnance do its best. I would, however, seek in the construction of "unsinkable ships" that the life of a man may not be sacrificed by an ounce of lead, and that the whole crew of a ship may not be simultaneously drowned through the effective application of a single shot, or the descent of a single thunderbolt down through the deck and bottom of the ship, or by the lateral concussion of a hostile ram. With these views I always anticipated that the principle of "unsinkability" would, if adopted, be carried out, not exclusively by making the ship solid up to her load line, but on various plans of arranging and disposing of the buoyant material according to the special requirements of the service contemplated; for example, a treasure ship built for being laden with specially valuable goods may, if so preferred, be a mass of buoyant material up to its load line. But a steam-ship may be constructed with its engine-room below the level of the load line; into this the water may possibly get access, but the ship when thus water-logged would be saved from going to the bottom by a sufficiency of buoyant material being constructively disposed of in various parts of the ship, such, for instance, as the hull and decks above the load water line being composed of as great a mass of material as is equivalent to the entire capacity of hold in space left vacant below the load water line.

Of course the efficacy of this system would be entirely dependent on the degree in which the specific gravity of the buoyant material may be less than the specific gravity of water. Various communications have already been made to me announcing the discovery of natural substances and artificial compounds not exceeding half the specific gravity of water, and apparently suitable for being used as a buoyant material in the construction of unsinkable ships on the principles thus set forth. The practical prosecution of the subject is obvious, and the details of arrangements manifestly so adequate to the special objects for which a ship may be intended, that I need not, on the present occasion, encumber this promulgation of my views by entering into details. I would merely further observe that the mass of buoyant material may be so selected and disposed of that it may contribute greatly to the strength of the ship. Of course, in the practical adoption of this principle, as compared with the ordinary construction of ships, there must be a sacrifice of capability, but when it is considered that the great mass of buoyant material may be distributed below the water line, and thus conduce to the stability of the ship instead of being above the water line and thus impairing the stability of the ship, as is necessarily the case with the armour plating of invulnerable ships; and, moreover, when it is considered that the principle of unsinkability is applicable to vessels of small size, whilst invulnerability by iron armour plating can only be carried out with vessels of enormous magnitude, it may be confidently anticipated that the principle of unsinkability by the agency of buoyant materials, as distinguished from the principle of invulnerability by the agency of armour plating, is worthy of attention for mercantile purposes, especially in time of war, and as a supplementary adjunct for co-operating with ships of war in shoal waters where armoured ships, by reason of their necessarily great draft, cannot operate. In prosecuting the operations of war, ordinary ships, defended by unsinkable ships or otherwise kept out of harm's way, would be available as barracks, hospitals, and store ships for their accompanying fleet of unsinkable ships, of which the stowage for stores may be deficient.

KAMPTULICON.

So called from its flexible character, is designed to supersede the ordinary floor-cloth. Its chief recommendations are great flexibility, softness, imperviousness to damp and dust, great warmth (owing to its non-abstraction of caloric from the feet), noiselessness, and extreme durability. Its natural colour is not pleasing to the eye, but it is capable of being ornamented with any design, and with every variety of colour, so as to resemble encaustic tiles, tesselated pavement, or the best styles of floor-cloth. It is composed of cork and india-rubber, chiefly that obtained from the East Indies, and the invention is claimed for a Mr. Fanshawe, who made the first kamptulicon composition in the square shot tower near Waterloo-bridge, where he ground the cork in an old common coffee-mill. A patent was, however, granted to Elijah Galloway in 1843.

Kamptulicon is manufactured in London by Gough and Boyce, 12, Bush-lane, Cannon-street; Trestrail and Co., 20, Walbrook; and Taylor, Harry, and Co., Huggin-lane, Cheapside.

The buildings for the manufacture of kamptulicon ordinarily consist of one large room, with several ante-rooms attached, for the purpose of measuring and cutting, blocking or painting, drying and storing.

The first thing that arrests a visitor's attention is an immense quantity of cork shavings, the refuse of cork-cutting establishments. Kamptulicon has given a value to this refuse, which it did not possess when it was only employed for the purpose of stuffing fendoffs, &c. The cork is first thoroughly cleansed from dirt and other foreign substances. It is then placed in a machine, which cuts it up into very small chips; these are then submitted to the grinding action of two large millstones, worked in the ordinary manner, until the chips are completely pulverized and reduced to what may be called an extremely fine cork dust. The only other substance entering into the composition of kamptulicon is india-rubber; a quantity of this is placed in a hollow cylinder, in which an axle armed with strong teeth is made to revolve rapidly, the cylinder being heated by the admission of steam into a surrounding box or chamber. The machine itself is very properly termed a *masticator*, and in a short time reduces the rubber to a kind of resinous pulp, having the consistency of baker's dough. When sufficiently masticated the mass is removed from the masticator and placed upon a table, at one end of which is a pair of powerful rollers. The mass is sprinkled with the cork dust and passed between these rollers which are likewise heated by the admission of steam. Each time it passes through the rollers an additional quantity of cork dust is applied until the mass of rubber is completely permeated with it, and becomes an amalgam of rubber and cork dust; this we may term the kneading process, for the whole manufacture is only a repetition on a large scale, and by means of powerful machinery, of what is done by the pastry-cook with other materials in the manufacture of puff-pastry. When a sufficient quantity of cork is incorporated with the rubber (and this is the delicate point in the manufacture) the mass is subjected to what may be termed the laminating process. For this purpose it is taken to another table, which is of the length and width which the piece of kamptulicon is required to assume. It is then passed through a pair of rollers (likewise heated by steam) of the exact width intended for the piece; the space between these rollers is regulated by a screw, which is of such power that it is possible by its action to bring to a standstill a high-pressure steam-engine of 45 horse-power. Through these rollers the mass is passed again and again, rolled out into a thin layer, then folded over and rolled again, until the cork and rubber are completely amalgamated, and a vast number of thin layers have been formed, all bound inseparably together by the nature of the materials themselves. The proper length of the required thickness being secured, it is taken to an adjoining apartment and laid with others upon a long bench or table, where it remains several days or weeks to become thoroughly seasoned. If intended to receive a design, it is next removed into the painter's room, where, by means of blocks, it is painted according to the style intended, the paint is allowed to dry and harden, and the kamptulicon is then ready for service.

In addition to those already named, kamptulicon certainly possesses some very marked advantages over the ordinary floor-cloth. It can be joined together so neatly as to defy detection except upon the minutest investigation, so that although it is not found advantageous to make it in pieces exceeding 35 or 40 feet in length, and 4 or 5 feet in width, the largest area could be covered with it, and present the appearance of one single piece. This is done in the following manner:—The two edges are brought together with great exactness; they are then moistened with a small quantity of india-rubber solution;

the under surface of each length at the proposed joint is slightly coated with the same solution, and a narrow strip of cotton, linen, or fine canvas being placed along the proposed seam, the two edges are brought closely together. In a very short space of time the appearance and strength of one piece is secured. Width after width might thus be added *ad infinitum*.

Another advantage of the kamptulicon, being so easily joined, is that a border of any design may be attached, no matter how small or numerous the recesses of the room or hall in which it is proposed to lay it down. This is done by the manufacture of narrow strips for borders, which are stamped with the required design and colors, and joined, as already stated, to the centre piece. It would be impracticable to do this in the case of ordinary floor-cloth, as the exact form of the area to be covered would be first required, and then the cloth to be painted with the required border before the pattern for the centre was imparted to it. With this border kamptulicon presents a very pretty and unique appearance, and is well adapted for bath-rooms, halls, small rooms, or offices. For bath-rooms we consider it the *ne plus ultra* of anything yet produced. Ordinary floor-cloth is objectionable, as although it is impervious to water so long as the painted surface remains intact, it invariably strikes cold to the feet, which is both unpleasant and dangerous. Woollen carpets, again, become saturated and thus keep the atmosphere of the room damp, and themselves soon decay by being constantly moist. Owing to its warmth and extreme durability (we have seen some that after fourteen years' hard use bore scarcely any signs of being worn) it is admirably suited for nurseries; the ordinary floor-cloth is too cold, and carpeting is costly and dusty for rooms occupied by a family of young children. For public and private offices, assembly-rooms, churches, and chapels, where both warmth and quiet are indispensable, kamptulicon is an excellent, and in the long run, a cheap material. And we can only hope that the rising price of india-rubber will not stop the production of this useful article.

We were informed of a (to us) novel application of kamptulicon in the Royal stables at Windsor, and other places. By planking or paving the stable with it, the stable is not only kept warm, dry, and clean, but the usual straw bedding can be dispensed with, and by using it for partitions between the stalls, horses are less liable to injure themselves by kicking against it, and inasmuch as the noise occasioned by kicking against the wooden partition is often the cause of a horse becoming a confirmed kicker, the use of kamptulicon, which is noiseless, will tend to prevent this evil, and has been known even to cure horses of the habit.—*Building News*.

COURTAULD'S IMPROVEMENTS IN POWER LOOMS.—(*See p.* 278.)

This invention, patented by Mr. J. M. Courtauld, of Braintree, Essex, consists in the introduction into the web or fabric in course of manufacture of a slide, lever, or other mechanical agent connected with the gear by which the loom is thrown in and out of work, and made to act when no shoot is laid in, in such manner as to throw the loom out of work.

Fig. 1 of the above engravings is a longitudinal section, and Fig. 2 an end view of the apparatus; Fig. 3 is a plan of the underside thereof. *a* is a flat plate or table smooth on both its upper and under surfaces; *b* is a plate secured at one end to the under side of the table by a nut and screws *c c*, in such a manner as to give it a tendency to spring against the under side of the table *a*. This springing action may be produced by making a spring in the plate itself, or by the employment of a separate spring; *d* is a projection on this plate, to which the outer end of a light spring *e* is secured; *f* is a bolt formed with slots, to allow of its moving to and fro upon cross-headed screws *g*, whereby it is connected to the under side of the plate *b*; *h* is a stud on the back end of the bolt *f*, against which the free end of the spring *e* exerts its pressure; *i* is a carrier or bar armed with pins *k*, *k*, screwed to the outer end and upper surface of the bolt *f*; *l* is a hook fixed on the under side of the bolt; *m*, *m*, are screws, which receive and act as stops to the outer end of the plate *b* when it descends, as presently explained; *n* is a drop lever, shown broken away at Fig. 3, pivotted at one end on the spindle *o*, held in the side frames of the apparatus, at its opposite end the lever is armed with and terminates in a solid inclined-headed catch *p*, at the rear end of the catch there is a slot in the lever to give passage to the hook *l*, so that the lever may fall, as hereafter explained; *q*, *q*, are flanges on the side frames of the apparatus, by which it is fixed through screws *r*, *r*, to the angle iron *s* forming part of the framing of the loom; *t* is the loom batten; *u* is the reed attached to the batten; and *v* is a lever, having its centre of vibration coincident with the centre of vibration of the batten.

The fabric as it is woven passes upon the table *a* in the direction from A to B. In Fig. 1 the reed is shewn close up to the woven quarter, the weft pins are introduced into the web of the fabric, the last shoot or thread laid in is on the outer side of them, and exerts sufficient pressure through them on the bolt *f* to overcome that of the spring *e*, and consequently prevents the bolt *f* being forced out when the reed recedes. As the batten recedes the weighted end of the lever *n* drops, and becoming engaged in the hook *l*, it pulls down the weft pins *k*, *k*, out of the fabric, and carries down with it the bolt *f* and the plate *b*, until the sides of this plate come in contact with the heads of the screws *m*, *m*, when further descent is prevented. In this position these parts remain until the batten comes up again On its return the batten, coming in contact with the inclined face of the catch, raises the drop lever, and allows of the springing up of the bolt *f* and plate *b*, and introduces the weft pins *k*, *k*, again in the web of the fabric just before the reed has brought up the next shoot. When the shoot is not laid in from a thread having become broken, or from the shuttle having given out all its thread, there being no pressure on the pins *k*, *k*, to overcome the power of the spring *e*, the bolt is forced outwards sufficiently far to prevent the hook *l* becoming engaged with the drop lever *n*, which then becoming entirely free at its weighted end falls low enough to catch on to the top of the lever *v*, which lever always vibrates with the battens, unless held by the catch on the drop lever, as just explained. Any suitable appliances, such as levers, cranks, pulleys, or otherwise may be connected with the lever *v*, in such manner that the loom would be thrown out of gear with the motive power upon the said lever *v* being arrested, but the arrangement the inventor adopts for the purpose is shewn at Fig. 4 and 5, in which *t* is the loom batten, *v* is the lever on which the drop lever *n* hooks when no shoot is laid in; this lever *v* is attached to the batten bar by a pivot joint at 4, just at the centre of vibration of the said batten bar. 1 is a pulley and frame attached to the loom batten; 2 is another pulley and frame attached to the batten bar; 3 is a stationary pulley and frame attached to the back framing of the loom; 5 is a sliding bar flattened and slotted at its uper end, as shown in Fig. 5. This bar slides through fixed guides near each end. 6 is a coiled spring of steel wire, its upper end is attached to the top guide of bar 5, and its lower end to the bar itself; 7 is a sliding bolt, one end of which passes through an eye, and is furnished with a pin which projects through the bent slot in the top of bar 5, the other end is supported by and passes through the end framing of the loom; 8 is part of the back framing of the loom, having projections, which form the guides for the bar 5 and the bolt 7, and also the support for pulley 3; 9 is a gut line, attached at one end to the lever *v*, and at the other end to the lower end of the bar 5, this line passes over the pulleys 1, 2, and 3, as shown. When the lever *v* is prevented by the drop lever *n* from going back with the batten *t*, the slide bar 5 is pulled down by the gut line 9, and by means of the bent slot in the upper end of this bar the bolt 7 is pushed forward, and acting on the usual band fork passes the driving band from the fast on to the loose pulley, and throws the loom out of work.

A NEW MARINE BOILER.*

INVENTED AND PATENTED BY DR. FILIPPO GRIMALDI.

The object of the present paper is to draw the attention of the section to a new kind of steam boiler, adapted both for stationary and marine purposes, but more particularly to point out its advantages in the latter case, and especially when employed for generating high-pressure steam; or in iron-plated ships of war where saving of weight and space are of the utmost importance. The peculiarity of the arrangement referred to is that of making the boiler continually rotate on its axis over the furnace while at work. This involves necessarily a complete change in the shape of the boiler, as also in the mode of feeding it, and in the arrangements for the exit of the steam.

The advantages of the arrangement as regards rapid generation of steam, result from the fact that, water being an indifferent conductor of heat, this is disseminated almost entirely by a mechanical mixture of its particles, this mixture being very materially increased by the constant dipping and rising of the tubes which are dispersed throughout the boiler. Again, it is well known that where steam is generated in contact with a heating surface, if that surface be stationary, there is considerable difficulty in the steam freeing itself from such surface, this difficulty being apparently entirely removed by slowly moving the surface so as to bring it successively under new portions of water, the surface being as if it were swept of the globules of steam which have accumulated upon it.

In the rotating boiler this continual successing of the surfaces applies both to the shell of the boiler and to the tubes, their rotation being very slow, while the water is practically stationary.

The rotating boiler necessarily assumes the cylindrical shape, no other form being so suitable. It is thus specially adapted for the generation of high-pressure steam, and consequently is well worthy the attention of those who have, for some years past, been aiming at the construction of high-pressure marine boilers, their efforts, however, appearing to have failed, chiefly from such boilers being made to assume a rectangular shape; the ordinary amount of heating surface, if attempted to be obtained in a common cylindrical tubular boiler, involving considerable space, which can be ill afforded in steam vessels.

Without attempting to fix what precise extent of revolving heating surface will in practice be found equivalent to that ordinarily allowed in marine boilers, it may here be stated that from the experience already had, about one-fifth of the surface appears sufficient—9 square feet of *horizontal* surface, or 15 square feet of total surface, being usually calculated as sufficient for evaporating a cubic foot of water per hour, and 8 square feet having done this with the boiler revolving. Of course this amount of surface in both cases supposes the surfaces clean, from 20 to 30 ft. being frequently given to each horse-power in marine boilers as generally made. The rotating boiler (shown in the diagrams exhibited to the section) is cylindrical, with flat ends, and nearly filled with 3-inch tubes; trunnions are constructed at each end, through one of which the feed-pipe passes, and through the other the steam-pipe, which radiates from the centre to the circumference between the tubes, the steam entering at the highest point of the boiler, or nearly so, and thus taking no water with it; the upper tubes, or those passing through the steam space, most effectually super-heating the steam, and preventing priming. The safety valves of these boilers

* Read before the mechanical section of the British Association at Cambridge.

GRIMALDI'S NEW MARINE BOILER.

FIG. 1.

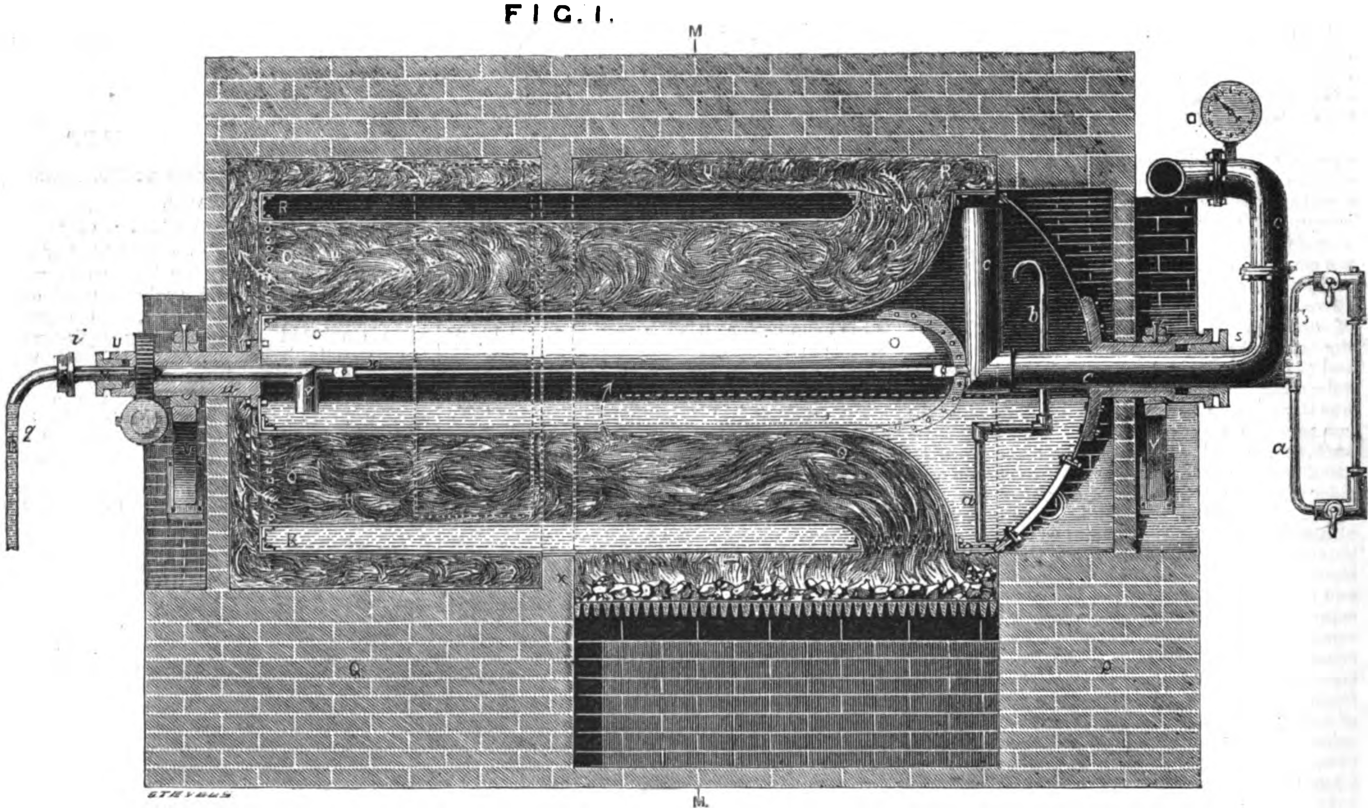

FIG. 2.

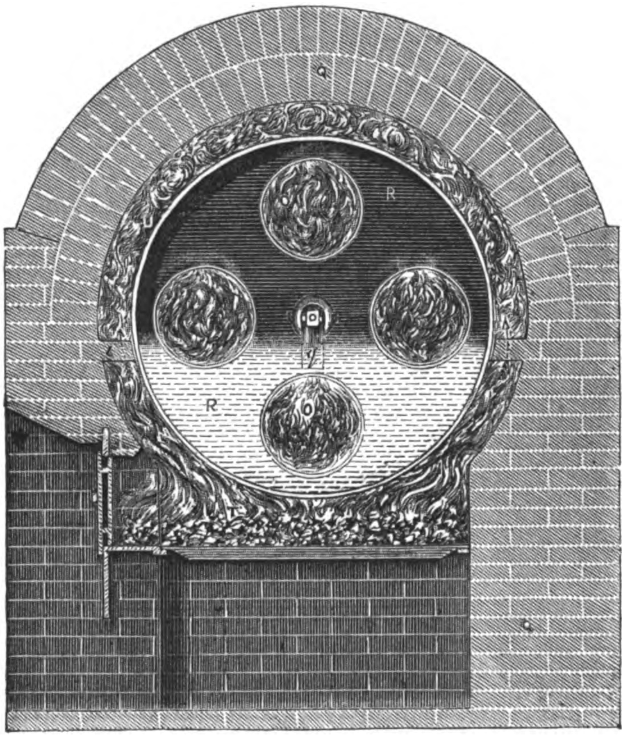

are fitted to the stationary steam pipe, and the steam and water gauges are conveniently arranged in the manner shown. The boiler is kept rotating at the rate of $1\frac{1}{4}$ to $1\frac{1}{2}$ revolution per minute, by means of suitable connection with the screw-shaft, or by a separate engine, which may also serve as a donkey for feeding the boiler and other purposes.

The whole boiler is enclosed in a brick-lined casing, or in a double iron casing filled with water, a few inches larger than the boiler, so as to give a flue space all around it. Every part of the shell of the boiler in its turn passes over the furnace which is placed beneath it, the entire boiler being thus rendered available as heating surface. This, it should be explained, is one of the reasons why so small a boiler as the one experimented upon, was found capable of generating so large a quantity of steam; for, taking the efficiency of moving surface as only equal to double that of stationary surface, the entire shell of the boiler—top, bottom, sides, and ends, becomes heating surface, and that of the best kind, being horizontal, and brought immediately over the furnace, which is usually made to extend under the entire bottom of the boiler.

In this arrangement the plates of the boiler can never become overheated, as however small the quantity of water in the boiler, the bottom is certain to be first covered, thus rendering explosion from this cause *almost impossible.*

It appears that the rotation of the shell and tubes of a boiler greatly retards, if does not entirely prevent, ordinary incrustation. The small experimental boiler now in the Exhibition, after being at work with very indifferent water for fourteen months, was examined at about six months' intervals, and found to be covered with a light dust on the inside, but to have no appearance of incrustations, although slight traces of this were found at those parts of the boiler which did not move, such as the feed-pipe, which is stationary inside the boiler. The singular manner in which many marine boilers have been affected, apparently by the action of acid formed in the greasy patches found on the sides of the boiler, and on the tubes, where surface-condensers are employed, has not been yet satisfactorily accounted for, but may partly be due to the scum floating on the water always being in contact with the same part of the boiler. It is more than probable that in the rotating boiler this evil will be entirely remedied, the whole surface of the shell being brought in contact with the scum, but for a very short time only as regards any one part of it. Experience is, however, wanting on this point.

As regards the employment of this class of boiler for ships of war, and especially for iron plated ones, it possesses two important advantages; first, it being a very low boiler, the largest size not extending 10 ft. in height, and secondly, its weight, with water and casing complete, not amounting to one-half that of ordinary marine boilers, even allowing the same heating surface, which, as has been stated, will probably be found to be three, or even four times more than necessary. Its size is also very greatly diminished, as will be seen from the following particulars:—

An ordinary marine-boiler, having about 1,400 feet of effective heating surface, occupies a space of 10 ft. 6 in. by 11 ft. 6 in., and is 16 ft. 6 in. high, weighing with water $31\frac{1}{2}$ tons. This gives about 51 lbs. per square foot of heating surface, and 1-10th of square foot of floor space occupied per square foot of heating surface. On the other hand, a revolving boiler having upwards of 1,600 ft. of heating surface occupies a space of 9 ft. 6 in. by 7ft. 4 in., and is 9 ft. 7 in. high, occupying thus only 1-25th of a square foot per square foot of heating surface, weighing with water 13 tons, equal to 18 lbs. per square foot of heating surface.

Thus, assuming for the moment that a square foot of heating surface is equally efficient both in the ordinary marine and the rotating boiler, it will be seen that the rotating one is less in every way, viz.:—

In weight about one-third.
In bulk about one-fourth.
In height about one-half.
In floor space about one-half.

With the revolving surface only doubly as effective as stationary surface, these advantages would be just doubled, and if experience in future justify the conclusions already arrived at, one-third of the whole amount would be the relative weight and space occupied respectively by a rotating boiler of equal power to a common marine one.

One word, in conclusion, as to consumption of fuel. On this point results of experience cannot be given, inasmuch as the boiler now in the Exhibition is too small to lead to enable conclusions to be formed. It is 18 in. in diameter only, and 18 in. long, but it has converted into superheated steam 7½ lbs. of water by the consumption of 1 lb. of coals. In larger boilers there can be no doubt that a good result will be obtained, owing, first, to the small quantity of water contained in the boiler, and consequently to the rapidity with which the steam is raised, and secondly, owing to the steam being in contact with one-half of the whole heating surface, thus leaving the boiler highly superheated.

The decrease in weight and size, and consequently diminished cost; freedom from excessive wear in any one or more of its parts, the wear being quite uniform; the strongest possible form and freedom from liability of explosion from this cause, as also from uniformity of wear and tear; simplicity in manufacture and repairing. Everything seems to recommend this boiler as a most suitable high-pressure one for steam-vessels.

In order to ascertain thoroughly what advantages can actually be realized in practice, a boiler of 30 nominal horse-power is now being constructed by Messrs. John Stewart and Son, of the Blackwall ironworks, and which, after being fully proved upon land, will be placed on board a vessel to be subjected to the ordinary usage of marine boilers.

The accompanying diagrams represent a flue-boiler of 23 nominal horse-power, exhibited at the International Exhibition, Western Annexe. It differs from marine boilers of the same principle, only for having 4 in. internal flues instead of 3 in. tubes on Dr. Grimaldi's plan, and exhibited by the inventor at the International Exhibition, Italian department, Western Annexe, No. 1,001. Fig. 1 is a longitudinal section taken through the centre of the boiler; Fig. 2 a transverse section taken at M. M. From the fire-grate T the fire passes over the surface of the boiler R, and through the interior of the four flue tubes o. o. The boiler is fitted with the fore and aft trunnions *s* and *u*, which turn in bearings; *q* is the feed-pipe, and *c* the steam-pipe. The feed-pipe is kept in its place by means of the cross and side bars *i* and *v*. The trunnion *u*, enclosing the combination of the feed-pipe *q*, is turned by a worm and screw or any other similar mechanism. The driving power required is very small, as the boiler makes but one revolution per minute; *a* is the water gauge, which acts like a syphon, *c* is the steam guage, *Q* is the masonry, *t* the furnace, *l l* are two sets of bricks preventing the flames from overheating the top of the boiler when not in motion.

The chief dimensions and particulars of the boiler exhibited by Dr. Grimaldi, are as under:—

Diameter of the boiler 4 ft., length 8 ft. 6 in., plate 7-16ths.

Diameter of flues 1 ft. 2 in., plate ⅜.

The boiler has been tested at a pressure of 200 pounds per square inch, and with safety stands a working pressure of 75 pounds per square inch.

This construction of boilers, unlike the Cornish ones, is adapted for the consumption of every kind of fuel, and is well suited for marine purposes.

CLEGG'S NEW PATENT WATER METER, WITH KRUNSCHRŒDER'S IMPROVEMENTS.

FIG. 1.

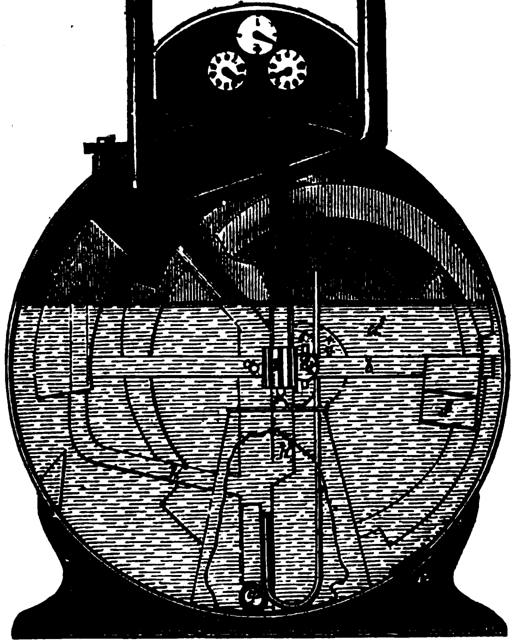

FIG. 2.

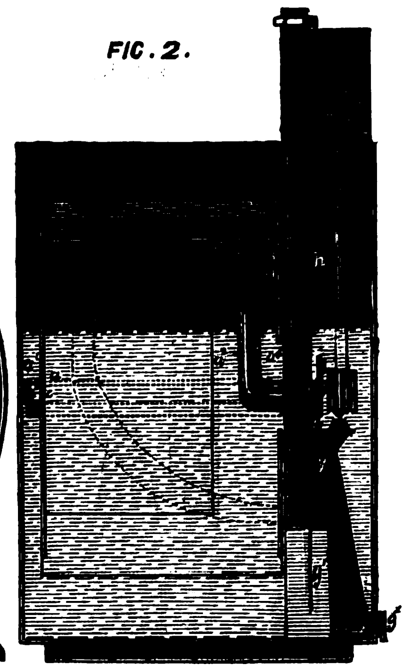


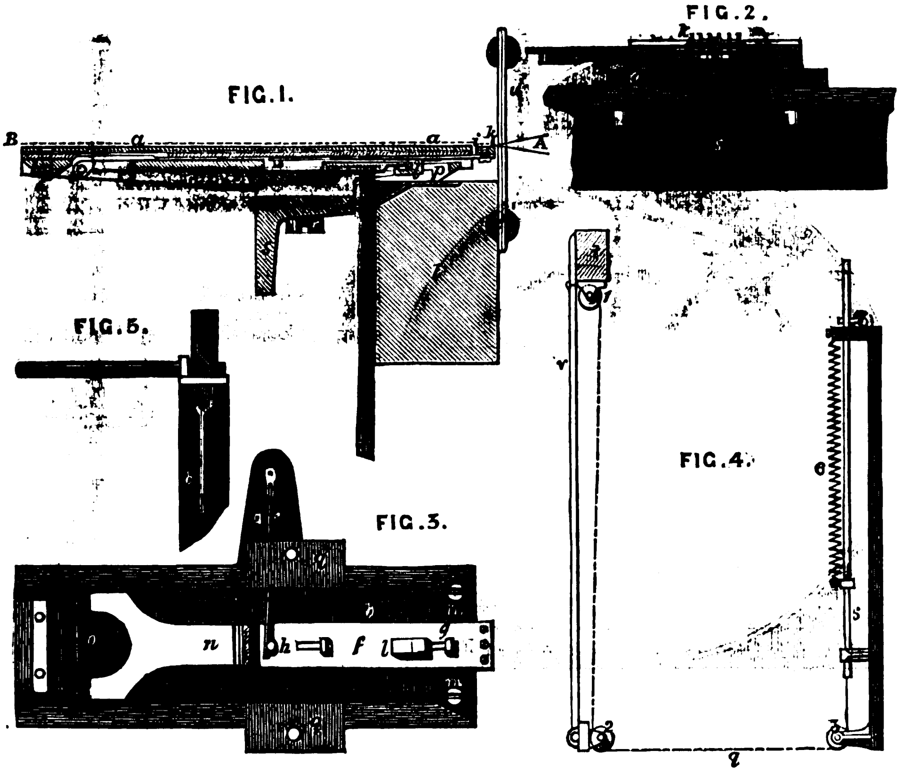
CLEGG'S NEW PATENT WATER METER, WITH KRUNSCHRŒDER'S IMPROVEMENTS.

THE above gas water meter is shown in the International Exhibition, No. 6,283, Section B, Class 31, being manufactured by the firm of Bischoff, Brown, and Co., of Langham Works, George-street, Great Portland-street, London, W., the successors to, and improvers on, the late Mr. Samuel Clegg's various patents in gas engineering. Mr. Samuel Clegg, as is well known, devoted his great abilities for nearly half a century to the improvement of gas apparatus, having taken out his first patent for a water meter in 1815. Having, in the mean time, tried various plans for dry meters, he at last, in 1858, two years before his death, returned to the improvement and perfecting of the water meter.

To effect this he found that the registrations required to be rendered independent of any variation of water level, caused either by evaporation, wilful abstractions, or an undue adding thereto of water. Mr. Clegg having died before he had fully carried out his ideas, the meter, as represented above, has formed the subject of a patent of a gentleman formerly in his employ, and now in that of Messrs. Bischoff, Brown, and Co.

Fig 1. shews a front view of this meter, some of the details being in section. Fig. 2 shews a transverse section. It consists essentially of a drum, or series of eccentric chambers placed round a central air-vessel, which permits it to rise and fall according to the height of water in the case; that of the friction on the bearings is thus removed, and the meter can be solidly constructed. When the meter is once adjusted, it maintains the same measuring capacity under any alteration of the water level or variation of pressure. The hollow central part of the drum is closed at the back end; it has also a cover at the front end, which has a central opening through it. This opening is, however, below the water-level, so that the central portion of the drum is enclosed gas-tight. In the central portion of the drum is a hollow float, between which and the front end of the drum there is a space, into which the gas is conducted by a branch on the supply pipe, which enters the opening in the centre of the front end of the drum. The axis *a* of the drum is fixed in the centre of the back end a^1 of the drum, and also in the centre of the front end a^2 of the float. By these means the measuring drum is fixed to and carried by the axis *a*. The front end a^3 of the drum is, as before stated, closed at all parts excepting at the central opening a^4, which is at all times below the water level in the meter, both interior and exterior of the drum. The back end of the axis *a* of the measuring drum is received into a bearing or hole in the frame *b*, which moves in fixed axes or necks, *c c*, one of which is fixed at the back end of the meter, and the other is fixed near the front of the meter above the waste water box hereafter described. The frame *b* thus acts as a lever frame, the axis *a* of the drum being received and supported by the frame *b* on one side of its axes, whilst on the other side of these axes the lever frame *b* is affixed to an inverted vessel *d*, which acts as a regulator. This regulating vessel is open at bottom, and close at the top as well as at the sides. The front end of the axis *a* of the drum passes through a slot or slit in the lever frame *b*, by which as the frame *b* moves on its axes the front end of the axis *a* of the drum is capable of being at times at a greater distance from the axis of motion of the frame *b* than at others; but the axis *a* of the drum is at all times kept correctly in position by a vertical slit or slot in the plate or frame *e* above the overflow vessel, which vessel is formed at the front end of the meter: *f* is a weight which is applied to the frame *b*, and is capable of being slid thereon, and of being fixed in any desired position. This weight is used to adjust the correct working of the regulating vessel and the measuring drum. The water level shown in figure 1 of the drawing is that when the frame *b* is horizontal or nearly so. The water line in the meter may at times be higher or lower than that which is shewn in the diagram, but never so low as to come below the upper part of the opening a^4 formed at the front end of the measuring drum, otherwise the gas would pass out through the opening a^4 into the case of the meter; *g* is the overflow vessel or waste water box, which is at the front end of the meter. This vessel is divided by a partition at g^1, as shown at Fig. 2. by which arrangement water will at all times be in one part of the overflow vessel up to the top of the partition g^1, which will cause the lower end of the gas supply pipe *h*, which is open, to be constantly closed or covered by the water in such manner as to prevent gas passing from the supply pipe *h* into the waste water box *g*. Any water which may overflow the partition g^1 can be run off by the plug-hole g^2 when desired. The gas supply pipe *h* enters the meter at the upper part, and at the front end of the meter the pipe *h* is bent, and, as before stated, enters into and descends to near the bottom of the overflow vessel *g*. The gas supply pipe *h* has two branches h^1 and h^2; the branch h^1 passes laterally till it comes under the front end of the inverted vessel or regulator, then the pipe ascends in an inclined direction, so as to come above the highest water level at the back end of the inverted vessel, leaving, however, a distance between the upper end of the pipe h^1 and

COURTAULD'S IMPROVEMENTS IN POWER LOOMS.—(*See page* 275.)



the inner surface of the back end of the inverted vessel, so that that vessel may rise and fall freely in the water without touching the upper end of the pipe h^1, where it comes above the water level within the inverted vessel or regulator. By this means it will be evident that the regulating vessel will at all times be filled with gas above the water level of the meter, and the rising of the regulating vessel will tend to depress the axis a and the measuring drum. The effect of this tendency to depress the axis of the drum is regulated by the position of the weight on the lever frame b, before mentioned. The effect of the branch pipe h^1 inclining from the front to the back end of the inverted vessel will be to prevent any gas being taken from the meter by tilting the meter backwards, as by so doing the water in the meter would descend down the pipe h^1. The supply of water to the meter is introduced through the pipe i, which is applied at the front end of the meter, as is also the case with the gas supply pipe h, and also the outlet pipe; and at the upper part or top of the inverted vessel or regulator d is applied a flexible surface valve or stop, which when it comes against the inner end of the outlet pipe j will stop the passage of gas out of the meter. The gas from the supply pipe passes to the measuring drum through the branch pipe h^2, which enters the opening a^4 in the front end of the drum, and rises to the height of the proper highest water level of the meter, so that it will be understood that this branch h^2 rises to a height somewhat less above the water than the branch h^1, which rises to a height somewhat above the highest water level in the meter. The water in the meter will be prevented standing above the top of the branch pipe h^2, as the water will, when it comes to the top of such branch h^2, flow down through into the overflow vessel; k is a worm or screw on the front end of the axis of the drum, which takes into and drives the long pinion l, which is on the axis m, by which the number of revolutions of the measuring drum is registered in the ordinary manner. The water is drawn off from the meter at the plug-hole n.

General C. F. James, the inventor of the "James projectile," has died from a wound received from the explosion of one of his shells.

DEFLECTIVE ARMOUR PLATES.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

Sir,—Will you permit me to remind your valuable correspondent, "Civilian," that in one of his early letters he stated that any mistake of his would be readily acknowledged. His calling the systems of Mr. Roberts and Mr. Westwood angulated, I boldly state is altogether wrong; neither of these gentlemen's inventions have any claim whatever to be so called. Mr. Westwood's specification (No. 1,420, A.D. 1860), thus describes his system:—"The surface of the plate is corrugated, indented, grooved, or channelled to a depth of not less than two inches." This, be it remembered, on a flat upright iron plate; it was scored just as a butcher scores a loin or leg of pork, and the only effect was, the 4½ in. plate was reduced in strength to one of 2½ in.

Mr. Robert's patent (No. 3,011, A.D. 1806), shows his iron plate surface, or side of the ship, in the form known to ladies as crimped up; he crimped up the side, in ten angular projections, 2 ft. from centre to centre of each, with dogs teeth of tempered steel at the points; his idea was that "the effect of shot or shell coming in contact with the dogs teeth would be to smash or splinter the missile."

Now neither of these systems are angulated, much less deflective: sunk corrugated lines on flat armour whether made oblique or horizontal, are sources of weakness; and as "Civilian" justly remarks, "present protruding points to be more readily shot away."

Mr. St. John Vincent Day's plan is in no way a counterpart of either of the systems: he adopted my section, elongating, instead of rounding it, taking my size, twenty feet for the height.

It is only in his 15th letter that "Civilian" first uses the word deflection; he then mentions the system as having proved to be a mistake, and informs us that Mr. Westwood and Mr. Roberts had targets made under that principle, which have been tested unsuccessfully. With all due deference to "Civilian," in appearance, he wishes to shelve all discussion on the deflective principle, by connecting it with two systems which have passed away, and which had no similitude whatever with it.

If flat upright iron plates for ships of war are to be ever made shot proof, their thickness must be measured in feet, not in inches; already plates of 8, 9, and 10 inches are talked of, although the "Warrior" is known to be a bad sea boat with an armour thickness of only 4½ inches.

"Civilian" has admitted, letter 17, that I am quite right as to the law of deflection. Now I beg to submit to his quiet consideration whether or not a target of twenty feet diameter in the form of a flat core, with a slightly curved lip, (the ancient arm bearing defence of Scotland) is not a far more sensible form to receive a heavy shot than a clumsey flat iron slab. He has always rightly made the fastenings and backing for armour plates matter of the greatest importance; the fastenings should be protected from impact of shot, while they should be capable of drawing the plates firmly to the backings; from both these points can be easily secured by conical shield armour. In fig. 8 of my specification drawing I show the fastening, (which, by the way, since its appearance has been twice patented by other parties). I made flanges by turning back the edges of the plates at right angles, and bolted them together, thus securing them from impact. The form of the shield allows the backing to be so securely pressed or forced against the inner surface of the plates, that should any portion of the latter be ripped or shot off, the backing would be pressed through the opening presenting a level surface.

I am, Sir, &c.,

34, Kensington-square, C. J. Richardson.
27th Oct., 1862.

DEEP-SEA CABLES.

Sir,—It is somewhat remarkable that all seamen who have hitherto ventured an opinion on the subject of deep-sea telegraph cables are unanimous in condemnation of the cumbrous iron sheathed cables hitherto in use, and join in recommending lightness, in so far as it is compatible with strength and durability.

The very interesting letter of Lieut. Davis, R.N., in your impression of the 17th inst., is an additional testimony to the soundness of the opinion long since formed by not a few thinking men who have made the subject their study, that the strength of such cables is in reality their weakness. The arguments used Mr. Davis are conclusive proofs thereof. And I dare say your readers have not forgotten the strain of playful satire with which Captain Selwyn treated those massive metal-mailed monsters, hitherto thought so desirable for submarine purpurposes, in his valuable paper on a new method of paying-out cables. One cannot peruse the evidence of the various seamen before the Government Committee without being struck with their unanimity on this point. There is the evidence of Admiral Fitzroy, for instance, at page 196 of the Blue Book, who cannot speak in too strong terms condemnatory of heavy iron cables. Is the evidence of men, so thoroughly competent to be correct judges as to the sort of cable most desirable for deep seas to be ignored? It seems to me that the very nature of their vocation eminently qualifies them to judge, and judge unerringly, on this matter, and, doubtless, so thought the Government Committee, else what is the meaning of the words relative thereto at page 35, Blue Book. None of the gentlemen referred to assume a knowledge they do not possess; they speak of the *outward* construction of the cable *and that only*; and do not venture on the debateable ground occupied by the electrician and ordinary telegraph engineer, nor have they any occasion to do so. It must be patent to every one that efficient protection of the core may be secured, without having recourse to that style of outward sheathing which is now the subject of animadversion. The position thus occupied is not unbecoming, and modest in the extreme, and is of itself a sufficient proof of their sincerity and competency, which under all circumstances is entitled to respect, nay, more, to adoption, since it is the result of years of matured experience.

Your correspondent may well be surprised that a second Atlantic cable should be projected on the same principle as the first. The true cause of the failure of the first cable was doubtless its great weight, although other causes contributed thereto which may or may not remain secrets; and it is hardly credible that the same company should entertain a second cable of a similar construction, especially as it must be of one unbroken length, which adds tenfold to the risk in submerging. If the cable could be laid in sections of 300 or 400

miles, the case would be different, and some justification would exist for persisting in giving the preference to a ponderous cable. As it is, however, seeing they will have none other than the direct route as before, and eschew the northern route utterly, we can only hope, and that confidently, that the good sense of the Government, and men of capital of this country, by looking shy on so wild a project, will by holding back the sinews of war prevent an additional half million being sunk uselessly in the depths of the Atlantic.

Yours obediently,

Walworth. S. TAYLOR.

PROPULSION OF VESSELS.

SIR,—Some time ago, you had frequently in your columns an advertisement of a new means of applying the force of steam for the propulsion of vessels. I refer to Mr. Parker's plan, which is, to send a jet of steam into a pipe which communicates with the sea at the stern of the boat, and which steam, in conjunction with air which goes in along with it, propels the boat. I have seen the plan at work in a 6 in. model, at the Crystal Palace, but this is on too small a scale. My object in writing is to ask if it would answer in a large vessel. I have a yacht with engine and screw in, to use in calms; but I find the screw to be a great drag when under sail, besides which the shaft lessens the head room in the after cabin. In Mr. Parker's plan there would be no drag; and by having the steam pipe low down, the loss of head room is not nearly so much. Of course, I do not think the plan *commercially* useful, but to preserve the sailing qualities of my boat, I should not objecct to burn the same coal per hour, and put up with less speed; I therefore beg to ask your opinion as to what speed I could get with 1 cwt. of coal per hour, supposing that, with my engine and screw, I now get eight statute miles? In Mr. Parker's plan, I should lose my blast from the exhaust steam which I now have.

October 28, 1862. X. Y. Z.

WOOD BACKING.

SIR,—Your correspondent, "Civilian," in last week's number of the MECHANICS' MAGAZINE, says, "Let it only be well understood that to project bolts made of hardened metal against iron plates is the same thing as to drive a punch through a boiler plate," and again, "the explosive force of gunpowder is the machine; the shot is the punch." He considers that the backing of tough wood in the "Warrior" is of little or no use, because a wooden plank would not be of any service in preventing a punch penetrating a boiler plate. Now although I am not of the "Warrior" party, I must beg to differ from this gentleman, for, in the instance of a shot and plate, the shot is propelled from the gun with a certain velocity, decreasing every moment after it leaves it; in the case of a punch and boiler plate the punch is moved by the machine with a uniform velocity all the time, and so if nothing has power to stop it altogether, it will go on and perform its work, whereas, in the former case, the shot having no power to propel it except its momentum, would certainly be decreased in velocity by the friction in passing through an iron plate some inches thick, and the wood, *if there be enough of it,* would finally stop it altogether.

Q. X.

HORIZONTAL-STEERAGE OF BALLOONS.

SIR,—In order to direct balloons *horizontally and at pleasure,* I propose fixing *wings* on each side of the car, (in perfect imitation of *bat's* wings) to be acted on by mechanical power in imitation of nature. The turning of a winch will give motion to a small wheel, that to another on the right and left, giving play to the two wings. The person who turns this winch is seated at the helm, guides at the same time a *fine spreading tale,* (as rudder) which may be moved with ease (as may the wings) in any direction, perpendicular, horizontal, or oblique. The wings to be formed of the finest and hardest steel, by allowing it with 1-300th part of *silver,* and covered with waterproofed crimson silk, of the strongest kind.

I am, Sir, yours faithfully,

JAMES BRUCE (late 33rd Regt.)

London, 27th October, 1862.

Gossip.

On Saturday last two additional lifeboats, on the plan of the National Lifeboat Institution, built for the Portuguese Government, had their harbour trial in the Regent's Canal Dock, Limehouse. They underwent most satisfactarily the usual testing of their qualities of self-righting, self-ejecting of water, and of stability. They will leave on board a steamer for the Peninsula. Six lifeboats, including the two in question, have been built within the last few months by the Messrs. Forrest, under the directions of Admiral Sir Gearge Sartorius, for the Portuguese Government. A lifeboat for the National Institution, intended for Drogheda, on the Irish coast, was also tried on Saturday, with an equally satisfactory result. She left London on Monday on board Messrs. Malcolmson's steamer for Dublin. During the past stormy week some of the lifeboats of the National Lifeboat Institution have, in addition to assisting several vessels into port, saved twenty-two shipwrecked sailors from different wrecks, who must otherwise in all human probability have perished. Within the last two years and a-half the lifeboats of the institution have saved nearly 800 sailors on various parts of our coast.

Messrs. Peel, Williams and Peel, Soho Foundry, Manchester, have completed the forging of the largest wrought-iron shaft ever made in that city. The shaft is 29 ft. 7 in. long, by diameters varying from 18½ in. to 22½ in., its weight being nearly 12 tons. It is to replace a cast-iron shaft which has broken in one of Messrs. Wren and Hopkinson's huge water wheels, now being repaired by that firm. The shaft is made from scrap iron, puddled in a ball furnace, and wrought into density and its present form by a belly-elve hammer, which is capable of striking a blow equal to a force of six tons, and yet can be so nicely regulated by a steam throttle valve as to give the lightest blow which may be required, while at the same time its speed may be varied from 4 to 40 strokes per minute. The shaft is considered to be a remarkably clean piece of workmanship.

It is said that the Italian Government have contracted with the Millwall Ironworks for a war steamer of 2.030 tons, fitted with cupolas on the principle of Captain Coles. The engines of 700-horse power are to be by Messrs. Maudslay and Company.

It is proposed to extend the Helmsley and Ryedale Railway.

The Bristol Docks committee have brought up a report, in which they recommend the adoption of Mr. Howard's plans for the deepening and straightening of the river, so that two large paddle steamers could pass each other at any part on a neap tide, cutting through the "Horshoe point," and making a new steam basin near Cumberland Basin large enough for ocean steam traffic. The estimated expence is £557,495, the interest on which it is intended to provide for by the surplus revenue of the Dock and Wharfage estates, by small dues on corn and provisions, and tonnage dues on ships in harbour over two months. An alternative plan by Mr. Howard was estimated at £409,275. Both of the plans will be discussed at the next meeting of the Town Council.

Messrs. Glass and Elliot in a communication to us, say: We are perfectly confidant that a good and durable submarine cable can be laid direct from Ireland to Newfoundland, and are willing to undertake the contract upon the following conditions: 1. That we shall be paid each week our actual disbursements for labour and material. 2. That when the cable is laid, and in working order, we shall receive for our time, services, and profit, 20 per cent. on the actual cost of the line, in shares of the company, deliverable to us in twelve equal monthly instalments, at the end of each successive month whereat the cable shall be found in working order. We are so confident that this enterprize can be successfully carried out, that we will make a cash subscription for a sum of £25,000 sterling, in the ordinary capital of the company, and pay the calls on the same when made by the company. Annexed we beg to hand you, for your guidance, a list (which appeared in the MECHANICS' MAGAZINE, March 7, 1862, p. 159), of all the Submarine Telegraph Cables manufactured and laid by our firm since we commenced this branch of our business, the whole mileage of which, with the exception of the short one between Liverpool and Holyhead, which has been taken up, is at this time in perfect and successful working order. The cable that we had the honour to contract for, and lay down for the French government, connecting France with Algeria, is submerged in water of nearly equal depths to any we should have to encounter between Ireland and Newfoundland. You will permit us to suggest that the shore ends of the Atlantic should be composed of very heavy wires, as from our experience, the only accidents that have arisen to any of the cables that we have laid have been caused by ships' anchors, and none of those laid out of anchorage ground have ever cost one shilling for repairs. The cable that we should suggest for the Atlantic will be an improvement on all those yet manufactured, and we firmly believe will be imperishable when once laid.

Mr. Murray, of 7, Gloucester Cottages, Park-road, Peckham, in a letter says:—"In your impression of the 17th instant, in the description you give of Murray's Chain Pump, you say they have plates of wood. I beg to state they are plates of iron, with steel edges called lifts."

Mr. William Austen, of Milford, says: Your correspondent "Civillian's" letters in the two last numbers are much to the purpose, and show he has taken a great interest in the subjects he handles so well. I have lately proved the theory and practice of round and flat end projectiles by relative stages with punches and sledge hammer blows on iron plates placed on the anvil over *orifice,* and also on the *solid anvil face.* The last proves necessity of backing far superior to that which wood side grain would afford. I have suggested wood end grain as a backing, and also sand rammed hard, which is the nearest rigid backing to iron itself that I can think of. It is a well known fact that iron would be (in pig ballast or blocks) the best backing to armour plates, but it would conduct vibration on shocks, and the weight would never do for ships' armour, for they would turn upside down in a rough sea. The superiority of flat end plugs or sections of steel bolts or columns for destruction of enemy, beyond that effected by round canon balls of lead or iron, is proved by practical trials I have made, and which shows we have been firing the pills instead of the boxes, if I may use such a simile; but such is the fact, and a few experiments with steel plugs and 68-pounder guns would soon prove the *best* and *worst* armour plates and backings.

Mr. A. Rosse, of Walden House, writes:—Perhaps some of your readers can tell me where velocipedes are to be purchased? I mean good ones, upon three or four wheels. In some localities, I have been told, they abound, but I have never been fortunate enough as yet to meet with a really strong, well-made machine. I live in hope of such things becoming more common.

Captain Porter writes: I always read the letters of "Civilian," so ably written, in your Magazine. From what he states in his letter of Friday last, I suspect he is not aware that I proved in the barrack square of the 1st Horse Guards, then commanded by Colonel Hall, now General, and in presence of his whole regiment, that I pierced a steel cuirass with a flat-fronted steel elongated shell, discharged from the rifle barrel of Staudenmeyer's air gun. Lord Orkney turned in his lathe at Taplow this steel shell at my request, and was present and delighted at its execution.

On Monday last an important addition to the fire extinguishing apparatus, at the disposal of the fireman in the International Exhibition, was made in the form of a new patent steam fire-engine, placed near the Cromwell-road entrance. This engine, which is by Shand and Mason, of Upper Ground-street, Blackfriar's-road, is similar to one belonging to the London Fire Brigade, which was worked before the Jury, Class 8, on the first of July last. The report of the lately published summing up is as follows.—"The steam pressure was well-sustained, and continued working the entire day, without accident, concluding in the evening by throwing a good vertical jet." The engine has since the above trial worked most successfully at fifteen fires. Messrs. Shand and Mason have, we understand, made great improvements in the boiler of this machine, so that in the engine now in the Exhibition, steam of 50 lbs. pressure can be readily obtained in twelve minutes from lighting the fire, cold water being used, and at this pressure effective work can be done, the full working pressure being from 80 lbs. to 100 lbs. on the square inch, when 200 gallons per minute is pumped through an inch jet pipe to the height of one hundred and fifty feet; the weight of the engine does not, we believe, exceed 33 cwt., and this with the hose and firemen is conveyed rapidly to a fire by two horses. We trust that this engine will not be called into requisition during its short stay in the Exhibition, but as the most da gerous period with regard to fire will be when the packing and removing goods is going on, we congratulate Captain Bent and the fireman upon having such a powerful agent at their disposal.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

THE Abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following Table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved, and combined with all the advantages of a division into classes. It should be understood that these abridgements are prepared exclusively for this Magazine from official copies supplied by the Government, and are therefore the property of the Proprietors of this Magazine. Other Papers are hereby warned not to produce them without an acknowledgement:—

STEAM ENGINES, &c., 952, 956, 963, 979.
BOILERS AND FURNACES, 940, 988.
ROADS AND VEHICLES, including railway plant and car-

929. G. COLLIER and J. COLLIER. *Improvements in looms for weaving carpets and other pile fabrics.* Dated April 2, 1862.

This invention consists in a new arrangement and combination of mechanism for inserting and withdrawing the pile wires in weaving carpets and other pile fabrics, whereby greater simplicity and accuracy of the working parts are obtained, so that the loom is enabled to run at a quicker speed. The wires are withdrawn from the fabric by means of a hook mounted on or fixed to a carriage capable of sliding to and fro on a guide rail, and they are inserted into the shed by an instrument which may be called a spring clip, and which is also guided in its to-and-fro movement by an inclined rail or slot, which the patentees prefer to be fixed at one end, and capable of slight movement at that end nearest the fabric. The withdrawing and inserting instruments are connected together in such manner that they move simultaneously to and from the fabric, and the wires are transferred from the hook to the spring clip by means of the inclined guide rail or slot before named, which forces the spring clip on to the wire head, whilst the latter is still held by the hook, and just before the wire has been completely withdrawn, the hook being freed from the wire head immediately the return motion is given for inserting the wire. When the wire is inserted into the shed, the lay beats it up to the fell of the cloth, where a catch holds it in position to be woven in. The point end of the wire, when withdrawn from the fabric, is carried opposite the open shed by a lever having a recess in its upper end, capable of receiving and sustaining the wire, the lever being operated by a suitably-shaped cam, so as also to support and guide the wire during insertion. *Patent completed.*

930. B. BLACKBURN. *Improvements in apparatus for lubricating locomotive and other axles.* Dated April 2, 1862.

These improvements have reference to a previous patent granted to the present patentee, and dated 13th June, 1861, No. 1,524, and are as follows:—Instead of placing the packing or stuffing used for spreading the oil on the journal below the journal, it is fixed above the centre of the journal, and in contact with it, and in such a position that the packing and the brass bearing shall wear away simultaneously together, and thus the packing remain always in contact with the upper part of the journal as long as the bearing lasts. *Patent completed.*

931. S. HUNTER. *Improvements in anchors.* Dated April 2, 1862.

This invention is not described apart from the drawings. *Patent completed.*

932. T. MOORE. *Improvements in winding apparatus, especially applicable to fishing lines and log lines, and in leaders or travellers to be used therewith, which leaders or travellers are also applicable to working ships' sails and other purposes.* Dated April 2, 1862.

This invention is not described apart from the drawings. *Patent completed.*

933. J. T. LOFT. *Improved machinery for printing in colours.* Dated April 2, 1862.

This consists chiefly in a novel mode of applying the colours to the set or series of printing surfaces which together constitute the design to be printed. The patentee proposes to employ both raised and sunk printing surfaces, but in general he prefers to operate with raised surfaces, the invention being most applicable to block or type printing. The paper to be printed he provides by preference, in the form of a roll, which he mounts on the tympan of the press. For printing in three, four, or more colours, he provides, say three plates or forms, which together constitute the compliment of the design to be printed. These he arranges side by side on the sliding bed of the press, and at such distances apart as will ensure their giving a proper register. On a level with this bed, and close beside it when the bed is at its backward reach, he places an inking or colour table, the surface of which is composed of detached parallel slabs. A traversing inking roller receives the colours delivered simultaneously from a series of fountains set at the end of the table, and thus charged, it is passed over the table, receiving in its passage a slight endway motion for the purpose of spreading the colour the more evenly. From the inking table the inking roller passes to the printing surfaces, and imparts to them at one operation broad or narrow lines, as the case may be, of the various colours with which it is charged. *Patent completed.*

934. W. CLARK. *An improved apparatus for manifold writing.* (A communication.) Dated April 2, 1862.

This relates to an improved manifold writer for obtaining copies of deeds, documents, or papers, letters, music, &c., by a single penholder, bearing at one time on several sheets of paper. The copies may also be obtained in triplicate. The apparatus and its accessories consists, first, of a desk or table of desired form, forming a support for the hand. Second, of an improved holder for steel or other pens. Third, of an improved inkstand, forming an indispensable adjunct to the penholder, as does the letter to the desk or table. *Patent completed.*

935. W. LEOPARD. *Improvements in railway-brake apparatus.* Dated April 2, 1862.

This relates to the application of self-acting brakes; that is, brakes in which the momentum of the carriage is utilized to produce the power applied, and consists in an arrangement of parts whereby the power is transmitted from the shaft receiving the impulse from the running wheel axle of the carriage to the brakes. We cannot give space to the details of the invention. *Patent completed.*

936. W. CLARK. *Improvements in the manufacture of carbonic acid.* (A communication.) Dated April 2, 1862.

This improved process for the manufacture of carbonic acid is as follows:—The inventor takes two parts of filings and one of copper turnings, and roasts them to a deep red heat on the sole of a cast iron retort (open at the two extremities) under the action of the current of air which is established; the copper rapidly absorbs the oxygen, and is transformed into oxide of copper. When the whole of the copper is converted into a black powder it is taken out of the retort and allowed to cool, and about 6 per cent. in weight of finely pulverized charcoal added to it. The mixing may be effected either with a shovel or by slight trituration; or, lastly, by adding the charcoal diluted in water in the form of a clear solution, and then allowing the whole to dry in a furnace. The mixture of charcoal and oxide of copper is then placed in the retort, and the carbonic acid begins to disengage at a slightly raised temperature, which continues until the whole of the charcoal of the mixture has been consumed by the oxide of copper, and the gas is then collected in a gasometer. About 250 lbs. of the mixture will furnish 50 lbs. of carbonic acid, equal to 10 cubic yards. When the operation is over the retort is opened at both ends, and the copper which has furnished the oxygen to the charcoal receives a fresh supply from the atmospheric air, and thus becomes revivified with the greatest facility. It may then be removed from the retort, cooled, and mixed with charcoal, and then made to undergo a similar treatment to the foregoing for producing the same result. The copper should be washed from time to time in plenty of water, in order to remove the carbonates of salts resulting from the combustion of the charcoal. *Patent abandoned.*

937. G. REBOUR. *A permanent autographic log serving to measure, and if needed to retrace graphically the swiftness and sailing of a ship, the rapidity of streams, and the propelling of rising and ebbing tides.* Dated April 3, 1862.

This permanent autographic log is essentially composed of an archimedian screw, fixed on the quarter near the stern of the ship, and sufficiently below the water line to secure constant immersion. The furrow or thread and the size of this screw are so calculated that it may make one complete revolution for each unit of measurement run by the vessel. The axle of this screw, which is only to turn in one direction, is furnished with toothed gearing at an angle of 45 deg., which communicates the rotary motion of the screw to a horizontal shaft passing within the ship, the other end of which transmits it to a vertical shaft pivotting in sockets. At the point where the observation is to be taken is placed, tangentially to the vertical shaft, the handle of a striking index, balancing easily on its fulcrum, and running on the ridge of a prismatic circle perpendicularly to the vertical shaft. At some point of its circumference, this circle presents a section cut perpendicularly on one side, and following an inclined plane on the other; opposite this section is placed a gong or sounding plate, on which the hammer or index strikes when falling into the solution of continuty of the circle. With this instrument the officer of the watch has but to listen for a minute how many times the gong has been struck, to know that the ship has run a certain distance, and that without possibility of error. *Patent completed.*

938. W. HELME. *Improvements in firelighters.* Dated April 3, 1862.

The patentee claims, 1, constructing fire-lighters out of the waste blocks of wood, either singly or combined, from which cylindrical pieces for forming bobbins, reels, &c. have been extracted, so that the whole of the remaining portion remains connected together. 2, The construction of fire-lighters, wherein a number of incisions are made in a solid block or wood, so that a number of projecting pieces are formed which remain connected together, by reason of the incisions not having been cut right through the block, as described. *Patent completed.*

939. R. MORTON. *Improvements in refrigerators or apparatus for cooling liquids, parts of which improvements are also applicable to distillation, surface condensation, heating air for blast furnaces, and other similar purposes.* Dated April 3, 1862.

This relates to refrigerators in which flattened or other shaped tubes are used for cooling liquids, worts, or other fluids. In these refrigerators the hot water or other liquid enters the box or case at the opposite end to that at which the cold water enters, passes underneath one pipe, rises to its level, and then falls over the next pipe, and so on alternately over one and under the next to the end of the apparatus, where it flows into a reservoir at the end, and from thence into the tun, the cold water passing away at the opposite end. The patentee by preference uses flattened tubes made of copper thoroughly tinned, or other suitable metal or otherwise; these tubes are strengthened internally with a sufficient number of stays properly fixed the full length of the tubes. These tubes are inserted at each end into strong plates of copper or other metal, perforated at proper distances to receive the tubes, which are then connected alternately with hollow caps, or discs of copper or other metal secured to the plates, and over the ends of two or more tubes, so as to admit of a continuous flow of cold water or other liquids through the tubes. A longitudinal rib is fixed on the top of each alternate tube of sufficient depth, and the bottoms of the alternate tubes are also connected by a corrugated strip of copper or other metal, thereby forming a series of compartments between the tubes, causing a continuous flow of hot worts or other liquids alternately under and over the external surfaces of the tubes, the hot liquid and cold water thus flowing in opposite directions, and being discharged at opposite ends. The apparatus is fixed to a case of copper or other metal, and screwed in a strong wooden or metallic frame, and can be used with open or closed top to prevent any atmospheric action on the worts. Their action can be reversed if preferred, the worts flowing inside the tube, and the water outside the tubes. *Patent completed.*

940. G. BOWER and J. QUALTER. *Certain improvements in metallic pistons.* Dated April 3, 1862.

This consists, 1, in the novel application and use of a spring constructed similarly to a coach spring, and interposed between the interior surface of the V packing ring, and the wedges, screws, or other medium employed to expand the packing rings. This spring, composed of a series of plates, as a "coach spring," is the peculiar feature of the invention. 2. The invention consists in the novel use of a cam or cams, or eccentricities within the piston to act upon and expand the packing; their action being governable from the exterior or interior of the piston. *Patent completed.*

941. J. NEWTON. *Improvements in the construction of breakwaters, piers, and sea walls.* Dated April 3, 1862.

This consists in forming suitable hollow iron or timber casings, braced or stiffened, as may be required, which are lowered or placed on the bottom of the sea, or beds of rivers, &c. The casings are then bolted, rivetted, or otherwise fixed and secured together. The further ingress of water is then prevented by clay and sheet lead, or other substances, placed round the base of the casings when sunk. The water in the casings is then pumped or taken out to enable workmen to perform any operations. *Patent completed.*

942. G. HUNTER. *Improvements in machinery and tools for cutting, sawing, and planing stone, marble, and slate.* Dated April 3, 1862.

This invention consists in certain arrangements of machinery for mounting saws, surfacing plates, or other cutting tools, whereby they may be worked either vertically, horizontally, or at an angle; also in the constrnction of improved tools to be used therewith, or with any other stone-cutting machinery. The spindles of the surfacing plates or saws are mounted in brackets capable of being turned to any angle with the length or the breadth of the stone to be operated upon. The stone rests upon a turn-table, which lies upon a table having a traversing motion imparted to it, so as to feed the stone forward when sawing or surfacing, and arranged in such manner as to be readily put in gear with a quick reversing motion, so as to travel like an iron planing machine when necessary. The turn-table has slots formed in it, and upon the under table are long slides, acted on by screws, having a number of holes in them, wherein to insert grippers through the slots in the turn-table for the purpose of securing the stone and the turn-table. The turn-table is worked by worm-wheel and worm, or by wheel-rack and screw, or any other convenient method. The machine is also provided with planing tools for the purpose of planing off the circular marks left by the disc, or, if for slate slabs, for planing them in the usual way, before or after sawing them. The patentee makes the tools of bent steel, the size of which is regulated according to whether the stone is to be cut through or only surfaced; one end of the bent steel is worked bell-shaped, whereby the necessary angle is obtained as well as space for the tool holder. The tools may be semi-circular or flat, or pointed on the top side, according to the work required to be done. *Patent completed.*

943. R. M. TOOGOOD and J. LAYBOURNE. *An improvement in railway crossings.* Dated April 3, 1862.

This invention consists in forming welded cast-steel crossings by welding Bessemer or ordinary cast-steel rails from the point of the V or heart piece to the intersection of the two rails. *Patent completed.*

944. W. KEMP. *Improvements in the manufacture of silk pile velvet.* Dated April 3, 1862.

Here the patentee uses two pile warps, each having a complete number of threads. The warps are carried on two separate beams, and two pile warp threads (namely, one from each beam) are passed through each dent of the reed, and they make these two threads loop or pass over the wires alternately, that is to say, if one of these two threads loops or passes over the wire, the other is made to loop over the next. They also cause that portion of the pile warp, which at any moment is not engaged in making the pile loop, to pass on the surface of the fabric immediately under the pile loops formed by the other portion of the pile warps, so that the surface of the body fabric, the shoot of which may be of cotton, becomes coated with silk. In weaving velvet the patentees use only two shoots between the pile wires, and they still get a safe tie, as there are in fact four shoots between one loop and the next of the same pile thread. *Patent completed.*

945. M. AMOS. *Improvements in harrows.* Dated April 3, 1862.

Here the inventor forms numerous short bosses, each having a square hole horizontally through it, and in one surface of each boss a tooth is formed, and a tooth is also formed on the opposite side of the boss. These teeth he makes of different dimensions, in order that a harrow composed of these bosses may on one side have one class of teeth, and on the other side another class of teeth, and thus be suitable at different times to perform different classes of work. On to a square bar he places four or any other number of these bosses; and on the two ends of the bar he forms suitable hooks, eyes, or instruments for connecting the bars together end to end. He connects any desired number of these bars together end to end, according to width of harrow to be constructed. To connect together several of the rows of teeth thus produced, he uses chains which have square links at intervals in their length, according to the distance apart he wishes to have the severa

parallel rows of teeth; and before coupling the square bars end to end he presses such of the ends of these bars as may be required through square links of the connecting chains. By these means rows of teeth will be produced running in a direction from side to side of the harrow, and they will be connected by parallel chains running in a direction front to back of the harrow. *Patent abandoned.*

946. D. WILSON and E. A. COWPER. *Improvements in presses for pressing cotton, fibrous materials, and hay.* Dated April 3, 1862.

Here the patentees are able greatly to reduce the length of the trunk or box by making it with two of its sides (opposite the one to the other), capable of movement; these sides they combine with pressing apparatus, so that they become, in fact, the plungers of secondary presses. The box or trunk is filled with cotton or other fibrous materials, when its movable sides are most distant the one from the other, and when, consequently, the area of the trunk is considerably greater than that of the bale to be made; the first pressure is obtained by the inward movement of the sides, so as to contract the interior section of the trunk or box; the sides are then locked by suitable bolts or catches, and then the remaining pressure is effected by the piston or plunger of the principal press being, as heretofore, moved further and further into the trunk or box. *Patent completed.*

947. J. LEE. *Improvements in traction engines and boilers for traction, locomotive, and other purposes.* Dated April 3, 1862.

This consists in giving motion to the main or driving pair of wheels by a pinion on the crank shaft of the engine gearing into an intermediate wheel, on the axis of which is another smaller wheel, which gears into a toothed wheel on the axis of the main or driving wheels. The intermediate wheels turn on a stud which projects from the bracket, which carries the crank shaft; this stud, the crank shaft, and the axis of the main wheels are so placed that their centres are all in one vertical line. The improvements in boilers for traction, locomotive, and other purposes, consist in constructing them so that the horizontal tubes which pass from the fire-box conduct the products of combustion into a smoke box or chamber, from the top of which they pass away through vertical tubes, which rise up through the dome or steam chamber of the boiler, and on the exterior of the dome the tubes open into a chimney which can be turned down when the tubes require chimney. The smoke box or chamber above-named is formed by the plate, which receives the ends of the horizontal tubes from the fire-box, being bent at right angles, the portion bent down at right angles receiving the vertical tubes which rise up through the dome. *Patent abandoned.*

948. A. MANN. *Improvements in photographic apparatus.* Dated April 3, 1862.

This consists in certain improvements in photographic apparatus, being contrivances for obtaining an instantaneous exposure and closing of the lens, and for enabling the landscape photographer to secure impressions of clouds, or any desired atmospheric effect, along with the darkest foreground on the same plate. The invention, among other features, comprises an improved apparatus forming a new photographic camera shutter for uncovering and covering the lenses more conveniently, and admitting the requisite amount of light in a much shorter time than by any existing arrangement. The invention is not fully described apart from the drawings. *Patent completed.*

949. W. A. RICHARDS. *Improvements in the manufacture of bags, and in fastenings and locks for bags, part of the invention being also applicable to purses, cigar cases, reticules, and other similar articles.* Dated April 3, 1862.

In manufacturing bags in which frames are used, the patentee first cements to the metal intended to form the frame, a tube of leather of larger diameter than is required to cover the metal, and he forces the excess of leather into the recess, hollow, or opening formed by or left in the metal for the reception of the bag body, so that the leather forms a lining to the recess. He provides or forms the edge of the bag-body with a cord or other material, or portion thicker than the substance or rest of the said body, and he introduces the corded or equivalently prepared margin into the recess or opening in the clothed metal, the edges or sides of which he next forces against or towards the surfaces of the margin. Instead of metal and leather other materials are employed in the manufacture of bags may be treated in like manner for the same purpose. We cannot give space to the details of the fastening. *Patent completed.*

950. H. T. HASSALL and M. BURKE. *Improvements in reclining or invalids' chairs, and in swinging or ships' chairs.* Dated April 3, 1862.

This invention is not described apart from the drawings. *Patent completed.*

951. J. F. WOODALL. *Improvements in ventilating carriages for common roads.* Dated April 4, 1862.

The patentee claims the application to carriages or vehicles for common roads wherein fresh air is admitted through openings formed in the front or sidet, or both, of the carriage, whilst the internal air is roused to escape either directly through an opening formed in the roof, or through an opening into a conducting tube, whence it passes out through an opening at the back of the carriage, the said openings for the ingress and egress of the air being either uncovered or more or less hidden by suitable gratings or ornaments, and either provided or not with suitable valves for regulating at pleasure the extent of ventilation as described. *Patent completed.*

952. J. C. KAY and W. HARTLEY. *Certain improvements in steam engines.* Dated April 4, 1862.

This consists in certain arrangements of the air pump, condenser, and hot well of horizontal and other condensing steam engines, and of the suction and delivery vales in connection therewith. The objects of the improvements are, by increasing the effective condensing surface, and providing for the free discharge of air and water, to secure a good vacuum, to simplify the mechanical arrangements for working the air pump, to economize space, to obtain greater stability, and to afford facility in obtaining access to the valves and various parts. The invention is not described apart from the drawings. *Patent completed.*

953. F. SPENCER. *Certain improvements in looms for weaving.* Dated April 4, 1862.

This has reference to that part of the loom known as the "letting off" motion, and consists in supplying the warp beam upon rollers, to which a positive uniform motion is given at every pick, or after every two or more picks. The motion for the rollers may be derived from the tappet shaft, or other convenient part of the lever, and as the surface of the warp bears on the rollers, it is evident that the motion given to the rollers will unwind a uniform quantity of the warp threads. In order to prevent the slipping of the warp beam, a weight may be suspended to a band passing over the ends of the beam. *Patent abandoned.*

954. W. RYDER. *Improvements in the construction of machines for forging metals.* Dated April 4, 1862.

This has reference to a previous patent dated 8th Feb., 1841. (No. 8,835.) In performing the present invention, the inventor makes the sockets in which the blocks work round. He also makes the bushes or bearings in which the eccentric shaft revolves of a comical form, and applies a screw net to each end of these bushes, by slackening one of these nets and tightening the other; each brush can be adjusted independently of the others, thus dispensing with the usual caps and bolts. The last part consists in making the lower part of the piece which communicates the motion from the eccentric to the block of a partially spherical form, instead of partly cylindrical. *Patent abandoned.*

955. F. C. BAKEWELL. *Improvemnnts in letter-printing machines.* (A communication.) Dated April 4, 1862.

This invention is not described apart from the drawings. *Patent completed.*

956. T. SILVER. *Improvements in governors for regulating the speed of steam and other engines.* Dated April 4, 1862.

These governors are composed of two parts, one part being rotated by the engine or machine to be regulated, and the other part by an independent engine, or any other convenient means of obtaining uniform motion; or, when not rotated, it may be connected to any convenient arrangement for obtaining uniform power of resistance. Wheel gearing is employed intermediately for converting the difference between the motions of the two parts composing the apparatus into a movement, by which the throttle-valve or other means of regulating the admission of power to the engine is effected. A fly-wheel is employed, and it may either be keyed fast upon the shaft when the shaft is free to revolve in the driving pulley and other portion of the apparatus; or, when the driving pulley is keyed fast to the shaft, the fly-wheel mounted thereon is, together with its portion of the apperatus, free to revolve and may revolve in one direction or the other within the limit assigned to it. *Patent completed.*

957. L. LINDLEY and F. TAYLOR. *Improvements in sewing and embroidering machines.* Dated April 4, 1862.

This invention is not described apart from the drawings. *Patent completed.*

958. H. FLETCHER. *Improvements in valves for hydraulic presses and in apparatus connected therewith, for making or pressing blocks or bricks of coal or other material.* Dated April 4, 1862.

Here the inventor employs a self-acting valve, such as a double or compensating valve, constructed of valves of unequal size, and he so arranges them that, when the pressure of water is exerted it tends to open them, and they compensate each other, except by the difference of their sizes. This difference or inequality is compensated by means of a lever and weight or spring, or by other suitable means, so that the valves may be kept to their seats or bearings, by a force which may be adjusted or varied as desired. *Patent abandoned.*

959. G. MOULTON. *Improvements in pentagraph machines, used for tracing or engraving rollers or cylinders employed in printing calicoes and other surfaces.* Dated April 4, 1862.

This consists, 1, in the use of a circular tool-holder, having a mortice for placing a number of points around the cylinder to be traced or engraved. The said circular tool-holder is formed either in an entire circle or a segment of a circle, and in both cases the tool-holder is supported at two parts, placed in suitable positions. 2, In constructing the supports or bars for carrying the said circular or segmental tool-holder; so that they may be parted asunder and made to travel in opposite directions for the purpose of reversing the patterns. 3, In raising and lowering the table which carries the pattern plate, instead of having it stationary as at present, for the purpose of regulating or adjusting the length of the levers from the cylinder to the pattern plate, and thereby enabling the sketch to be adopted to any slight differences required on the cylinders. 4, In forming slots in the vertical arms or levers, so that the patentee may employ different lengths of the bracket that carries the tracer carriage and its bar, and also the shaft that carries the ratio pulley, for the purpose of altering the dimensions. *Patent completed.*

960. A. WOODHOUSE and T. HUNTER, JUN. *Improvements in the arrangement of kilns and flues for burning bricks, tiles, quarries, and other like articles, and in utilising the waste heat of the said kilns, and in stoves for drying bricks, tiles, quarries, and other like articles.* Dated April 4, 1862.

This consists in the construction or arrangement of kilns for burning bricks, tiles, and other articles, and in stoves for drying bricks, tiles, &c., the object of the invention being to use the waste heat obtained from one or more kilns to heat the bricks, &c. in an adjoining kiln or kilns, and afterwards to conduct the said waste heat to stoves for drying bricks, tiles, &c. *Patent abandoned.*

961. A. J. HALL. *Improvements in instruments for drawing ovals.* Dated April 4, 1862.

This invention is not described apart from the drawings. *Patent abandoned.*

962. M. BUTCHER. *Improvements in apparatus for reefing and furling sails from the deck.* Dated April 4, 1862.

Provisional protection has not been allowed for this invention.

963. S. FIELDING, S. FIELDING, JUN., R. FIELDING, and T. FIELDING. *Improvements in valves and in apparatus for lubricating the same and other parts of steam engines.* Dated April 4, 1862.

This consists in a new arrangement of valve which is actuated by a rotary movement derived from the main shaft by toothed glaring, or by any other mechanical contrivance. *Patent completed.*

964. R. A. BROOMAN. *An improved case for holding balls and reels of cotton, silk, and other threads.* (A communication.) Dated April 4, 1862.

This case is formed of metal, ebonite, gutta-percha, or other suitable material, and with two compartments, each of which is provided with a cover, and kept separate by one division plate or bottom common to both compartments. Each cover has a hole formed in it for the passage of the thread from the ball or reel, and there is also a notch in which the thread is engaged to prevent it running back inside the case. Each compartment is made sufficiently large to contain one ball or reel of thread. The thread is kept clean, and is not liable to become entangled when these cases are used. *Patent completed.*

965. J. SCEALES. *Improvements in steering ships.* Dated April 4, 1862.

This invention is intended chiefly to apply to the steering of ships of great length, and consists in fitting one or more rudders on the sides of the vessel in addition to the ordinary rudder. The additional rudder or rudders when not at work enter a recess or recesses formed in the ship's side to receive them, in order that there shall be no projecting surface to interfere with the ship's way when the additional rudder or rudders is or are not in action. *Patent abandoned.*

966. W. E. NEWTON. *Improvements in the manufacture of iron and steel.* (A communication). Dated April 4, 1862.

The patentee claims, 1, The purification of crude pig or cast iron, and its direct conversion into cast steel or refined iron, by successive and alternate oxidations and reductions. 2, The use of steam as a chemical agent in the operation of the direct conversion of the metal into iron or steel, by injecting or passing the steam through the metallic bath, under pressure, in a reverberatory furnace, as set forth. 3, The simultaneous use of air and steam passed or forced through the fluid metal for producing oxidation in a reverberatory furnace, as set forth. 4, The simultaneous use in the same both of molten metal of a combination of air, steam, and gas, as described. 5, The use of reducing gases, acting in the interior of the fluid metallic bath, and alternately with the oxidizing agents or gases. 6, The employment of steam acting mechanically as a means of conducting air or gases as applied to the above operation of converting molten pig or cast iron into steel or iron. 7, The injection of coal dust, or pulverized charcoal, or carbonaceous matter, into the metal bath, for recarbonizing the oxidized iron, as set forth. 8, The arrangements of the reverberatory furnace with beds or vessels for containing the molten iron in duplicate, and mounting these beds or vessels on wheels or moveable frames, so that they may be moved in and out of the furnace, as described. 9, The use of a raised bridge for separating the moveable beds or vessels, and providing the said raised bridge with a layer of fuel for assisting the reducing operation. 10, The application of the charcoal cement for the formation of the beds of the moveable vessels. *Patent completed.*

967. W. E. NEWTON. *Improvements in pumps for ships' use and other purposes.* (A communication.) Dated April 4, 1862.

This consists in the arrangement of inclined valves or inclined seats, in combination with a horizontal or other suitable pump cyclinder, and with a piston to which a reciprocating motion is imparted by a sliding plate operated upon by a three-armed oscillating lever, whereby a pump is obtained which can be easily operated, and will throw a large stream of water, and in which sand or other solid matters that may be drawn in by the pump will be prevented from lodging on the inclined valves or seats, and obstructing the operation of the pump. Also in the use of hinged swinging bolts which are made to catch into slotted ears made on flanges that project from the bottom of the air vessel over the ends of the valve chest, which is placed on the upper side of the pump cylinder. By the above improvements the air vessel can be readily fastened and unfastened from the pump. A packing is provided for making an air-tight joint between the lower flange of the air vessel and the upper edge of the valve chest. *Patent completed.*

968. W. E. NEWTON. *An improvement in projectiles for ordnance.* (A communication.) Dated April 4, 1862.

This projectile is constructed externally of cylindrical or other form to fit the bore of the gun, and is hollowed out internally in taper form. By this means a sharp front edge of circular or annular form, corresponding with the bore of the gun, is made at the front end of the projectile, and a hollow passage is made clear through the projectile, which is provided at its rear end with a sabot or plug, which closes the aperture, and also assists in expanding the rear end of the projectile, so as to make it fit the bore of the gun. *Patent abandoned.*

969. J. NOCK and W. K. PRICE. *An improvement or improvements in gas cooking ranges.* Dated April 4, 1862.

This consists in lining the inside of such ranges with glazed tiles or slabs placed a slight distance within the outside casing, the effect of which is, that a much higher temperature can be obtained with a smaller consumption of gas. *Patent abandoned.*

970. J. D. HUMPHREYS. *Improvements in furnaces and machinery employed in the manufacture of compound fuel and other matters.* Dated April 4, 1862.

In carrying out one portion of this invention the furnace employed is constructed on the reverberatory principle, so that the heat beats down into the chamber (containing the substance to be heated), in its passage from the fire to the chimney. The substance to be heated is supplied into this chamber by a feed-wheel working air-tight in the crown of the furnace. In the chamber of the furnace is fitted a

agitator to keep the fuel constantly stirred while subjected to heat. At the bottom of the chamber is a worm which moves the heated fuel out as required by the moulding machine. Inside the crown of the furnace is fitted a light metal box, containing lead or other substance that melts at about the degree of heat that it is required to raise the furnace to; an ordinary governor is fixed above the furnace, the spindle of which is connected with a disc or plate that revolves in this melted substance. The rise and fall lever of the governor is connected to a large throttle-valve damper placed under the fire-door. The governor is driven by a friction-coupling, so as to allow it to stand still with the damper open when the substance in the box is hard, and to cause them to revolve and close the damper as soon as the substance melts. Or a blowing fan may be regulated by a governor on the same principle, and thus may the heat of the furnace be regulated. *Patent abandoned.*

971. M. Walker. *Improvements in breech-loading rifles and other fire-arms, and in ordnance.* Dated April 4, 1862.

Here the inventor constructs breech pieces for breech-loading riles without requiring screw actions or complications of levers, by cutting away or grooving out the stock at or near the end of the barrel, and fitting the same with a breech plug or piece for stopping the breech end of the barrel, capable of being turned on a centre to out of the same line with the breech end of the barrel to load the rifle, Thus the inventor has a breech plug made to enter the end of the barrel and close the same, which plug should be made in two parts, united by a joint, the pivot of which joint should protrude at each side of the plug and slide in slots at each side of the breech piece, and one part, that furthest from the end of the barrel when in a line with it, being capable of being turned on the said joint, and allow the whole plug to be moved so as to admit the charge, after which the plug is to be placed in its former position, closing the breech end of the barrel, ready for firing. He affixes the nipple in the barrel, and connects the barrel to the stock in the ordinary way. *Patent abandoned.*

972. W. Begg. *Improvements in consuming smoke, and in furnace bars and bridges for effecting the same.* Dated April 5, 1862.

This relates to the admission of air heated to a high heat at the bridge of the furnace, in order to produce the combustion of the smoke, and consists in making all the furnace hollow from end to end, or nearly so, and all in one length, whereby a great amount of heating surface is obtained to heat the air, and which becomes highly heated therein. The back ends of the bars open into the fire bridge, which the patentee makes altogether hollow, and forms numerous perforations therein over the crown, and in front (towards the furnace) near the top of the bridge. *Patent completed.*

973. H. J. Simlick. *Improvements in the manufacture of vesuvians or cigar lights.* Dated April 5, 1862.

This consists in the application of a piece of tube on the splint or piece of wood of which the stem of the vesuvian is made, and in applying the combustible material on the end thereof, instead of on the splint itself, by which the combustible material is prevented dropping off when ignited. *Patent abandoned.*

974. J. Colling. *Improvements in apparatus for reefing ships' sails.* Dated April 5, 1862.

In reefing sails, the patentee uses a roller on which he winds the sail as hitherto, which roller he disposes in front of the yard, so that the full effect of the area between the yards may be rendered available. He mounts and supports the roller by bearings from the yard; two of such bearings carry the pivots on which the roller revolves, while others carry blocks or sheaves, through which the reefing chains or ropes are led on to the rollers. These reefing ropes or chains have the effect of rotating the rollers, and also in assisting to hold the roller and yard in position to slide freely up and down the mast while reefing or unreefing the sail, by reason of the conduct by and effect of their leading blocks and bearing standards before-named. *Patent abandoned.*

975. A. Clark. *Improvements in the manufacture of revolving window-shutters and blinds in window sash bars and plates, also in apparatus used in such manufactures.* Dated April 5, 1862.

This consists—1, in the application of flat, coiled, or volute steel-tempered springs, combined with a barrel or case revolving upon an axis for rolling up the shutters. 2. Part of the invention refers to mortising holes through the laths of revolving shutters, to receive tapes or steel strips for connecting them together. The third part relates to the manufacture of sash bars and mouldings and brass stall-board plates. *Patent completed.*

976. L. Faconnet. *A new kind of tiles.* Dated April 5, 1862.

This comprises various features of novelty in the form of tiles, one being that, on a roof covered with them, no overlapping will be apparent; thus, if the roof be covered with scale or shell-shaped tiles, it will form a perfectly plain surface, as if made of one single piece. This is effected by giving the tile several real or apparent thicknesses, making it, for example, thinner at top and bottom than in the intermediate part, that which is alone visible when the tile is placed. These tiles are provided with certain ribs, notches, and grooves for strengthening, fixing, and carrying off water. *Patent completed.*

977. R. A. Kobitzoch. *Improvements in diving apparatus and apparatus to be used for working in deep water.* Dated April 5, 1862.

This consists in a method of constructing and arranging apparatus whereby the diver is enabled to remain for many hours under water, shut out from all communication with the atmosphere, and protected from the pressure and coldness of the water, and allowed to move about freely in all directions. The details are voluminous. *Patent abandoned.*

978. T. Critchlow. *Improvements in planing machines.* Dated April 5, 1862.

This relates to certain improvements in planing machines for planing metal, and consists in adopting to such machines two separate and distinct cutters, fitted to one and the same cross slide, the cutting edges of the cutters being placed in opposite directions, so that a cut will be made at each forward and backward stroke of the table. Suitable provision is made for bringing the proper tool into action at the end of each cut. Or instead of using two separate cutters, a duplex cutter may be employed, having one stem or shank, and two cutting edges in opposite directions. *Patent abandoned.*

979. B. Thompson. *Improvements in steam engines.* Dated April 5, 1862.

This consists in a method of constructing steam engines for the combined use of high-pressure power and vacuum power, with slides or valves so arranged or disposed as to effect the division of the steam with which the engine is served into separate portions, after such steam shall have given out its pressure power, as distinguished from its vacuum power, and so that a portion shall be suffered to escape and a portion may become condensed. *Patent completed.*

980. C. S. Duncan. *An improved method of an apparatus for ventilating, cooling, or suppressing fire in public and private buildings or rooms.* Dated April 7, 1862.

This arrangement consists essentially in an arrangement of pipes for distributing water over the roofs of buildings or rooms for the purpose of cooling them, or for extinguishing fire, and in carrying such pipes into every room of a warehouse or other building. *Patent completed.*

981. T. Smith. *Improvements in machinery for cutting and shaping screw-bolts and other articles.* Dated April 7, 1862.

According to this invention, the cutting tool for shaping the body of the bolt and squaring the bolt-head consists of a steel die with a hole through it of the diameter of the screw-bolt, and one end is furnished with cutting edges. The head of the bolt to be operated upon is held in a chuck attached to a spindle, to which motion is given by steam or other power, and the cutting tool is pressed against the screw-bolt by a rod acted upon by levers and weights. When the cutting tool is being pressed against the screw-bolt, the inner cutting edges reduce the body of the bolt to its proper diameter; and when the cutting edges come against the bolt-head, they square it up. As soon as the operation is completed, the attendant, by acting on a lever, draws the cutting tool away from the screw-bolt, which is then taken out of the chuck, and another one put in its place to be operated upon in the same manner. The point of the screw-bolt is then operated upon by a countersunk cutter, somewhat like the tool known as a rose bit, and a similar instrument is employed for rounding up or polishing the heads of the bolts. These instruments are necessarily pressed against the point and head of the screw-bolt, which is held in a revolving chuck; or the cutting instrument may revolve, and the bolt or other article may be stationary. *Patent abandoned.*

982. W. Simons. *Improvements in constructing ships or vessels.* Dated April 7, 1862.

The patentee claims, 1, securing the wooden planking to the iron frames or beams of ships or vessels by means of screw-bolts, or other bolts of iron or steel, partially coated with copper, yellow metal, or a combination thereof, substantially, as described. 2, Introducing diagonal metal bars or plates between the wooden planking and iron frames of ships or vessels, alone or along with reverse diagonal bars or plates on the insides of the frames, substantially as described. 3, Fastening to each other the outside planks of iron-framed ships or vessels with oblique or diagonal seam bolts, substantially as described. *Patent completed.*

983. A. Harris. *An improvement or improvements in the manufacture of gun barrels.* Dated April 7, 1862.

This invention consists in making gun barrels by welding together, by means of rolling, drawing, or forging a series of bars, having, by preference, nearly a wedge shape, that is, such a shape that, when a series of the said bars are placed together side by side, they have nearly the figure of a hollow cylinder or tube. *Patent completed.*

984. E. Welch. *Improvements in register stoves and fire grates, and in ovens and kitchen ranges.* Dated April 7, 1862.

This invention is not described apart from the drawings. *Patent completed.*

985. G. Haseltyne. *Improvements in lamps especially designed for burning hydro-carbon oils.* (A communication.) Dated April 7, 1862.

The first part of this invention consists in an improvement on the "Argand burner," by which complete combustion is effected without a "button," and with a short chimney, not exceeding three inches in length. Instead of the cylindrical wick tube of the Argand burner, several tubes are employed, being arranged concentrically in the form of a truncated cone, the upper ends nearly touching one another, and the lower ends being considerably separated, so as to admit a free access of air inside. And instead of the common button an inverted conical deflector is used, placed centrally within the space formed by the wick tubes. This arrangement makes a practical portable coal oil lamp. The second part of the invention consists in the use of separate serrated wheels for raising and adjusting the wicks independently of each other. *Patent completed.*

986. W. N. Nicholson. *Improvements in ranges and stoves.* Dated April 7, 1862.

This invention consists in forming the fronts, panels, plates, and doors of kitchen ranges, and the panels of stoves, of enamelled iron. The invention also consists in means of fixing such enamelled iron, by forming frames in cast iron plates, and fitting the enamelled iron therein without screw or rivet fastenings; also in casting hollow projections in the cast iron plates, for the purpose of screwing therein taps or other necessary appliances. The enamelled iron plates have apertures formed therein, previous to being finished, to fit over such projections. The invention also consists in an improved form of hinge for the doors in kitchen ranges. The inventor casts a hollow boss with, and extending nearly the whole length of, the door, whereby great strength is obtained, and the use of detached hinges, rivetted in the usual manner, is dispensed with. This boss fits between two lugs on the plate to which the door is to be hinged, and a pin is passed through the lugs and boss. *Patent abandoned.*

987. T. Jackson. *Improvements in pianofortes.* Dated April 7, 1862.

For the purposes of this invention a spring is interposed between the end of the sticker or jack and the hammer butt, which spring, when employed in the action of an upright pianoforte, tends to bring back the hammer. At the front of the hammer butt there is an additional piece or projection which rests on the top of the jack or sticker when the hammer is away from the strings. The spring passes by preference into and works in a slit in the upper part of the jack or sticker, and it also passes into and works in a slit in the projection on the hammer butt, and the upper part of the spring presses against a pin passed across the slit in the projection on the hammer butt, so that when the hammer rises to strike the strings the spring is deflected, and has a greater tendency to bring back the hammer, and it prevents the hammer rebounding when it is back from the strings. *Patent completed.*

988. J. Watremez. *Improved apparatus for indicating a deficiency of water in steam generators.* Dated April 7, 1862.

This invention relates to a novel arrangement of apparatus for ensuring attention to the undue depression of the water level in steam boilers, the principle of action of the apparatus being to provide a way through the melting of an easily fusible plug for the escape of steam when the water in the boiler has fallen below a certain level, but until the water has reached that level to provide against the possible fusion of the plug. The invention cannot be described without reference to the drawings. *Patent completed.*

989. J. Carrington. *Improvements in paving stables and stable-yards.* Dated April 7, 1862.

In carrying out this invention the inventor proposes to make bricks with rounded tops and edges which, when brought together and cemented in their places, will produce a grooved surface, and will give the horse a good foot hold, and the edges being rounded the animal will not be liable to injure his haunches when lying down. As both the top and bottom edges of the bricks are rounded either side may be placed uppermost. The bricks should also be arranged diagonally, so that the grooves by running all in the same direction may be easily kept clean by means of a broom. *Patent abandoned.*

990. W. Steven. *Improvements in apparatus for moulding or shaping clay for bricks or other like articles.* Dated April 8, 1862.

In apparatus constructed with a modification of these improvements, the clay in a moderately plastic condition is put into a pug mill, resembling in construction those in ordinary use. The bottom of the pug mill is made flat or horizontal, and there is placed in close contact with its under surface a kind of sliding block, moulded in horizontal guides, and made to slide backwards and forwards across the pug-mill bottom by means of a connecting rod and crank. This crank may be conveniently formed or fitted on the central vertical shaft of the pug mill, this shaft passing through the bottom of the mill, and through a slot or elongated opening in the sliding block, whilst the connecting rod is jointed upon a pin projecting down from one end of the sliding block. The sliding block is formed with, say, four matrices or moulds, and there are four corresponding filling apertures in the pug-mill bottom, a pair on each side of the transverse horizontal central line. The pairs of matrices are situated so far apart in the sliding block that, when one pair is coincident with the filling openings, and receiving clay, the other piece is out clear of the mill delivering the bricks. As each matrix moves outwards from its filling opening, a compressing piston rises from below, and reaches its highest point just as the matrix finally quits the filling opening, and the material in the matrix is thereby compressed against the under side of the pug-mill bottom. The pair of compressing pistons at one end are mounted in a slide moving in its own guides beneath the sliding block, and actuated by catches on the sliding block in such a way as to move through only a part of the stroke of the latter. The pistons are elevated and depressed by means of levers on a shaft, or on studs beneath, the movement being caused simply by the horizontal motion of the slide twining the levers over through a limited angle. The other pair of compressing pistons are actuated by similar details at the other side of the machine. After the compression, the sliding block continues to move outwards, and the pistons descend until they clear the bottom of the block, whereupon the motion of the piston slide ceases, and the sliding block passes onwards until it completely clears them. The bricks are then discharged downwards from ont of the matrices by pistons, which are made to descend from above by means of levers actuated by the movement of the block, like the levers of the compressing pistons; these arrangements being, of course, repeated at both sides of the machine. For the purpose of preventing the clay from adhering to the bottom of the pug mill, to the sliding block, matrices, and other parts, provision is made for maintaining these parts at an elevated temperature, and this has at the same time the advantage of hastening the drying of the bricks. *Patent abandoned.*

991. J. Brown. *Improvements in protecting the bottoms and sides of ships, and other entirely or partially submerged surfaces.* Dated April 8, 1862.

This invention consists in protecting the bottoms and sides of ships, and other entirely or partially submerged surfaces, with planks or sheets of iron, which have been previously coated or covered with an enamel or glaze, either on one or both sides, such glazed or enamelled plates being caused to adhere to the sides and other portions of the vessel desired to be protected by means of a suitable cement, such as glue, or other adhesive material or mixtures. The plates may also be attached by means of nails, screws, rivets, or other suitable means, but the patentee prefers the employment of adhesive materials, as before mentioned, and more especially of that known as marine glue. The enamel or

glaze with which iron or metal plates, or sheathing to be employed for the above purpose are coated or covered, is such as will resist the action of salt or fresh water, and will not easily be detached from the iron or other metal. *Patent completed.*

992. W. BEARDMORE. *Improvements in steam rams for naval purposes.* Dated April 8, 1862.

Under one modification or arrangement this steam ram consists of an iron-plated vessel, which is actuated by steam power in the ordinary way. This vessel has fitted in it one or more steam rams, which may be arranged at the bow or stern, or along the sides, in manner similar to the heavy guns of a floating battery. Each of these rams are arranged in the form of a powerful horizontal rod, which forms a long sharp-pointed ram for perforating the sides of an enemy's ship or floating battery. These rods are intended to be made very heavy, and to be driven outwards by one or more engines, a sufficient amount of velocity or impetus being given to them, either by means of large fly wheels, by gearing, or any other convenient manner. *Patent abandoned.*

993. H. LEVINSTEIN. *Lustering silk.* Dated April 8, 1862.

This invention is not described apart from the drawings. *Patent abandoned.*

994. J. WHITEHOUSE. *Improvements in the manufacture of metallic door and other knobs, and the ornaments of the pillars of metallic bedsteads and other articles of like manufacture, and in attaching metallic mounts to china or earthenware knobs and ornaments, and roses for knobs.* Dated April 8, 1862.

The patentee claims making the necks of the said knobs from sheet metal by raising or pressing in dies, and spinning and fixing or casting in the said necks a socket in which the screwed or square spindle of the knob works, the said necks being joined to the bodies of the knobs in the usual way. Also, fixing the screw or axis in the necks made from sheet metal, by raising and spinning by means of zinc or other easily fused metal, or alloy cast into the said necks after the insertion of the screw or axis therein. Also, making the ornaments of the pillars of metallic bedsteads from sheet metal by the processes of stamping or pressing and spinning, and joining the parts together by pressure, the said ornaments, when required, having a screwed socket fixed or cast in them, as described. Also, certain improvements in attaching metallic mounts to china and earthenware knobs and ornaments, as described. *Patent completed.*

995. The Honorable W. E. FITZMAURICE. *An improved construction of plating for ships, batteries, and other structures used for war or other purposes* Dated April 8, 1862.

This invention consists in plating ships, batteries, and other structures in such a way that water is introduced and confined between two plates, thus forming a part of the resisting material against shot, shells, or any other projectile force, in contra-distinction to using solid plates of iron, steel, or other materials. For this purpose, the inventor uses cases of iron, steel, or other material filled with water, and so contrived as to be capable of being, by any convenient arrangement, emptied or refilled at pleasure. *Patent abandoned.*

996. C. P. CARTER. *An instrument for inserting photographic or other pictures into or removing them from between the "mounts" of photographic albums, or other flat spaces into which the fingers cannot be inserted.* Dated April 8, 1862.

This invention has more particularly for its object the obviation of the difficulty experienced in placing photographic pictures or "cartes de visite" between, or especially in removing them from, the spaces formed in the "mounts" of photographic albums, owing to these spaces between the back and front of the "mounts" being so narrow that the fingers cannot be inserted into them to lay hold of the pictures. To effect this operation with facility the inventor constructs an instrument resembling generally a pair of pliers, but with the jaws gradually thinned down to an edge at their extremity, and more or less widened out. The inner surface of the upper jaw is made quite smooth, so as not to damage the surface of the picture. These surfaces are furthermore so formed that, when quite closed, they meet only at their extremity, so that when opened slightly the space between them, corresponding with the ordinary thickness of a cardboard picture, is as nearly as possible parallel, by which, as also by the roughening of the lower jaw, the instrument will hold the picture inserted between it quite firmly. *Patent abandoned.*

997. F. W. BREAREY. *Improvements in medicated cups or vessels for drinking purposes.* Dated April 8, 1862.

The first of these improvements consists in the formation of a cup or vessel upon a combined medicating principle, in and by which the medicinal qualities of steel, iron, ironide, or other suitable metal, metals, metalline, or their oxides, or mineral or mineraline, simple or compounded, and the tonic or aromatic qualities or medicinal virtues of bitter wood, bark, or other vegetable matter, are combined and imparted simultaneously to the water or other liquid contained therein. The drinking vessels formed upon this principle the patentee denominates "The Improved Medicated Steel Bitter Cup." The second improvement consists in the formation of a similar cup or vessel, the bowl of which is formed wholly of steel metal or mineral (antimony excepted), otherwise than when used as hereinafter described, or of metals or minerals compounded or alloyed with antimony, the inner surface of such bowl or cup, or vessel, being oxidised by the application of acids or ammonia, in and by which the water or other liquid contained therein is medicated by being impregnated with the medicinal qualities or virtues of the said metals or minerals. The drinking vessels formed upon this principle he denominates "The Improved Medicated Mineral Cup." The third improvement consists in the formation of similar cups and vessels in and by which the principle of galvanic action, obtained either in combination with the medicinal qualities above-mentioned, or otherwise. The drinking vessel formed upon this principle he denominates "The Improved Medicated Galvanic Cup." In applying the first-mentioned improvement, he makes a cup or other vessel in two or more parts, one portion being composed of metals or mineral, simple or compounded, and oxidised on the inner surface, and the other portion composed of wood or other vegetable matter possessing in itself the required bitter tonic or aromatic or other medicinal qualities, or impregnated or saturated therewith. The wood or vegetable portion is fitted to the metal or mineral portion so as to be water-tight when joined together. The water or other liquid then medicated, is then poured into the cup or vessel, where it comes in contact with, and is acted upon by, the oxidised surface or surfaces of the metal or mineral portion, and where it also comes in contact with, and is acted upon by, the surface or surfaces of the wood or vegetable portion; and the combined medicinal qualities of the metal or mineral, and the wood, bark, or vegetable portions are thus simultaneously imparted thereto. *Patent completed.*

998. E. H. C. MONCTON. *Improvements in timekeepers.* Dated April 8, 1862.

This invention consists, firstly, in novel methods of regulating the admission of air or gas at either or both ends of the tubes of atmospheric or gas clocks by means of stop cocks or screw cocks of various constructions, and of any suitable material attached to them, by means of which, by merely turning the screw, the ascent or descent of the air can be regulated to the greatest nicety, and thus a perfect timepiece can be obtained. *Patent completed.*

999. J. JAQUES, JUN. *Improvements in the instruments used in the game of croquet.* (A communication.) Dated April 8, 1862.

For the purposes of this invention, in order that the players may know which (if any) of the players balls have been played through any of the several hoops or arches, a marker for each player is used which is formed in a suitable manner to admit of its being readily placed on and removed from the hoops or arches, so that a player having played his ball through an arch or hoop will place his marker thereon, where it will remain till he has played his ball through another hoop or arch, when he will remove his marker from the hoop or arch previously marked, and place it on the hoop or arch last played through. The form of marker preferred, although the same may be varied, consists of a plate of elastic metal, or other suitable material, bent in the middle, but not so that the two parts may come close together; on the contrary, a space is left between the two surfaces somewhat less than the thickness of the hoops or arches, so that a marker when passed down on a hoop or arch will, by its elasticity, retain its position by slight pressure. The markers may be of different colours or be numbered, or have devices thereon in order to indicate the players to whom they belong, and they may also be made to indicate the direction in which the balls of the players have been played through the hoops or arches. Heretofore the mallets employed in playing the game of croquet have had cylindrical heads, or heads of a circular transverse section; and part of this invention consists in forming the under surface of the head of a croquet mallet of a curved convex shape, with upright or nearly upright sides and ends, the sides being made somewhat hollow or concave from end to end. The two ends of the head of a mallet are of different dimensions; the larger end is of a rectangular form, somewhat wider than it is high, and the other or smaller end is also of a rectangular form, but of considerable width as compared to its height, the object being that this end of the mallet should be used by a player when striking his ball at the time his foot is placed thereon, which he is enabled to do with more certainty and advantage than when using a mallet with a head having a cylindrical form, or otherwise of a circular transverse section. *Patent completed.*

PROVISIONAL PROTECTIONS.

Dated July 15, 1862.

2035. T. G. Ghislin, Hatton-garden, importer. Improvements in the treatment or preparation of British and foreign algæ, and the application of the same to various branches of the arts and manufactures.

Dated July 22, 1862.

2080. A. Fournier, upholsterer, 18, Maddox-street. Improvements in the manufacture of easy chairs, seats for railway and other carriages, and other kinds of seats and mattresses.

Dated July 30, 1862.

2167. W. Norman, Manchester, cabinet maker. Improvements in tables and drawers or other sliding receptacles.

Dated August 1, 1862.

2186. W. E. Newton, 66, Chancery-lane, civil engineer. Improvements in projectiles for ordnance and small arms, and in the wads or sabôts to be used therewith. (A communication.)

Dated August 8, 1862.

2220. J. Sirou, Castelsarrazin, Tarn et Garonne, France, contractor of public works. A new medicinal preparation for internal and external application.

Dated August 16, 1862.

2311. S. A. Bell, Epping-villas, Stratford, lucifer-match manufacturer, and T. Higgins, Carriaco-terrace, Bow, tornographer. Improved apparatus for dipping lucifer matches.

Dated September 6, 1862.

2467. W. A. Richards, Chester-cottage, Cornwall-place, Holloway, commercial clerk. An improved fastening for purses, pocket books, bags, cigar cases, books, wearing apparel, jewellery, and other articles.

Dated September 16, 1862.

2542. W. Clark, 53, Chancery-lane, engineer. Improvements in the treatment of peat and peat tar for the production or manufacture of various products, and in apparatus for the same. (A communication.)

Dated September 19, 1862.

2571. J. B. Giertz, Great St. Helen's, City. Improvements in gas burners or jets.

2574. J. Imray, Bridge-road, Lambeth, engineer. Improvements in apparatus for telegraphing and signalling by means of electricity. (A communication.)

Dated September 23, 1862.

2591. J. Mapple, Newman's-place, Kentish Town, and D. Mapple, 3, Queen's-road, Homerton New Town, telegraph and clock makers. Improvements in telegraphic apparatus.

Dated September 27, 1862.

2634. M. Henry, 84, Fleet-street. Certain new and improved applications of petroleum and its products, certain agents produced by combining the same with other substances, and certain modes of treating caoutchouc, gutta-percha, and their compounds, and substances similar thereto. (A communication.)

Dated September 30, 1862.

2654. A. Prince, 4, Trafalgar-square, Charing-cross. Improvements in the manufacture of varnish, printing ink, paint, and printing colours. (A communication.)

Dated October 1, 1862.

2660. E. Lord, Rawtenstall, Lancaster, overlooker. An improvement in power looms for weaving.

Dated October 2, 1862.

2663. W. H. Ward, New York, and 59, Packington-street, London, N. Improvements in night, day, and fog signals, and the means for effecting the same.

Dated October 3, 1862.

2672. W. Clark, 53, Chancery-lane, engineer. Improved atmopsheric toy pistols and guns. (A communication.)

Dated October 4, 1862.

2684. J. M. Cabirol, 17, Rue du Faubourg, Montmatre, Paris, submarine engineer. A new or improved submarine lamp.

2688. W. Clark, 53, Chancery-lane, engineer. Improvements in the means of preserving goods from fire, and in apparatus for the same. (A communication.)

Dated October 6, 1862.

2693. T. Keech, New York. Improvements in floating batteries. (A communication.)

Dated October 7, 1862.

2711. J. K. Hampshire, Whittington, Derby, civil engineer. Improvements in apparatus or machinery for washing coal, coal slack, and other mineral substances, and separating foreign particles therefrom.

2712. J. Beale, Hope-street, Maidstone, gentleman, and M. A. Beale, Upper Brunswick-terrace, Barnsbury. Improvements in the preparation or manufacture of manure.

Dated October 8, 1861.

2714. C. F. Terry, Sheffield, accountant. Improvements in machinery for propelling vessels.

2715. D. Nickols, Manchester, engineer and manufacturer. Improvements in machinery or apparatus for measuring and registering lace and other similar articles.

2716. W. C. Burden, Leicester, musical instrument maker. Improvements in mechanism for giving the pitch or tone required in tuning musical instruments, and also the key note of vocal music.

2717. T. Ratcliffe, Colne, Lancaster, manager. Certain improvements in looms for weaving.

2718. P. Clavel, Paris, France, chemist. Improvements in the treatment of violet colours derived from coal tar oils.

2719. J. R. Harris, Goldington-crescent, St. Pancras-road, Middlesex, house decorator. Improvements in propelling vessels.

Dated October 9, 1862.

2721. H. Dullens, 13, Little Britain. An improved runner or fastening for umbrellas, parasols, sun shades, and other like articles.

2722. J. Maurice, 3, Langham-place, Regent-street, dentist. Improvements in steering ships or vessels, and in the apparatus to be employed for that purpose.

2723. W. Bush, Tower-hill, civil engineer. Improvements in cannon and small arms.

2724. C. N. Wilson, Batley Carr, near Dewsbury, rag-merchant. Improvements in rag machines.

2726. J. H. Johnson, 47, Lincoln's-inn-fields, gentleman. Improvements in the manufacture of paints or pigments. (A communication.)

2727. R. Hammond, 4, Trafalgar-square. Improvements in armour for ships of war.

2728. A. V. Newton, 66, Chancery-lane, mechanical draughtsman. Improved machinery for breaking and cleaning flax, hemp, and other like fibrous substances. (A communication.)

2729. J. B. Palser, Crown Hotel, Holborn, paper maker. Improved apparatus for manufacturing paper pulp and recovering the alkali used in such manufacture.

2730. G. Simons, 27, Place du Théatre, Liege, Belgium, manufacturer. Improvements in the manufacture of plates, rods, axles, tyres, and other articles that are required to be partly of iron and partly of steel.

Dated October 10, 1862.

2731. L. Hosch, commercial agent, 9, Laurence Pountney-hill, Cannon-street. An improvement in the mode of constructing travelling trunks and portmanteaus.

2732. W. and S. Scholefield, Ashton-under-Lyne, Lancaster, manufacturing jewellers. Improvements in apparatus for cutting button holes and other similar purposes.

2733. R. E. Green, Accrington, Turkey red dyer, and J. Cockcroft, machine printer. An improved amalgamation of materials forming a substance suitable for printers' blankets, conductors used in paper making, packings for joints, and similar purposes.

2734. G. Baguley, Hanley, Stafford, china manufacturer, and H. Greener, Sunderland, flint glass manufacturer. An improved construction of insulator for telegraph wires.

2735. J. Lowe, Claremont-place, Old Kent-road, machinist, and J. Harris, Ess Hill House, Newton Abbot, gentleman. An improved construction of propeller.

2736. H. A. Marinoni, Rue de Vaugirard, Paris, engineer. Improvements in apparatus for fixing type in the chases.

2737. W. C. Edge, Clerkenwell. Improvements in velocipedes.

2738. D. S. Sutherland, Crosby-square, City, civil engineer. Improvements in constructing beams, girders, bridges, and viaducts.

2739. W. Weallens, Newcastle-upon-Tyne, engineer. Improvements in surface condensers for marine and other engines.

2740. T. Anderson, Glasgow, mechanic. Improvements in the construction of ships or vessels.

Dated October 11, 1862.

2741. J. J. Shedlock, 63, Cambridge-street, Pimlico. Improvements in gas meters.

2742. E. J. Franklin, Birmingham, manufacturer. A combined spring tape measure, needle case, and pin cushion.

2743. A. Vennedy, Swan-yard, Shoreditch, manufacturer. An improved composition for covering and forming the tips of umbrellas and parasols, also applicable to covering the ribs and stretchers of same.

2744. R. A. Brooman, 166, Fleet-street, patent agent. Improvements in breech-loading firearms. (A communication).

2745. W. Catchpool, 355, Goswell-road, miller. Improvements in fire escapes.

2746. J. Durant, 3, Stangate-street, Westminster, mechanical engineer. Improvements in the form and construction of chimney tops, or appliances for surmounting chimneys.

2747. T. Bouch, Edinburgh, civil engineer. Improvements in machinery or apparatus for charging or filling cartridges.

2748. A. V. Newton, 66, Chancery-lane, mechanical draughtsman. Improvements in evaporating apparatus applicable for the manufacture of sugar. (A communication.)

2749. A. V. Newton, 66, Chancery-lane, mechanical draughtsman. Improvements in sewing machines. (A communication.)

Dated October 13, 1862.

2750. S. Chatwood, Liver Safe Works, Bolton, safe manufacturer. Improvements in and connected with fire and thief proof depositories, and locks or fasteners connected therewith, parts of which improvements are also applicable to other purposes of security.

2751. G. and A. Harvey, Glasgow, engineers. Improvements in boring machinery.

2753. G. Haseltine, Fleet-street, American barrister-at-law. Improvements in "jacks" and screw nuts for attaching thills and poles of waggons and other vehicles to the axle trees of the same. (A communication.)

2754. C. McCarthy, New York. Improvements in automatic safety valves.

2755. W. Loeder, 1, New Broad-street, merchant. An improved projectile to be used with ordnance or firearms of any calibre. (A communication.)

2756. C. Thomas, Bristol, soap manufacturer. Improvements in the manufacture of silicate of soda or silicitate of potash, and in the manufacture of artificial stone.

2758. J. Gumbley, Llantrissent, Glamorgan, contractor. An improved break for vehicles travelling on common roads.

2759. A. I. Mahon, 25, Leinster-square, Rathmines, Dublin, engineer. Improvements in propellers and paddle floats, also applicable to the raising and forcing of water or other fluids.

Dated October 14, 1862.

2761. S. Smith, 204, High Holborn, engineer. Improvements in kettles, saucepans, and boilers for domestic and other purposes.

2762. F. G. Grice, West Bromwich, Stafford, manufacturer. An improvement or improvements in the manufacture of nuts for screwed bolts, and in machinery to be employed in the said manufacture.

2763. E. Suckow, and E. Habel, Manchester, machinists. Certain improvements in machinery or apparatus for preparing, spinning, and doubling cotton and other fibrous materials.

2764. H. Bridson, Bolton-le-Moors, bleacher and finisher, and J. Alcock, millwright. Improvements in machinery for folding, measuring, and hooking woven fabrics.

2765. E. Barlow, Bolton-le-Moors, machine maker, and J. Clough and F. Hamilton, foremen. Certain improvements in machinery for driving cotton gins, and for preparing and combing cotton and other fibrous substances.

2767. C. Harratt, Hornsey-lane, Highgate. Improvements in ships' masts.

2768. D. and C. J. Reid, Grey-street, Newcastle-upon-Tyne. Improvements in the manufacture of cases for watches and other pocket time-keepers.

2769. M. Cartwright, Hoxton, dentist. Improvements in plates for artificial teeth.

2770. R. A. Brooman, 166, Fleet-street, patent agent. Improvements in apparatus for carburetting gas. (A communication.)

2771. R. A. Brooman, 166, Fleet-street, patent agent. Improvements in dressing millstones, and in materials employed therein. (A communication.)

2772. E. H. C. Monckton, 5, Thurloe-place, South Kensington, esquire. Improvements in coils of induction, and in obtaining and applying power by means of electro-magnetism.

2773. O. J. and J. Showell, Manchester, surveyors. Improvements in the construction of glass roofs and roof lights.

2775. J. H. Johnson, 47, Lincoln's-inn-fields, gentleman. Improvements in sewing machines. (A communication.)

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

1768. T. Williams, and H. Cox. Churns.

1785. S. H. Huntly. Construction of furnaces.

1789. A. W. Makinson. Locomotive and stationary engines.

1792. M. Turner, and E. T. Loseby. Small arms and ordnance.

1808. R. Stansfield, and J. Dodgeon. Looms.

1816. J. B. T. Detuncq. Treating flax or hemp.

1822. J. W. Taylor. Regulating and indicating the flow and pressure of fluids.

1825. A. Warner. Manufacture of pigments or paints from certain refuse materials.

1826. G. Gray, and D. Cuningham. Casting or moulding metals.

1831. G. Simpson. Working, boring, and mining or excavating tools, and mine and other pumps.

1836. A. F. Maigron. Manufacture of tow or oakum.

1837. J. H. Redstone. Construction of boilers. (A communication).

1852. T. Desgrandschamps. Steam engines.

1859. M. A. F. Mennons. Steam boiler furnaces. (A communication).

1871. W. Clark. Frame for holding photographic pictures. (A communication).

1889. A. H. Martin. Apparatus employed in weaving.

1896. J. Garnier. Ordnance.

1901. J. Tatham. Preparing, spinning, doubling, and winding fibrous materials.

1917. R. A. Brooman. Construction of blast furnaces. (A communication).

2058. A. B. Brown. Steam engines and boilers.

2167. W. Norman. Tables and drawers or other sliding receptacles.

2184. J. E. Marsh. Metal rivets.

2186. W. E. Newton. Projectiles for ordnance and small arms. (A communication).

2311. S. A. Bell, and T. Higgins. Dipping lucifer matches.

2468. C. W. Williams. Steam boilers.

2569. J. Bouvet. Closing or sealing tin preserve boxes.

2628. J. Milner, R. D. Milner, and F. Hurd. Preparing wool, flax, and other fibrous substances.

2659. B. Donkin. Bearings for shafts, axles, pivots, and sliding surfaces. (A communication.)

2663. W. H. Ward. Night, day, and fog signals.

2667. G. J. Firmin. Treatment of certain salts of potash and lime.

2677. T. Greenwood. Machinery for cutting staves.

2693. T. Keech. Floating batteries. (A communication.)

2708. A. Forbes. Connecting together parts of vessels formed of tin plate.

2709. J. D. Welch, and A. P. Welch. Blocking and pressing hats and bonnets.

2717. T. Ratcliff. Looms.

2736. H. A. Marinoni. Fixing type in the chases.

2754. C. McCarthy. Automatic safety-valves.

2767. C. Harratt. Ships' masts.

The full titles of the patents in the above list can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list who have given notice of their intention to proceed, within twenty-one days from the date of the *Gazette* in which the notice appears, by leaving at the Commissioners' office particulars in writing of the objection to the application.

LIST OF SEALED PATENTS.

Sealed October 24, 1862.

1210. R. C. Mansell.
1211. P. R. Drummond.
1214. J. Elder.
1216. J. Aspinall.
1220. W. Hale.
1221. W. Fisken.
1222. L. McLachlan.
1226. T. U. Brocklehurst.
1234. H. W. Hart.
1237. A. Lester.
1243. R. Vaile.
1246. H. F. Wells.
1250. S. W. Newington.
1251. E. Clark.
1252. W. Clark.
1253. J. Ross.
1256. W. L. Tizard.
1257. D. M. Childs.
1258. D. M. Childs.
1259. D. M. Childs.
1260. E. B. Wilson.
1264. E. Moore.
1265. A. Travis and B. Travis.
1269. G. Davies.
1271. J. Maiden.
1277. J. M. Carter.
1278. A. Prince.
1279. W. Staufen.
1280. J. L. Norton.
1281. J. M. Napier.
1284. H. Willis.
1286. W. T. Loy.
1293. W. Bodden and W. Mercer.
1318. J. Fowler.
1322. C. Schlickeysen.
1328. H. Allman.
1339. E. B. Wilson.
1354. W. Clark.
1362. T. H. Hopwood.
1376. W. Riddle.
1431. T. Buckney.
1519. M. A. F. Mennons.
1894. M. A. F. Mennons.
1971. J. M. Gille.
2006. M. A. F. Mennons.
2105. T. Lemaistre.

PATENTS ON WHICH THE STAMP DUTY OF £100. HAS BEEN PAID.

2359. A. Parkes.
2466. W. Gardner.
2377. J. Rives.
2392. T. B. Sharp, and R. Furnival.
2404. J. Hands.
2399. S. O'Regan.

PATENTS ON WHICH THE STAMP DUTY OF £50 HAS BEEN PAID.

2410. G. T. Bousfield.
2416. W. Fox, and J. Willis.
2417. R. A. Brooman.
2594. T. D. Perkin.
2460. H. Phillips, and J. Bannehr.
2413. J. Avery.
2450. J. Armour.
2474. C. Stannet.
2477. J. A. Turner.
2458. P. R. Hodge.
2461. R. A. Brooman.

THE
MECHANICS' MAGAZINE.

LONDON, FRIDAY, NOVEMBER 7, 1862.

LIVES OF THE ENGINEERS.*

Bid harbours open, public ways extend;
Bid temples, worthier of God, ascend;
Bid the broad arch the dang'rous flood contain,
The mole projected, break the roaring main;
Back to his bounds their subject sea command,
And roll obedient rivers through the land.
These honours Peace to happy Britain brings;
These are imperial works, and worthy kings.
POPE.

WHEN, some twelve months since, it fell to our lot to review the two first volumes of the "Lives of the Engineers," we took the opportunity of advising Mr. Smiles to lose no time in continuing the great work upon which he had, with so much success, entered. That advice, we are pleased to find, has been acted upon, and the result is a third volume, which now lies before us. No doubt the task of producing this was comparatively an easy one, because the author had already, in his well-known memoirs of George Stephenson, travelled over the ground which is again explored in the work under notice. In his preface to the third volume of the "Lives of the Engineers," which is exclusively devoted to the illustrious father and son, George and Robert Stephenson, Mr. Smiles tells us very truly that, "although it is "unusual to embody two biographies in one "narrative, yet that in the case of the Ste- "phensons such a combination is peculiarly "appropriate, the life and achievements of the "son having been in a great measure the com- "plement of the life and achievements of the "father. The care with which the elder "Stephenson, while occupying the position of "an obscure workman, devoted himself to his "son's education, and the zeal with which the "latter repaid the affectionate self-denial of "his father, are among the most effective il- "lustrations of the personal character of both." Indeed, it would have been unwise to have adopted any other course than the one which Mr. Smiles thus sketched out for himself, and we shall now endeavour to ascertain, and to record the amount of success which has attended our author in dealing with the two subjects of his third volume. In the first chapter of the work an historical account of Newcastle-upon-Tyne, usually called the birthplace of George Stephenson, from the period of the Roman occupation of Britain down to the middle of the last century, is given, as well as a description of the physical peculiarities of the neighbouring country at the latter period. The following graphic picture of the Newcastle of to-day will be recognized by those who have visited it:—"Newcastle is, in many respects, a town of "singular and curious interest, especially in its "older parts, which are full of crooked lanes "and narrow streets, wynds, and 'chares,' "formed by tall, antique houses, rising tier "above tier along the steep northern bank of "the Tyne, as the similarly precipitous streets "of Gateshead crown the opposite shore. A "dense cloud of smoke continually hangs over "the place, almost obscuring the sun's light. "North and south the atmosphere is similarly "murky, and all over the coal region, which "extends from the Coquet to the Tees, about "fifty miles, the surface of the soil exhibits "the signs of extensive underground workings. "In every direction are to be seen swollen heaps "of ashes and refuse, coals and slag, the "rubbish of old abandoned pits, and the pump- "ing engines and machinery of new. As you "pass through the country at night, the earth "looks as if it were bursting with fire at many "points; the blaze of coke ovens, iron furnaces, "and coal heaps, reddening the sky to such a "distance that the horizon seems to be a glow- "ing belt of fire." The necessity which, at a very early period, existed for facilitating the transport of coals from the pits to the shipping stations, naturally excited the inventive faculties of those who were employed in the work. In the first instance, the most laborious of all modes of conveyance was adopted, that of carrying the coals in panniers on the backs of men to the boats. This yielded to the employment of sacks on horses' backs for the same purpose. Then carts and tramways of flat stones were used. A local writer, of about the middle of the seventeenth century, says: "Many thousand people are engaged in this "trade of coals. Many live by working of "them in the pits, and many live by conveying "them in waggons and wains to the river "Tyne." Other means of transport are referred to by Mr. Smiles, and among them, wooden trucks of peculiar construction, and which may be considered the germ of the modern railroad. The first iron rails are supposed to have been laid down in 1738. This cast-iron road was denominated a "plate-way," from the plate-like form in which the rails were cast.

It is shown by the books of the Coalbrookdale Iron Works, in Shropshire, that five or six tons weight of rails were cast at that place, as an experiment, on the suggestion of Mr. Reynolds, one of the partners, and they were shortly after laid down to form a road. With a commendable amount of research and inquiry, Mr. Smiles has endeavoured to trace the rise and progress of the railway prior to the time when George Stephenson perfected, so to speak, its development, and has preserved from oblivion the names of some of the predecessors of the great engineer. Some of the anecdotes in relation to these modest pioneers, who may be literally said to have "paved the way" for the introduction of modern railroads, are at once interesting and instructive. We learn, for example, that "in 1776, a cast-iron tram- "way was laid down at the Duke of Norfolk's "Colliery, near Sheffield. The person who "designed and constructed this coal line was "Mr. John Curr, whose son has erroneously "claimed for him the invention of the cast- "iron railway. He certainly, however, "adopted it early, and thereby met the fate "of men before their age. His plan was "opposed by the labouring people of the "colliery, who got up a riot in which they tore "up the road and burnt the coal-staith, whilst "Mr. Curr fled into a neighbouring wood for "concealment, and lay there *perdu* for three "days and nights, to escape the fury of the "populace." The plates or rails of this line were, according to an illustration, cast with flanges on their inner edges to guide the wheels along it. By these gradual steps was progress made in the formation of railways, and there is no doubt that the locomotive was the result of similarly gradual improvements. "The "locomotive is not the invention of one man," said Robert Stephenson, once at Newcastle, "but of a nation of mechanical engineers."

The different contrivances for raising coals from the pits, the application subsequently of Newcomen's engine to that purpose, and some interesting glimpses of pit life, bring us to the end of what may be termed the introduction to the third volume of the "Lives of the Engineers," and to the birth time of the elder Stephenson. At the colliery village of Wylam, about eight miles west of Newcastle-upon-Tyne, there lived, in 1781, and in a house still standing, Robert Stephenson, or "Old Bob," as his neighbours called him, and his wife Mabel. They were a respectable couple, careful and hard-working; they belonged, indeed, as Mr. Smiles justly remarks, "to the ancient "and honourable family of workers—that ex- "tensive family which constitutes the back- "bone of our country's greatness, the "common working people of England." Such were the parents of George Stephenson. On the 9th of June, 1781, the latter came into existence, and the apartment in which he was born is now what it was then, "an ordinary "labourer's dwelling; its walls are un- "plastered, its floor is of clay, and the bare "rafters are exposed overhead." Robert Stephenson, the father of George, and of five other children, whose births were duly recorded on the fly leaf of the family Bible, though not on the parish books, was a tall gaunt man. A Wylam collier gave the following odd description of him and his wife:—"Geordie's "fayther war like a peer o' deals nailed the- "gither, an' a bit o' flesh i' th' inside; he war "queer as Dick's hatband—went thrice aboot, "an' wudn't tie. His wife Mabel war a "delicat' boddie, an' varry flighty. They war "an honest family, but sair hadden doon i' th' "world." Into other peculiarities related as pertaining to "Old Bob," it is not desirable here to enter, but the following glimpse of the early days of George Stephenson is worth transcribing:—"The boy led the ordinary life of "working men's children. He played about "the doors; went birds'-nesting when he "could; and ran errands to the village ". . . At home he helped to nurse—and "that with a careful hand—his younger bro- "thers and sisters. One of his duties, too, was to "see that the other children were kept out of "the way of the chaldron waggons, which "were then dragged by horses along the "wooden tramroad, in front of the cottage "door. This waggon-way was the first in the "Northern district, along which the experi- "ment of a locomotive engine was tried. But "at the time of which we speak, the locomo- "tive had scarcely been dreamt of in England "as a practical working power." Eight years of the future engineer's life was spent in this way, and then his father, having obtained employment as a foreman, at Dewley Burn Colliery, removed with his family to that place. The natural shrewdness of "Geordie" frequently showed itself conspicuously at this early period of his life, and some amusing instances of the fact are recorded by Mr. Smiles. But it was necessary that the boy's talent, and strength, such as it was, should be devoted to the purpose of assisting in the maintenance of the household, or at least, in supporting himself. His first actual employment was to herd the cows of a widow, occupying a farm-house in the neighbourhood, and to keep them off the track of the coal waggons. Two-pence per day was the munificent return for this humble service. Such spare time as could be got was devoted, with his chosen companion, "Bill Thirlwall," to the erection of clay engines and Lilliputian mills. They even proceeded to make a miniature winding machine, and the apparatus was erected upon a bench in front of Thirlwall's cottage. These amusements are worthy of note, because they betoken the bent of that mind, which was afterwards to conceive projects of so much importance to the community. Thirlwall, it may be said, in passing, afterwards became a workman of repute, and filled the office of engineer at Shilbottle, near Alnwick, for a space of twenty or thirty years.

* Lives of the Engineers, with an Account of their Principal Works; comprising also a History of Inland Communication in Britain. By Samuel Smiles. With numerous Portraits and Illustrations. Vol. III. George and Robert Stephenson. London: John Murray, Albemarle-street. 1862.

Subsequently, George Stephenson worked in the fields, leading the horses at the plough, hoeing turnips, and making himself "generally "useful," at the advanced wages of 4d. per day! His ambition, however, was not satisfied. He desired to be employed at the colliery where his father worked, and this wish was soon gratified. At Dewley Burn he was first set to work as a "corfbitter" or "picker," his duty being to clear the coal of stones, bats, and dross. Sixpence per day was now paid him, and at length his promotion to the driving of the "gin-horse" led to the increased allowance of eightpence per day. Black Callerton Colliery was the scene of his next operations, and in this he also drove the gin. One of the old residents of Black Callerton, who well remembered "Geordie," described him to Mr. Smiles at the period named as a "grit growing "lad with bare legs an' feet," adding that he was "very quick-witted and full of fun and "tricks." At fourteen years of age, Stephenson was appointed assistant fireman at Dewley Burn Colliery, and his pay at this time was one shilling per diem. The working out of the pit at last brought this engagement to a close, and "Old Bob" and his family were compelled to change their quarters.

At Jolly's Close, near the village of Newburn, the Stephensons took up their next abode, and this was humble enough, for they occupied "a cottage of one room," and "in which the father, mother, four sons, and two daughters lived and slept." Colliery occupations of one kind and another were followed at this place by the various members of the family, until George was sent, with a comrade, named Coe, to work a pumping engine near Throckley Bridge. While employed at this place, Stephenson's wages were raised to twelve shillings per week, an event which elated him much. "On coming out of the foreman's office, on the Saturday evening on which he had received the advance, he announced the fact to his fellow-workmen, adding, triumphantly, 'I am now a made man for life!'" It was not, fortunately for the world, the disposition of George Stephenson to remain content at any one point of his career. "Excelsior" was his motto, and he knew that apathy was not the means for effecting advancement and self-elevation. Appointed as "plug-man" at a new pit some short distance from Newburn, he took an opportunity of studying the working of the steam engine there. This engine, indeed, "became a pet with him, and he never wearied of watching and inspecting its movements."

One great drawback, Stephenson began now to find was, his lack of education. Although eighteen years of age, he was unable to read. Having once become conscious of the disadvantages under which his ignorance of "bookish theory" placed him, he was not long in setting about removing them. "His "first schoolmaster was Robin Cowens, a "poor teacher in the village of Walbottle. . . ." Robin's teaching cost threepence a week, and by its aid, Stephenson soon learnt to read. He also practiced "pothooks," and at the age of nineteen, was proud to write his own name. In 1799, Andrew Robertson, a Scotch dominie, set up a night school at Newburn, and during the winter of that year one of his most persevering pupils in the "figuring" department, was George Stephenson. The post of brakesman was next given to the future engineer, and it was while engaged in this occupation that he devoted his spare time to shoe-mending, and afterwards to shoe-making. These pursuits were probably followed with more avidity from the fact that he had now formed an attachment for a young woman, named Fanny Henderson, a servant in the farm-house, in which he lodged, and desired to save money wherewith to marry and establish a home for himself. An amusing story is told of his soleing the shoes of his sweetheart, and making a "capital job" of them. Out of his earnings by shoe-mending, Stephenson contrived to save "his first guinea," and of this feat he was justly proud.

A quarrel with a pitman—a "roistering "bully, who was the terror of the village of "Black Callerton," led Stephenson to engage in a pugilistic encounter, and great was the excitement, when it was known that this event was to take place. His antagonist, Ned Nelson by name, was no novice at fighting, and hence it was supposed that Geordie would be severely punished in the coming encounter. "On the evening of the day appointed," says Mr. Smiles, "after "George had done his day's labour, he went "into the Dolly Pit-field, where his already "exulting rival was ready to meet him. "George stripped and 'went in' like a prac-"tical pugilist, though it was his first and last "fight. After a few rounds, George's wiry "muscles and practised strength enabled him "severely to punish his adversary, and to "secure an easy victory. This circumstance "is related in illustration of Stephenson's "pluck and courage, and it was characteristic "of the man." At twenty-one years of age an offer was made to George to take charge of the engine at Willington Ballast-Hill. This he accepted, and at the same time made "an "offer" himself to Fanny Henderson, and which she did not decline. On the 28th of November, 1802, the wedding took place at Newburn church, and a cottage dwelling received the newly-married pair.

While at Willington Mr. William Fairbairn, of Manchester, made the acquaintance of Stephenson, and the friendship thus begun lasted for many years afterwards. At Willington, too, Stephenson's only son Robert was born on the 16th of October, 1803, and the child was from the first a great favourite with his father, whose evening hours were made happier by his presence. After working about three years as a brakesman at the Willington machine, George Stephenson was induced to take a similar post which presented itself at the West Moor Colliery at Killingworth. "The village of Killingworth is about "seven miles north of Newcastle, and is one of "the best known collieries in the district." Thither went our "hero,"—such he may be truly called, for none have ever more vigourously and manfully carried themselves in the battle of life than he—in the year 1804. Scarcely had he reached his new abode, however, when the shadow of death fell across his threshold—his wife died. "It was a terrible blow to him, and he "long felt the bereavement." Other changes were—perhaps fortunately, for they diverted his mind from domestic sorrows—in store for Stephenson. He received an invitation to proceed to Montrose, in Scotland, and to superintend the working of one of Boulton and Watts' engines. "Having left his boy in the care of "his father and mother, he set out upon his "long journey to Scotland on foot, and with "his kit upon his back."

At Montrose his mechanical abilities developed themselves, and his management of certain repairs of the pumping machinery brought him much credit. At the end of twelve months he returned to Killingworth, with a clear saving of £28 in his pocket. On his way home, on foot, Stephenson was hospitably entertained by an honest couple, who would not hear of any recompense for their good offices. Later in life, when the sun of fortune shone brightly upon the 'erstwhile foot-sore, and weary traveller, he sought their cottage again, and when he left it they may have been reminded of the old saying, that we may "sometimes entertain angels unawares."

We shall return to this subject in our next number.

JURY REPORTS—CLASS VIII.

As our readers will have seen, we printed in our three preceding numbers one of the "Reports of the Juries," International Exhibition, this particular one being in Class VIII., machinery in general. The whole of these Jury reports were promised to the public for August last; some disjointed, meagre little pamphlets made their appearance about the beginning of October. So much for the punctuality of the performance. We feel it to be our duty, however, as we have copied this particular report, to make a few observations about its contents to our readers.

In No. 3 of "General Explanations and Remarks," the Jury say, that if they had not been prevented by clause 5 of the decisions of the Commissioners, they (the Jury) would have awarded medals to—1801, N. and L. R. Bodmer, safety valves for steam boilers; 1955, J. Penn and Sons, marine engines, and parts of marine engines. We should like to know in what respect these two members of the Jury are behind hand in recompense to those exhibitors that have been dignified with an, as yet, unfulfilled promise of a medal? These two jurors are much better off than an exhibitor; say, from California; for while they get all the honour (?) of a public mention, they have not to pay any freight for an ugly piece of pewter, with an inartistic design. We do not suppose that the unlucky guarantors will send the medals out free.

Nos. 5 and 8 of these "general explanations "and remarks" form a mere tirade of excuses for shortcomings; as the French very truly say, "Qui s'excuse, s'accuse."

No. 11. is a complete repetition in almost the very same words, of a part of the speech of Mr. Fairbairn to the mechanical section of the British Association of Cambridge. In pages 3 and 4, the observations about the prevalence of the horizontal form of engine also appear in Mr. Fairbairn's speech. To say the least these are very remarkable and curious coincidences.

In Subdivision I., Section III., the marine engine of the Mediterranean Company (France) is mentioned as the exception to the general use of the link motion for reversing. It just happens that there is another marine engine in the Exhibition, a Swedish one, also reversing without a link.

Page 6, Section VI., some water-pressure engines are generously accredited to Messrs. Smith, Beacock, and Tannett, of Leeds. We believe that these gentlemen never made such an apparatus in the whole course of their career.

Section VII., "vacuum power-engine." We agree entirely with the Jury in the sapient remark they make under this title. They say, "that they could find no engines to which the "above description seemed to be applica-"ble."

In Subdivision IV., Section I., driving bands, and some engine governors, are appropriately (!) classed together; we presume, however, by a fault of the printer. Under this same section, a governor of Mr. Schiele is alluded to in terms that would lead one to conclude that a specimen is at work. There is, however, only a drawing. Mr. Bourdon, of

Paris, exhibits a governor upon exactly the same principle, worked by his own peculiar centrifugal pump. In the first case the semblance is noticed, while in the other the substance is passed over.

Subdivisions III. and IV. are distinguished by some rather peculiar phrases, enlivening the dreary list of machines, each allusion or attempt at description being grafted on to the others by a running commentary of "soft saw-"der." Such sentences as "to profit by this "property" (Subdivision III., Section III.) and "this pump has the general disposition of "a fine engine pump" (Subdivision V., Section I.) are, we dare say, excellent French. As English, they seem to us as being rather calculated to mislead anybody that has not cultivated the language of "the most polite nation in the "universe." "To profit by this pro-"perty," has a rather High Court of Chancery sound about it. "The general dispo-"sition of pumps," at least about London, is said to be a bad one. London pumps being somewhat "disposed" to weaken "lacteal "produce." We should like to know what is new in Messrs. Carrett, Marshall and Co.'s donkey pump, that those "constructors" are dignified by its long description.

In this part also it is mentioned that Appold and Gwynne's respective centrifugal pumps offer "no essential difference except in "the position of the axis of the wheel, which is "vertical in the first, and horizontal in the "second."

We, in our ignorance, always thought that there was an essential difference in the vanes. There also happen to be several small pumps of Mr. Appold's in the Exhibition with *horizontal* axes. In a description of F. O. Ward's hydraulic press pump, *four* pumps are distinctly given to the arrangement, when there are only two in the Exhibition. We have no doubt that a further investigation would show many more mistakes, but we have mentioned enough to show the way in which this report has been got up.

It looks as if some fatality, some malediction lasted in the executive of the Exhibition. Nothing that they do, or have done, directly or indirectly, seems to prosper. Unlike the fabled King of old, whose touch transmitted everything into precious metal, their hands turn everything into rottenness. Visitors and exhibitors, English and foreign, gurantors and employés, all alike, have successively turned away with disappointment. Any success that has been achieved, has been like the success of a soldier's victory, owing nothing to the generalship of the leaders. The history of the management is simply the history of a succession of blunders. The building is an abortion, badly lighted, ventilated, and arranged, setting at defiance all science and taste. Built according to an absurd contract, it is, from every point of view, scientifically, artistically, and commercially—a failure. The arrangement of the things exhibited, the official catalogues, the "Cadogan" commissariat, the distribution of the awards, the so-called reports, the different "positively the last times;" all these things have provoked smiles of derision from one end of Europe to the other.

IRON WALLS AND NAVAL GUNS.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

SIR,—I must not complain of being drawn into a controversy I have provoked. Having thrown down the gauntlet, I am bound to enter the lists and meet all comers who offer battle. Some of them are sturdy combatants, but I am prepared to encounter and repel their assaults like a knight "*Sans peur et sans reproche.*"

The first to break a lance with me is Mr. C. J. Richardson, a *preux chevalier*, who bears his device, "deflection," emblazoned on an enormous shield. He is bold and confident in attack; we shall see how he will fare. It is a pity to make so gallant and honest a partizan bite the dust, but I must strike home when fame and reputation are at stake.

I am "altogether wrong," Mr. Richardson boldly states, in calling the systems of Mr. Roberts and Mr. Westwood "angulated." If I were wrong, I should keep the word of which he reminds me, and admit my error—but I am not wrong. I have yet to learn that an angle is not an angle because it is *small*, for that is the sum and substance of my assailant's argument. In criticising my objection to "angular projections," he admits that I "justly remark they may be readily shot away," and in the same breath protests they are not angulated. It is hard to please everybody with names, but I must maintain "a spade is a spade." In my letter of the 24th October, I alluded slightly to Mr. Richardson's deflective shield, and I had no intention of exposing its defects, for I thought the questton was disposed of, and that even the inventor himself, whatever might be the merit of the plan in theory, was convinced it could not be realised in practice. But as he will have my opinion, I will give it. On the last day of the Exhibition, I took a good survey of the gigantic drawings of the "deflective shields" suspended on the walls of the Military Engineering Department. They would have been attractive in the picture gallery. After careful inspection, I discovered that, what with the apex of the main cone and the smaller cones or bosses, to protect weak points and bolt-heads, there are, within the area of one shield, 20 ft. in diameter, eight or nine of those protruding points which Mr. Richardson acknowledges I justly condemn. On a closer examinatiou I observed that the main support of the armour, the central bolt, is in the most critical position, inasmuch as its security depends upon the advanced angular projection, which covers it, remaining intact. Now, I hold that this culminating point would be shot clean away by the first heavy round or flat-headed shot which struck it. Thus a breach would be made in a vital part, and the next shot which hit within a foot of the fractured apex, would smash right through everything. The smaller lights would share the fate of the greater luminary—the little bosses would be more easily demolished than the big one.

In what I have said about deflection, after *quiet consideration*, I have not a word to retract. If it be a truth, it is only of value when developed by the smooth surface of a continuous curved or inclined plane. Now this is not the characteristic of Mr. Richardson's central and satellite protuberances, any more than it is of Mr. Roberts's or Mr. Westwood's projecting points. At whatever period of my first series of letters I first used the *word*, Mr. Richardson, if he searches, will find that I did in your journal frankly and fairly discuss the *subject* of deflection, on its real merits. I do not wish to shelve it. It is not in my nature to do so with any question. I will briefly reiterate a former statement. The Iron Plate Committee made a number of experiments at Shoeburyness, to test the principle of deflection on plates at angles, of, I believe, 45 deg. to 60 deg. to the horizon. These are deflecting planes far more favourable than that of Mr. Richardson's shield, which I take to be about 70 deg. or 20 deg. from the perpendicular. From the results of these experiments the committee came to the conclusion—a conclusion which was formally promulgated at a meeting of the Society of Civil Engineers—that taking the same vertical height perpendicular or inclined, the same weight of iron offered the same resistance. In other words, whatever is gained by deflection, in reducing the thickness of the plate, is lost in the increased length of the incline as compared with the perpendicular surface.

Mr. Richardson's illustration of a Highland shield is not happy. Its boss, its convex rim, and its broad expanse, were admirable to turn off the stroke of the broad sword and cover the person of the warrior; but that form of shield was a frail defence against the battle-axe or the ponderous mace, either of which, wielded by the strong arm of a powerful man at arms, fell like a projectile on one point and crushed through the weak places. He evidently has taken no account of the *angle* of deflection, which is the very soul of the principle. At an acute angle to the plane of the line of flight of a projectile, deflection is fully developed and penetration is frustrated. An angle of 45 deg. would seem to be the maximum inclination from a horizontal line for useful effect. If that theory be correct, a more obtuse angle of inclination would deflect so little that practically it would be no better than a perpendicular. Hence, apart from its defects of construction, the deflecting action of the Richardson shield on the side of a ship would be *nil*.

I think your readers, who are judge and jury in these friendly trials in your columns, if not the plaintiff himself, will admit my defence is good, and will find a verdict to the effect that, in all I have written about angulated projectiles and deflection, I have been, if not wiser than others, at least consistent; and in spite of Mr. Richardson's bantering, which I take in good part, I trust we part on friendly terms, for I have not time to carry this discussion any further.*

I must now do Mr. St. John Vincent the justice to say, that, having well-considered his deflective plan, of which diagrams appeared in the MECHANICS' MAGAZINE, it is, for the side of a ship, the most intelligent I know of. I did not at first embrace his conception of clothing the side of a vessel with one breadth of plate, extending from the required distance below the water-line to the gunwale. I have read his long letter, addressed to you, Sir, and examined his second plan, with much attention, but I do not think it would promote his interest, or be of any public use to give it publicity. The combinations of the plan are most ingenious, and exceedingly well-devised. They result in the formation of a girder of equal strength at all parts—precisely the principle I have constantly advocated — and covering each side of the ship, from stem to stern, with a coat of mail, which might be the hull of the ship itself. But these combinations resolve themselves into the *crucial* test, the *fastening*. The whole system depends upon screw-bolts, holding the outer plates, which Mr. Day calls the "joint pieces," into the backs of which the screw points are tapped. That gentleman probably is not aware that the experiments of the Iron-plate Committee seemed to justify the conclusion they arrived at, that this mode of fastening is inadmissible. At different target trials the points of screw-bolts tapped into plates snapped short off at the first thread, and, in one remarkable instance, every bolt was thus destroyed, and the plates fell bodily off the supporting iron frame. In some of my earlier let-

* We cannot afford any more space at present for this controversy on deflective armour.—ED. M. M.

ters these experiments are described, and the result is endeavoured to be accounted for by assuming that the screw-bolts, being incorporated with the plate, and at the same time holding it, they become the points of resistance, which receive the shock of impact, and hence are fractured by vibration.

Q in the corner—I beg the gentleman's pardon—"Q.X." thinks he has got me on the hip. But he has not. He is a technical and verbal critic, with whom one must mind his P's and Q's. So I will be as technical and verbal as he is. I will ask him to be kind enough to point out when and where I have stated that the power which propels a cannon ball, and the power which drives a punch, are identical in their nature. I never said so or thought anything of the kind. In establishing a parallel between gunpowder and a machine, I simply said they were respectively the driving power in each case. "Q.X." has pointed out a difference in the *action* of the two forces, which is a matter of fact, and I thank him for drawing my attention to that difference, because it strengthens the case I want to establish, believing it to be a great and important truth, namely, that a projectile fired against an armour-plate *"pari-passu" cannot do more work than a punch driven through a boiler plate.* I assumed that the action of the two forces was of the same nature. If, then, from the moment of impact, that is, of contact of the gun punch and the machine punch with the surface of the plate, the former is propelled by a *diminishing* force, and the latter by a *sustained* and *undiminished* force, it follows that the projectile will not do so much work as the boiler makers' punch. As Antonio said to Shylock, "I thank thee, "Q.X.," for that word." My friend —I hope he will allow me to call him so—is troubled because I say the resistance of wood against 100 or 150-pounders is of little or no use, and he kindly reminds me it offers *some* resistance. Again, I never said it did not; but I write and think for a practical purpose, and in expressing my ideas, I use the common conventional forms of language which all *educated* persons understand; and I really should think it a work of superrogation to be always reminding the scientific readers of the Mechanics' Magazine, that the density, weight, and resisting power of wood, as compared to those of iron, are only 1-9th or 1-10th. When a ship sails badly we say she makes *no* way; when a horse is a screw we say he has *no* go in him; and when a man is not over bright we say he has *no* brains, whilst every one understands that this form of negation simply means a comparatively infinitessimal small quantity. The Champion—to whom, in closing the lists for this bout, I have to give the *coup de grace*—as a triumphal clincher, asserts that wood not only does resist the shot, but would finally stop it altogether, "if there was enough of it." True, and so would tallow or butter, *if there was enough of it;* but surely that is not an argument in favour of one or the other, when circumstances render the use of *enough* of either as a backing to iron plates an impossibility and an absurdity.*

A plan of ship's armour, described in the *Engineer*, by J. H. Stacey, has been brought under my notice. It consists in placing narrow bars of iron either horizontally or vertically edgeways. I suppose Mr. Stacey does not read the Mechanics' Magazine, and therefore has not pored over the lucubrations of your humble servant. If he had done so he would have known that his idea is no novelty. It is carried out with the so-called Thorneycroft bars, but which really are the joint invention, under letters patent, of Mr. Lancaster, the well-known gun maker, and Mr. John Hughes, an engineer of practical experience in the manufacture and effective use of iron. These bars, 8 and 10 in. in width and 4 in. in thickness, placed horizontally, were applied to the construction of trial targets and experimented upon at Shoeburyness last year. The thickness in this case exceeds that proposed by Mr. Stacey, but the principle conceived and the objects are the same, namely, the resisting force of narrow bars, edgeways, and economy of price. The result of the trial, in respect of the resisting force of bar iron, was not unsatisfactory, but the mode of fastening and of tongueing and grooving the bars adopted by the inventors were fatal defects; and, as will be seen in the reports of the trials at the time, the targets were demolished. I agree with Mr. Stacey that the plan has merit, and deserves serious attention, but the fastening is the obstacle to be overcome, and it is not a small one. The plan shown in the drawing would, I think, not answer. The holes through the thin bars laterally would inevitably cause them to crack across the perforations, and the suggestion of bolt heads and nuts let into *adjoining* plates, or countersunk rivets, is so crude and vague, it is of little value, and cannot be relied upon, unless it be brought into a practical and workable shape. The thinner the bars the greater the difficulty of fastening them, because there is so small an area of metal to lay hold of. I do not, however, say a good fastening for bars may not be devised. I, long ago and often, have expressed a strong opinion in favour of bars or narrow plates for the armour of ships and forts, in preference to the ponderous and unwieldy masses of iron now in use. From these explanations Mr. Stacey will perceive his idea is not original.

CIVILIAN.

* Mr. Cheverton's letter on this question, which will be found in another column, was in type last week, and not inserted for want of space.—Ed. M. M.

ON THE WEAR AND TEAR OF AGRICULTURAL STEAM-ENGINES AND THRESHING MACHINES, WHETHER FIXED OR PORTABLE.*

By Henry Evershed.

In this paper an attempt is made to estimate the cost of repairs and other charges on agricultural steam-engines and threshing machinery. The costs in question vary largely, according to circumstances. We adhere strictly to actual returns and to cases that have come within our own knowledge, selecting specimens of various results—good, bad, or moderate—in the hope that the reader may be able to strike an average applicable to his own case, and to establish a reliable basis for calculations as to the cost of steam-power, whether used for threshing—which is more especially considered here—or for cultivation.

Repair of Portable Engines.

A 5-horse power portable steam-engine, belonging to the Right Hon. the Earl of Stradbroke, of Henham Hall, Suffolk, which was used to do the work of the home farm, including threshing and grinding corn, and cutting chaff for a large stud of horses, and for farm stock, cost for repairs as follows:—

		£	s.	d.	£	s.	d.
1852. April 17th.	Cost of 5-horse power engine, £180.						
1853. Sept. 29th.	Material	0	2	3			
Oct. 28th.	Fire-bars	1	13	4			
					1	15	7

"	Flue-brushes	0	6	0			
					26	15	11
1858. March.	Repairs and bars				10	15	0
	Total cost of repairs in six years				£57	3	11
	Average, £9 10s. 8d.						

* From the Journal of the Royal Agricultural Society.

But it must be further stated that in the following year the engine required a new fire-box and extensive repairs.

An 8-horse power portable steam-engine, belonging to Mr. E. Cottingham, Dunningworth Hall, Suffolk, gave this result:—

		£	s.	d.	£	s.	d.
1858. December.	Cost of 8-horse-power engine, £235						
1859. February.	Fire-bars	1	0	0

Nov. 26.	Repairs	8	11	6			
					16	14	11
	Total cost of repairs for three years				£24	15	7
	Average, £8 5s. 2d. a-year.						

This engine is used to thresh, cut chaff, and grind corn, on a farm of 1,500 acres, nearly all arable, and is used nearly three days in a week.

The following are the costs of repairs of an 8-horse power engine, bought October 20th, 1856, worked about three days a week, omitting fire-bars—which have averaged £1 15s. yearly for 8-horse power engines; and £1 8s. yearly for 7-horse power engines. This engine is under very excellent management, and belongs to Mr. Willsher, of Petches, near Weathersfield, Essex.

					£23	12	0

1860.
Midsummer. New fire-box and new tubes, smoke-box re-repaired, &c., £45.

The fire-box of this engine lasted a much less time than usual; the cost of repairs up to the time of its renewal was £5 18s. a year.

We have selected these detailed statements of the costs of repairs from a great many similar ones lying before us, and which we omit, as they would only crowd the pages of the Journal without giving any additional information. We have returns of the cost of repairs of at least 20 portable engines, varying in amount from £4 to £14 yearly for an 8-horse engine, exclusive of the cost of new fire-boxes. When so much depends, not only on the amount of work done, the quality of the water used, the care and intelligence of the engineer, but also on the inherent difference

existing between two engines turned out of the same workshop, it is not easy to make an average estimate of the cost of their repairs.

By far the most costly item in this account is the renewal of the fire-box, which, with carriage, will cost from £35 to £45; and there is no surer test of the treatment which the engine has received, than the early and repeated recurrence of this demand. I am informed by a friend that his engine—now in its fourth year of use—already requires a new fire-box, although it has worked but once a week, and been supplied with soft water. My friend, however, is not surprised at this, because he has left the engine entirely in the hands of a farm labourer.

An eminent maker informs me that with good management the fire-box of a portable engine, used two days a week, will last at least seven years. Several instances of its lasting ten or eleven years, when used twice a week, have come within my own knowledge.

To show how much this outlay may be diminished, if an engine be well attended to and protected from dust and damp, I give the following extract of a letter received from the owners of a 5-horse power portable steam-engine, used in an adjoining silk-mill, and kept constantly under the care of skilled mechanics:—"The engine was worked in the mills about 6½ years, and about two days in the week during the whole of that period. The repairs done to it were not extensive. The tubes at the fire-ends were once caulked round to stop leakages, and afterwards eight new tubes and two new collars were put in, the cost of the whole of which was about £8." This statement does not pretend to include every item of repairs; but after 6½ years there was no sign of injury to the fire-box of this engine, showing how much the outlay depends on good treatment and favourable circumstances.

Repairs of Fixed Engines.

The following were the repairs done to an overhead 10-horse-power fixed steam-engine, fitted with extra large boiler for burning wood, in 1853, belonging to the Right Hon. the Earl of Stradbroke; price, not including fixing, £350:—

		£	s.	d.	£	s.	d.
1854.							
Jan. 30.	Repairs	0	15	0			
July 15.	Adjusting engine-slides	0	13	6			
,,	Water-gauge glass & grummets	0	4	9			
August.	Excentric band repaired	0	10	6			
,,	Furnace-bars	1	4	0			
					3	7	9
1855.							
March.	Repairs	5	3	6			
Dec.	Bars and new back	2	17	0			
,,	Screws, &c.	0	5	6			
					9	6	0
1856.	Nothing.						
1857.							
March.	A cast back to furnace and bars	1	10	6			
April.	Piston taken out and repaired	3	15	0			
					5	5	6
1858.	Bars				1	10	9
1859.	Nothing.						
1860.	Same.						
1861.							
July.	Repairs to piston, &c.				4	7	0
	£2 19s. 7d. per annum for eight years				£23	17	0

This is the only *detailed* estimate we possess, and the gross sum happens to be heavier than in any other return. On the whole, we believe that £3 per annum for the first ten years will cover the cost of repairs of an 8 or 10-horse fixed engine, well managed, and used as often as it is likely to be required on any large farm. At the end of that period the cylinder will probably require re-boring, and a general repair of the engine and boiler will be needed, at a cost of about £40.

In order to estimate the proper charge for repairs and depreciation, we must know how long the engine will last. Supposing the process of repair to be repeated, it is difficult to assign a limit to the duration of a well-made engine, simple in all its parts as a non-condensing engine is now made. We shall, however, for purposes of calculation, suppose that at thirty years old an 8-horse engine is worth £50 with its fixing, and that besides the outlay of £3 a year for lesser repairs it has in its tenth and twentieth years received a thorough repair, as before referred to, at a total cost of £80. The annual charge will thus be raised on the average of thirty years to £5 13s.

It remains for us to put a value on such an engine when thirty years old, and practically such valuations are of rare occurrence. If we estimate that an outlay of £40 will again be required for a general repair, and put a value of £50 on the engine as it stands, we arrive at the total sum of £90, or less than half price for an engine nearly as good as new. We have known a 50-horse-power condensing engine working at fifty years old, and said to be "as good as new."

Interest and Depreciation.

We must now attempt to arrive at a specific charge for the depreciation of a portable engine, however open to correction, wherewith to debit the account for threshing.

As to the value of a portable engine, ten years old and out of repair, any one who has had such a one to sell must have found it a most unmarketable article. Let us suppose it to be worth £40. The original cost of an 8-horse power engine having been £230, the depreciation of capital so invested (reckoned at 5 per cent.) is £26 13s. per annum; namely, £2 per annum, the interest of the £40 which the engine will be worth at the end of the period, and £24 13s., the value of an annuity (calculated at 5 per cent.) which could be bought for ten years for the £190, the sum supposed to be sunk.*

But besides these charges, there are certain other contingent expenses to be taken into account, such as buildings and shafts, straps and covers, which we shall include in the account of the threshing machines.

An 8-horse portable engine requires a house 12 ft. wide by 20 ft. long, by 10 ft. high up to the plate; the roof should be of galvanized iron; total cost, including large folding-doors, eaves' trough, paving, and tank, £30, which at 7½ per cent. per annum comes to £2 5s.

The building for a fixed engine should be of a somewhat more substantial character, costing about £40, and to this we add the cost of building the chimney-shaft (40 to 45 ft. high, and made square for the sake of economy), setting the boiler, foundation for engine, &c., bringing the total cost to £120. This estimate applies to the Eastern Counties; in the North it would be lower, and in the South rather greater. The rent for this building at 7½ per cent would be £9.

Table showing the probable Cost of Repairs and Depreciation for portable Steam Engines.

Horse-power.	Price.	Suppos'd Value in 10 Years.	Amount of Depreciation and Interest per Annum for 10 Years.	Amount of Repairs per Annum for 10 Years.
	£	£	£ s. + £ s. = £ s.	£ s.
4	165	30	17 10 + 1 10 = 19 0	0
5	180	30	19 9 + 1 10 = 20 19	0
6	200	35	21 8 + 1 15 = 23 3	0
7	215	40	22 12 + 2 0 = 24 12	11 0
8	230	40	24 13 + 2 0 = 26 13	11 10
10	290	50	31 2 + 2 10 = 33 13	13 10

Charge for Engine-Shed, £2 5s.

Cost of Repairs and Depreciation for fixed Horizontal Engines.

Horse-power.	Price.	Suppos'd Value in 30 Years.	Amount of Depreciation and Interest per Annum for 30 Years.	Amount of Repairs per Annum for 30 Years,
	£	£	£ s. + £ s. = £ s.	£ s.
4	120	30	5 16 + 1 10 = 7 6	4 10
6	160	35	8 2 + 1 15 = 9 17	5 0
8	200	50	9 14 + 2 10 = 12 4	5 13
10	240	60	11 16 + 3 0 = 14 16	5 13
12	280	70	13 12 + 3 10 = 17 2	6 0

Rent of Buildings, £9.

Repairs and Depreciation of Portable Threshing Machines.

Mr. Willsher's 8-horse power finishing machine, bought in 1856, has cost:—

		£	s.	d.	£	s.	d.
1856.							
October.	Straps and thongs				0	8	6
1857.							
Nov. 27.	New brasses	0	13	6			
Dec.	Straps	0	6	10			
					1	0	4
1858.							
Nov.	Machine overhauled, new brasses, and straps				2	15	9
1859.							
August.	Machine overhauled, nearly all new brasses, new straps, and repairs				6	18	0
1860.							
April	Straps and brasses	3	1	0

					34	11	0
	£9 2s. 9d. a-year for five years				£45	13	7

His 7-horse single-blast machine has cost:—

		£	s.	d.
1854.	Straps, &c.	0	12	9
1855.	Brasses and straps, repairs	4	3	0
1856.	Shaker-brackets, straps, brasses, &c.	4	11	0
1857.	Machines overhauled and general repairs, renewal of brasses, &c.	10	11	0
1858.	New drum and concave, general repairs, painting, and wearing parts renewed	27	5	0
1859.	Straps, &c.	1	2	6
1860.	New brasses and straps, repairs by carpenter, &c.	6	17	0
1861.	Machine overhauled, new wearing parts, &c.	9	18	6
	£8 2s. 7d. per annum for eight years	£65	0	9

The average of our returns is from £8 to £13 a year for an 8-horse-power single-blast machine, working two days a week.

Besides the items given there is the cost of driving-straps and of waterproof covers for both engine and machine. The cost of all these depends entirely on the care taken and on the amount of exposure to wet. Either a cloth or a strap doubled up wet will soon be spoiled. We have known a good strap, costing £5, last three years with pretty constant work, but a neighbouring letter-out of machines estimates his expenses in driving-straps for one machine at £4 per year, and in waterproof covers at £2.

Finishing machines, constructed with a double, or often a treble blast, have such numerous bearings and driving-straps, and are so complicated, that the cost of their repairs has been in some cases enormous. Considering the extra power, or the slower feeding, which they require, and that corn can be finished by hand for 1d. per quarter, we doubt whether their employment is generally economical.

At all events they require to be simplified, and improvements such as those of Messrs. Garrett and Son, who obtain a blast of air by a fan fixed to the drum spindle, deserve notice and encouragement. Mr. J. C. Willsher has also, with the same object, lately patented an arrangement for driving the shakers and carvings-screen, either with or without a riddle-box and corn-screen, from one crank spindle and with one strap. Messrs. Clayton and Shuttleworth have also introduced a new elevator, consisting of spades or scoops fixed on the same spindle as the blower, which by revolving rapidly throws the corn up into the second dresser and awns the barley, or chobs the wheat, so as to dispense with the straps of the former elevator and barley-awner. Messrs. Ransome's adjustable rotary screen, though ingenious, can hardly be classed among those novelties which tend to simplify the machine.

A survey of the vast amount of ingenuity which has been directed by different makers to the working parts of the machine—the drum, beaters, shakers, riddles, and more recently to the elevators—creates the impression that no one maker can claim unrivalled superiority over the rest in every respect, but rather that a much better machine would result if the *good points* in each pattern could be combined together.

None but machines by the best makers should ever be selected, however tempting a bait may be held out in other quarters by a lower price. Competition has lowered the prices to a level which will not admit of further reduction without the substitution of inferior workmanship; and this, whether a steam-engine or so simple a machine as a turnip-cutter be in question. Inferior workmanship will always prove the dearest in the end. Among other reasons for buying fir t-

* In this calculation both interest and depreciation are included.—P. H. F.

class machinery may be mentioned the importance of having the wearing parts properly numbered, so that they can be fixed by a common smith. The best makers take care to provide these for their customers; others may expose you to disappointment and expense for want of this provision.

(To be concluded in our next.)

THE PREVENTION OF DECAY IN TIMBER.*

The large excess of the annual consumption of timber over its reproduction has led the author of the essay under notice to consider what remedies might judiciously be adopted for the prevention of its decay. Although Mons. de Lapparent treats of the subject more especially in its relation to timber for ship-building purposes, his observations and the suggestions founded upon them, are equally applicable to timber used for building and railway works. The principles are the same in all cases, whether applied to the ribs of a ship, the sleepers of a railway, or the beams of a house. If, by the judicious employment of known means, we doubt the durability of the timber, we allow the young trees a proportionate length of time to reach maturity, we double, at once, our natural wealth in the material, wherever it is used, as well as from the forests in which we gather our supplies. The longer we prolong this durability, the more valuable does the timber become through the absence of any need for renewal, and the more surely do we guard ourselves against a scarcity; the disastrous effects of which are already felt in many parts of France.

With that portion of the essay devoted to ship-building, and to a consideration of the relative advantages of iron and wooden ships, it is not our province to deal, but the insufficient seasoning of the timber, which renders many new ships in a few years almost worthless, is an evil largely introduced into modern houses. The channels or space between a ship's timbers, into which there is a constant supply of aqueous vapour from the unseasoned wood, have their counterparts in the floors of our houses. The elements of fermentation, and consequently of decomposition of the ligneous fibre, are produced from similar causes in both instances. The author says:—

"Timber, sound at the heart and exempt from all accidental and local defects, only decays under the influence of certain causes, which it is important carefully to define, in order that we may be enabled to combat them successfully.

"When a tree is felled it encloses in its fibres as well as in its capillary channels a considerable quantity of sap, which is nothing else but water charged with gummy, saccharine, saline, mucilaginous, and albuminous matters. In this state the latter are very liable to ferment, but they lose this liability when, by the evaporation of the sap, they pass to a dry and solid state; so that the first suggestion which naturally presents itself to the mind, is to subject the timber to a lengthened seasoning.

"Unfortunately timber in general, and particularly that of the oak species, requires a prodigious long time before the mass is thoroughly seasoned. This arises partly because (the wood being inaccessible to heat) the sap, excepting that immediately below the surface, does not exude in vapour —the only form in which it could escape quickly— and partly from the incrustation and the narrowness of the channels, which present a more or less powerful obstacle to the evaporation of these exhalations.

"A natural seasoning would be sufficient for specimens of moderate thickness, such as boards for inlaying and panelling, &c., &c., or even for some thicker woods, from which in working up they take off only a thin shaving from the surface—for example, the planking of ships; but it would be entirely useless as regards rough square logs intended to be used as ribs, and from which from 40 to 50 per cent. of the original mass is taken off. Then, however seasoned the exterior may appear, a considerable degree of dampness is found under the fibrous tissue of the wood. Exposure of the timber to free air for some length of time can alone remedy this evil."

But as our inability to wait a sufficiently long time for the natural seasoning of the timber has been the cause of our employment of an inferior quality, it is practically useless to insist upon, and rest content with, that means of attaining our object. We must resort to artificial and speedy methods for obtaining similar results. Mons. de Lapparent's methods consist:—

1st. In depriving the timber of the greatest possible quantity of sap, and consequently of the fermenting principles therein contained.

2nd. In subjecting felled timber, before putting together, to an artificial seasoning.

3rd. In charring or scorching the surface of the wood by means of a slight carbonisation when the work is finished.

These different methods are examined and elucidated in regular order. The well-known fact that wood dries more rapidly the longer it has previously remained under water, is explained with remarkable clearness. The water, constantly changing all round the submerged timber, concludes by taking the place of the sap which issues forth and carries with it the fermenting properties with which it is charged. Then as pure water evaporates much quicker than that which contains foreign matters, the previously submerged timber is sooner seasoned. The time required for timber to remain under water, in order to get rid of its sap, is estimated by the author at one year in river water, two years in fresh water frequently changed, three years in brackish water always changing. Boards thus prepared would, after being left subsequently to season themselves naturally in store for two years, be ready for working up, but "rough timber for ribs" needs an artificial seasoning.

The various plans for artificial seasoning are then explained, and with them their defects. The plan of injecting gradually-heated air into the drying-stove where the wood is placed, leaves the inferior fibres of the wood of their original bulk, whilst those near the surface have a tendency to shrink and cause cracks and splits of more or less depth. This results from wood being such a bad conductor of heat. The heat cannot reach all the fibres alike. M. Guibert's method obviates this defect by "filling the drying-stove with smoke produced by the distillation of certain combustible matters such as saw-dust, waste tan, smiths' coal, &c. The distillation of the combustibles causing a discharge of steam, prevents the cracks and splits in the outside fibres of the timber.

Another method is the injection of sulphate of copper into the timber.

The principal cause of fermentation—the forerunner of decay—is, it appears, the presence of an atmosphere of warm, damp, and stagnant air:—

"On one of these three conditions being removed, the durability of timber would be immediately prolonged. Thus it is that we cannot contemplate without a feeling of admiration the woodwork of the oldest mansions or churches. To quote from Rondelet: 'The woodwork of the church of St. Paul, outside the city walls, which was destroyed by fire in 1823, was erected as far back as the fifth century. Although the atmosphere surrounding the framework is often at once warm and damp, yet it is never stagnant.' It is also known that timber has been preserved indefinitely under water. It may lose a portion of its elasticity and power of resistance by the absence of some of its properties, but it does not decay.

"The joists of the houses built by our ancestors last almost for ever, because they are in contact with air which is continually changing. Now, on the contrary, we foolishly enclose them between a ceiling of plaster (always very damp to begin with) and a floor; they rapidly decay, and sometimes cause the most serious disasters, of which it is impossible to be forewarned."

The signs of decay in timber are fungi, and the fermentation generated by prolonged contact with warm, damp, and stagnant air, is as a soil where seeds sow and nourish themselves.

The remedies are, consequently, to disturb the stagnant air, to get rid of the confined air in contact with the timber, to so prepare the surface of timber as to prevent the engendering and growth of fungi, and to impregnate the air in contact with timber with a substance destructive to the sporules of the fungi:—

The first remedy explains itself. The second consists in carbonizing the surface of the timber:—

"In the first place, the surface is subjected to a considerable heat, the primary effect of which is to exhaust the sap of the epidermis, and to dry up the fermenting principles—here this is done by long exposure to the air; and in the second place, below the outside layer, completely carbonized, a scorched surface is found, that is to say, partly distilled and impregnated with the products of that distillation, which are creosoted and empyreumatic, the antiseptic properties of which are well known."

Numerous instances of the efficacy of this method are given, for details of which we must refer the reader to the essay itself, where he will also find particulars of the cheap and simple apparatus by which the author disposes of all danger in the use of his process. The operation of charring the timber is facilitated by previously smearing it with a little tar:—

"By so doing these other advantages are gained—

"1st.—The carbonization of the cracks, that almost always occur on the surface of rough timber, is facilitated.

"2ndly.—It prevents the timber being affected too suddenly by the heat of the gas, which causes it to split.

3dly.—It prevents the cracking and splintering off of little ignited particles.

"But beyond a mere facing of tar we must not go; a little thicker layer would impede, instead of furthering, the operation. Besides, we must stop as soon as the surface is freely carbonized, which certifies that none of the parts below have escaped the charring, which is, I repeat, the end we seek."

It is suggested—and the suggestion is well worth consideration—that this process should be applied in house building:—

"In house-building, the process should be applied to the beams and joists embedded in the walls, or surrounded with plaster; to the joists of stables, cowhouses, washhouses, &c.—which, although exposed to the free air, are constantly surrounded by a warm and moist atmosphere, an active cause of fermentation—to the wainscoting of ground floors; to the flooring beneath the parquet work, to the joints of tongues and rabbets, &c.; for carbonization by means of gas still leaves to the wood, for working purposes, all the sharpness of its edges.

"By carbonization a practical and economical means is offered to railway companies of preserving, almost for ever, the sleepers, particularly oak, which cannot be impregnated by the injection of sulphate of copper. Let us suppose, for instance, that after, say 10 or 15 years, the sleepers on a line are taken up for the length of a mile, and replaced by new ones, the old, when rasped and burnt again, will serve for the replacing of the following mile, and so on, one mile after the other."

The charred timber, after being scraped and pumiced, may be painted in the usual way, and with any colour.

The impregnation of the air in contact with timber is managed by smearing, here and there on the surface, a species of paint, with flour of sulphur as a basis, and linseed oil as an amalgamator. This paint developes a slightly

* "An Essay on the Prevention of Decay in Timber for Ship Building and other Purposes," by Mons. de Lapparent, Officer of the Legion of Honour, Director of the French Dockyards, and Inspector of Timber for Naval Purposes. London: M'Kewan and Co., 46, London-wall.

sulphurous atmosphere, which purifies the air, by destroying, at least in part, the sporules of the fungi.

Such is an outline of the means pointed out by Mons. de Lapparent. They are, as he says, simple, logical, economical, easy of adoption, and perfectly innocuous. The arrangement for working Mons. de Lapparent's patent in Great Britain, has been intrusted to Messrs. York and Co., 32, Royal Exchange-buildings, where the system may be seen in operation.—*Building News.*

DISC GUNS AND PROJECTILES.

The following paper was read in Sect. G, at the meeting of the British Association on the 3rd October, by R. W. Woollcombe, Esq., of St. Jean d'Acre-terrace, Stoke, Devonport:—

Oblate Projectiles with Cycloidal Rotation, contrasted with Cylindro-ogival Projectiles, having Helical or Rifle Rotation.

Although a paper entitled "An Account of some Experiments with Excentric Oblate Bodies and Discs as Projectiles" was produced by me in March last, before the Royal Society, and was printed in their proceedings for May, yet the results of some further experiments with a model at Shoeburyness, as to penetration and velocity, appear to me of sufficient interest in a practical point of view to be brought to the notice of the British Association.

It appears that in gunnery the requirement of the day is some arrangement by which, in one shape or other, heavy solid shot can be projected with high initial velocity, yet such velocity be maintained better than it can be in spheres.

While ships were of wood there was a requirement for powerful and capacious shells, and such projectiles were forthcoming by the rifle principle, but (abiding the results of the progressing trials with Mr. Whitworth's punch-headed shells), the iron plates may be said to have brought solid shot into the foreground. Rifled cannon, it appears, cannot project heavy elongated shot with high velocity, and it is seen (again excepting Mr. Whitworth's results with flat-headed projectiles), that for the penetration of iron plates a high velocity is essential—at least within the more manageable weights—say up to 120 lbs. It seems that for heavy shot we have of late reverted to spheres, and thus, after an acquaintanceship not of many years' duration, have so far taken our leave of science for the solid projectile, retaining her aid only far the building up of Cyclopœan smooth-bore cylinders. A return to the smooth-bore cylinder would not necessarily be a retrogression; it might be an advance in science could we successfully project from the smooth-bore shot that are elongated; it is in the abandonment of elongation for the projectile that science has retrogressed. If, then (with the exception still under trial), we find that from neither rifled nor smooth-bored cylinders we can advantageously project, in respect of iron plates, heavy elongated shot, are we compelled by the requirements of the hour, therefore, to forego for the larger calibres the many advantages we have learned from the smaller calibres to appreciate in elongation? The question presents itself: "What is there in the rifle principle and in elongation by the cylindro-ogival form that appears to bar development,—that prevents a natural expansion from small to great calibres,—that in * practice makes the 80-pounder give scarcely more range than the 3-pounder, and but just now, when called upon for great action, has made this principle give place to the primitive sphere and smooth-bored cylinder?"—the reason may, I believe, be found in the artificial basis of the rifle principle. However well-suited the helical or rifle method with cylindrical elongation for the projectile may be for small arms, and for, perhaps, the lesser calibres in cannon, yet when we desire to so far imitate nature as to project with great and sustained velocities great weights, we might succeed better were our mechanical arrangements less antagonistic than are those of the rifle principle to certain great laws of nature, to the laws which have ruled in the form, method of rotation, and translation of what I may here term the great natural projectiles—the planets. Do we find any one of these to be a prolate body, projected with helical rotation about its longest diameter, and in the direction of such axis? In the two first conditions, namely, the prolate form and helical rotation, we have, I think, the clue to the small initial velocity afforded by, and inexpansive nature of, the rifle principle; and in the third condition, or the axis of rotation lying in the plane of projection, is the reason why the rifle principle has not done, and never can do, anything to improve vertical fire, or to be in any calibre effective dynamically except at very low elevations, a matter of no consequence in small arms. These defects are inherent to the rifle principle. Is there any other arrangement practicable in which, by a construction less in violation of the natural laws alluded to, the defects spoken of in respect of rifled cannon may not exist? In reply, I have to say that I have found it to be practicable to project a body that is, instead of being prolate, more or less oblate; that instead of having helical rotation at *the expense* of translation, has cycloidal rotation *in aid* of translation; a projectile that rotates about its shortest diameter, or the natural axis of rotation of a body naturally formed for rotation, instead of about the longest diameter of unnatural axis of a body not formed for rotation; that while the projectile has a circular periphery in line of motion in the gun, and can thus leave the bore as freely as a common round shot, yet has the additional security for high initial velocity of windage much† smaller than could be allowed for round shot of similar weight. That is, like the round shot, driving through the gun along a straight smooth bore, but as a wheel, instead of being forced into and through a helix as a screw, and thus conditions for a vast superiority in initial velocity given to it over the rifle projectile, and from the diminished windage much superiority in initial velocity over the sphere. The terminal velocity being also provided for by the oblateness, and for any elevation ‡ by the axis of rotation being transverse to, and not in the plane of the trajectory.

The gun being of similar transverse section to that of the projectile, the bore, as has been said, straight and smooth, the longer axis of the bore in a direction perpendicular to the common axis of the trunnions. The gun to be fired with the trunnions as horizontal as possible, as indeed all guns are. The projectile a disc, scarcely more costly in manufacture than a common round shot, and which is fit for use almost in the state in which it is taken from the mould. It must be slightly eccentric or it will not rotate. I find that not more than 1-50th of the concentric weight need be added or subtracted to secure rotation (less than 1-100th has given rotation in a disc). All *spherical* shells used by the American Federal States are purposely made eccentric by about a similar amount. All spherical shells are *inevitably* eccentric, so are ninety-nine out of a hundred spherical shot. I merely propose to apply to an advantageous purpose an eccentricity scarcely greater than is *inevitable* in any spherical projectile, and by such means to secure and multiply the advantages of virtual elongation by the cycloidal rotation of an oblate body instead of the helical rotation of a projectile elongated cylindrically, by which is to be, I believe, secured an initial velocity greater than that of a sphere *in a ratio increasing with dimensions*, and the conditions are afforded for maintaining such velocity at *any* elevation better than can be secured by the use of the rifle principle. I will mention briefly the results of some experiments shown to the Ordnance Select Committee in March last, with a small rough model. The gun was only $20\frac{1}{4}$ inches long in the bore, or $10\frac{3}{4}$ calibres in length. The calibre (long diameter), being about $1\frac{7}{8}$ inch, and the transverse or short diameter about $\frac{3}{4}$ inch. The shot weighed between $7\frac{3}{4}$ and 8 ounces. The experimental gun being externally a mere cylindrical block, weighed more than would have been otherwise necessary, and from also been of necessity built up and not bored, its weight was about 130 lbs. With a charge of $2\frac{1}{4}$ oz. or about 3-5ths the shots' weight, the penetration of 25 yards from an oak target was a mean of 11 inches reckoning to near side of disc, and to the far side nearly 13 inches. The initial velocity which gave this penetration was, as measured by Havez, Electro Ballistic Apparatus, 1,487 feet per second. Desirous of comparing a spherical shot with mine, the Ordnance Select Committee fired a few shots with a small brass gun, the length of bore of which was 34·625 inches, and nearly double the length of mine in calibre. The mean calibre of the committee's gun was 1·60 inch, but at the muzzle something more. The mean diameter of their shot was 1·48 inch. Fired with proportionate charges, the penetration of the disc gun was more than double that of the committee's gun in the oak, and its initial velocity as 1,487 to that of the committee's, 1,091.

The mean penetration of the committee's gun being 5 inches, that of mine 11 inches.

In these trials at the oak, all the discs fired with centre of gravity "above" in the bôre struck upright as fired.

At a subsequent trial for velocity some discs were fired which were laterally as well as longitudinally eccentric, and though they evinced by the holes in the target confirmed rotation on the desired axis, yet this rotation was not in one plane. At close quarters this would be immaterial, as the penetration is not effected, and I believe it to be very practicable to make discs sufficiently symmetrical and homogeneous laterally.

Excepting when the trajectory was square or perpendicular to the plane of the target, a condition that must be, I presume, very rare in actual service, a disc would have almost the advantage that a flat-headed cylindrical projectile has in respect of contact over one with a hemispherical or ogival head, while for the reasons I have already named the disc is likely to have a much greater velocity than any rifle projectile, in which case more effect is probable against iron-plates.

I will conclude by mentioning that even with this short model of 20 inches long, or $10\frac{3}{4}$ calibres, the velocity has approximated to that from the 68-pounder of 95 cwt., viz:—1494·4 feet per second as compared with 1553·3 feet per second, the former at 60 feet from muzzle, the latter at 90 feet, the former with $\frac{1}{3}$ of discs weight, or 2·625 ounces, the latter with 16 lbs charge, or about $\frac{1}{4}$ shot-weight.

I think, then, that having in view the great requirement of the day, in respect of projectiles, viz., the conditions for effecting the penetration of iron plates, it may, considering the above results, already appear worthy of regret that the subject has been permitted by the military authorities to fail to the ground without any further trial.

---

* Vide *Times* of Feb. 20th, 1860, for report of the Southport experiments:—Whitworth's 3-pounder at 5 degree elevation, gave 2,500 yards; 80-pounder at 5 degree elevation, gave 2,544 yards; each with a charge of about one-seventh the weight of projectile.

† For a round shot must be allowed a larger margin (windage) for defects in sphericity, than need a disc. The latter need only slide freely laterally, and can roll but on one axis. The round shot must have windage enough to roll on an infinite number of axes.

‡ As to the requirement of the tangent to the path does not obtain in the discs.

Forty cast iron guns, strengthened on Capt. Blakely's principle of wrought iron hoops shrunk on over the breech, and rifled according to Commander Scott's system, by order of his Highness the Viceroy of Egypt, were recently thoroughly tested at the Arsenal Butt, Woolwich, and, having passed proof, they were sighted in the Royal Gun Factories, and completed. They have been despatched to Alexandria for the service of the Egyptian Artillery. An additional number of guns on the same principle were fired at the Royal Arsenal Butt, with a heavy charge of powder and shot, having been purchased by the Pasha on the usual conditions, and will be completed in a similar manner.

ON MOULDING IN METALS BY MACHINERY.

We all are aware that in these days the machinery used in many branches of industry is getting consolidated in form and extended in application, and that we are continually exporting absolutely the same machines north, south, east, and west. There need be no apology, therefore, for enlarging upon the means used for manufacturing quickly and well the major part of the details of all machines.

Cast malleable iron and cast steel are also every year getting into extended use, and the foundry seems destined to play a more and more important part in well-conducted engineering establishments.

The alliance of chemistry and mechanics will no doubt be fruitful in further combinations, giving us more extended powers in practical metallurgy; causing us to rely more on what may be termed the "plastic" powers of the cupola, and less on the brute force of the hammer, for the development of mechanical conception.

In our volumes for 1856 and 1857, and since, we noticed several moulding apparatus, then new, but which have since fully justified the expectations we formed at the time respecting them; we now purpose to compare more fully several of the most successful ones that have come under our observation.

Success makes machinery as well as statesmen and generals; and to attempt to criticise all the schemes that have passed the "ordeal" of the Lord Chancellor's seal, might perhaps be interesting in certain respects, but would certainly tire the greater part of our readers.

It may be at once mentioned that, as yet, all these processes are more particularly applicable to a repetition of work. It will not pay to have a sewing machine to sew only one shirt. Those large workshops, therefore, that are so fortunate as to have this repetition, the sure road to wealth for a manufacturing engineer, have, most of them, one or the other of these more or less economical contrivances. As might be expected, we find them largely applied in machine shops for the manufacture of cotton, flax, and woollen machinery, and also agricultural implements. In what may be termed the "brickmaking" of the trade, the manufacture, namely, of railway chairs, pavements, shot and shell, where the great call is for rapidity of production, the use of a good moulding machine is of imperative importance. The application of machinery to these purposes brings, of course, the usual advantages in its train, not merely increased rapidity of production, but also the substitution of cheap labour for that of skilled artisans, superior finish and accuracy of the castings, diminished cost of trimmings, and considerable reduction in the cost of fitting up the details. Some of these machines have even additional special advantages, to be mentioned further on.

In 1850 and 1851 Sir Peter Fairbairn, of Leeds, and Mr. John Hetherington, of Manchester, together took out a patent, in each respective year, for their process, now well known under the name of "plate-moulding." According to this plan, still in extensive employment, the pattern to be used is first bisected or divided into two parts through the broadest face of the pattern, these two parts being severally attached to the opposite sides of an intermediate plate, being fixed on this plate accurately coincident, or opposite each other. This plate and the halves of the pattern thereon are then placed between two upper and lower mould boxes. The parts being correctly adjusted, the process of ramming sand into one of the boxes will produce half the mould. The whole, boxes, patterns, and plate, is then turned over, and the same process is repeated with the second box. The plate, with its pattern, and the box which happens to be uppermost is now lifted off and turned over, the bottom box being thus left clear. The mould in the two boxes, on being put together, will thus be ready to receive the molten metal. In patterns with any "undercut" or overhanging projections, these parts are fitted loosely to the pattern-plate, and left behind on lifting off the plate, to be afterwards withdrawn. Any cores required are of course placed in the usual manner. This process has, as we mentioned before, been in extensive use for the last ten years, particularly in Manchester, Leeds, and the surrounding districts. We are assured that it, in certain cases, turns out work at one quarter the usual cost.

Messrs. Howard, of Bedford, in 1856, brought out and patented some different arrangements for these purposes, half of the pattern being withdrawn from below by means of mechanism. The moulding plate is cut out to the shape of the pattern, like a stencilling plate, and it rests on a table, as shown in the above cuts.

The moulding-box being placed upon this plate, the pattern is worked up so as to protrude to the required extent through the opening. The sand is then thrown in, and rammed up in the usual way. This being done, the operative lowers the plate by means of a hand-wheel, working a screw or a rack. An exact impression is thus left by the pattern in the sand. The mould is then free to be lifted off in the box, and turned over, ready for the other half. The process is repeated or not, on the same table, fo this other half, according to the shape of the pattern. Similar plans to this had been used by Government, for moulding shot and shell, several years before this patent was taken out. Mr. Howard more particularly specifies arrangements for supporting those portions of the plate for sustaining the sand used in the interstitial vacuities of any pattern. For instance, the isolated opening within the rim and arms of any pulley.

A great number of these machines are said to be in use by the patentee at the Britannia Iron Works, Bedford, chiefly for plough frames and wheels. These works are the most extensive ones in the kingdom for ploughs—taking the same position in that trade as Clayton and Shuttleworth, of Lincoln, in engines and thrashers. There are several machines somewhat upon this general plan in the Exhibition.

One of these, No. 1,723 in the Catalogue, is exhibited by Mr. Stone, of Deptford. It is for moulding the brass nails for ships, &c. The machine forms the moulds for about 500 at a time. It consists of a brass moulding plate with as many prominences as nails intended to be cast, shaped like the heads of the nails. Each of these has a hole in it, and on pressing a lever, a point is brought up through each hole; each point with its small fixed disk at the bottom forming the entire shape of the nail. To take a mould from these, a box is applied to the plate, and the same rammed down. The points are then withdrawn, and the box removed and turned over. The channels for running in the metal are formed by counterpart projections between each separate nail-head.

Two moulding machines for the 40-pounder Armstrong shells are shown at Messrs. Greenwood and Batley's stand in the Western annexe of the Exhibition. Another machine for moulding the peculiar small segments used in Armstrong's shell; and two other machines for moulding the 32-pounders diaphragm shell are shown in Class 11, Military Engineering. We believe that all these were fitted up at the Royal Laboratory Department. They consist essentially of a frame, on the top of which is a cast-iron table, with a tray at the side as a receptacle for the sand. At each end there is a circular moulding plate cast on the table. Underneath each plate is a vertical slide, actuated by a rack pinion and lever. The top part of this slide is shaped into a cast-iron mould, a counterpart of the shell or shot, elongated or spherical, as the case may be. This mould protrudes upwards through a hole in the plate on the table, fitting exactly into it. The plate is accurately turned up to receive a circul r moulding box. The joint part of this box

corresponds to the turned part of the table, and is held firmly down on each side by means of two swivelling cramps. The box being in this position, the pattern is worked up to its proper height. The sand is then thrown in and rammed down. The pattern is drawn back through the hole in the table, the cramps swivelled on one side, and the box turned over.

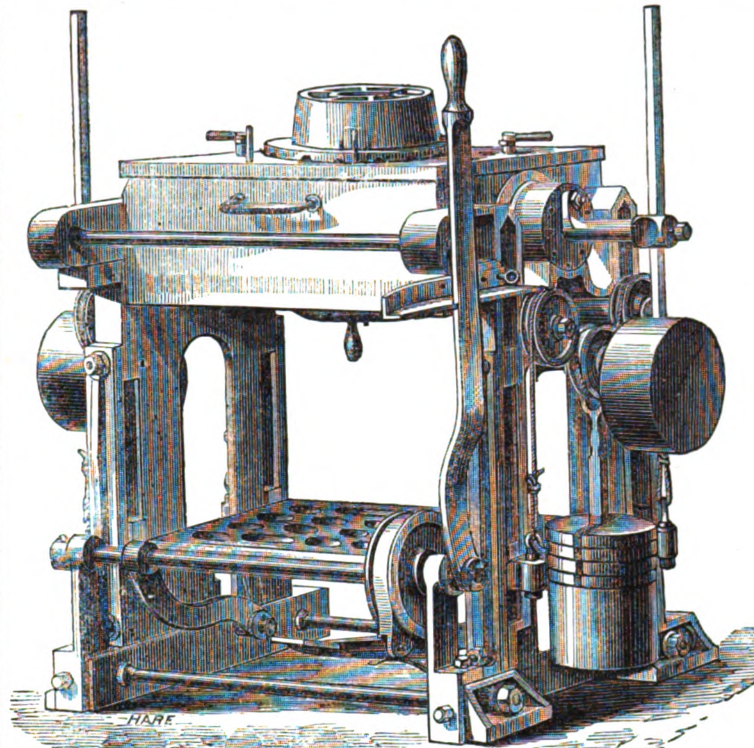
The bottom part of the shell is done in the same manner at the opposite end of the table, at the same time. The two parts are now ready for the core, and the two boxes being fixed together, the shell is ready to be cast.

The core is made in a somewhat different way on a separate machine.

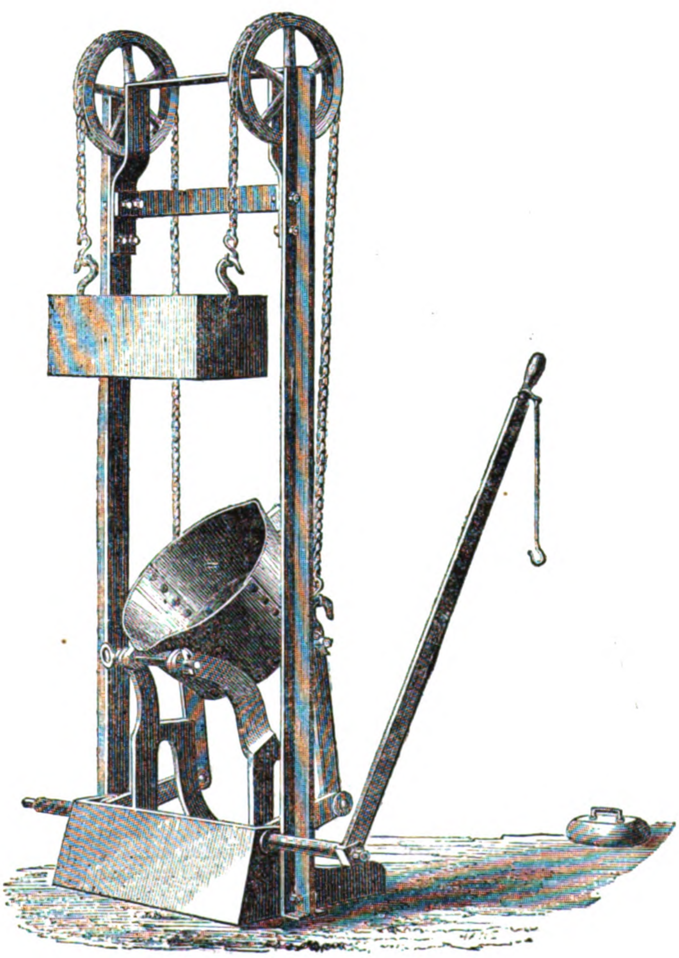
Two slides moved horizontally by a right and left-hand screw are each fitted to one half of a mould, which halves, screwed together, form the complete core. The gas-pipe core barrel is first placed in position and the sand is then thrown in and rammed down. The mould halves are then opened by turning the screws, and the core is then ready to be taken out and dried. The machine for moulding the segments of the Armstrong shells is exactly similar in principle to those above-mentioned ones for casting the bodies of shells. A number of models of the segments are raised and lowered through the moulding plate on the table. We believe that these machines are modifications of those introduced into the Royal Arsensal in consequence of the Crimean War. At that time considerable difficulty was experienced in procuring these projectiles, not only in sufficient quantity, but of sufficient accuracy to meet the requirements of the service. This, together with the high prices demanded by contractors, determined the War Office to ask a few leading mechanical houses to compete for a good moulding machine for shot and shell, and the one arranged by Mr. Greenwood was selected and adopted. Since that time a number of these machines have been in use, and have produced those piles of shot and shell which cover so large a space within the arsenal.

It is evident, on reflection, that in the machines we have just now noticed there must be a great objection at present, from the fact of the sand being *above* the pattern and *over* the opening in the plate when the pattern is being removed. It is thus very liable to fall back by its own weight and by the friction of the receding pattern. The results of this are of course an immediate injury, or even complete destruction of the mould, and similar effects, in course of time, on the whole machine.

The worst part of the labour of the moulder, on the usual plan, is the strain and fatigue



MOULDING MACHINE.



CASTING APPARATUS.

involved in lifting up and turning over the moulding box. We will now give a slight account of some moulding machinery that appears to us to meet these objections, at the same time offering advantages peculiar to itself. The figure shows a view, in perspective, of this machine, first brought out by Mr. Robert Jobson, of Dudley.

The moulding table or bed consists of a rectangular cast-iron box, open at top and bottom, and furnished with a large cylindrical axis at each end, about 6 in. diameter, turning in bearings on the side frames. The axes are prolonged at the ends, and counterbalance weights are attached to them by arms, which can be readily adjusted by lengthening or shortening, so as to balance the table with the mould upon it, leaving it free to turn upon the axes. The table turns half round, being prevented from turning further by stops upon the end of the moulding table, which catch in notches in the top of the frame. On the top of the table a plate is fixed by screw bolts, carrying the moulding box, which is secured upon it by two inclined catches with handles; this plate forming the ramming board upon which the pattern is fixed; and the moulding sand is rammed upon it in the ordinary way.

The machine is shewn as arranged for moulding *iron pavements*. Any other pattern can, however be readily employed, the only preparation requisite being to fix each pattern upon a bottom plate, having bolt-holes to correspond with those on the top of the moulding table. This arrangement is so simple, that after the machine has been moulding pavements, it can be changed and got to work again at moulding railway chairs or other articles within ten minutes time. As soon as the sand is rammed, the cover-plate is put on the box by sliding it on the inclined snugs which hold it flat; the whole is then turned over with the moulding table into the reversed position, this being effected by the simple pressure of pushing home the cover plate, since the whole is balanced and turns freely upon the axes. In moulding pavements, the pattern is then withdrawn from the mould sufficiently to make it clear the sand by means of the screw and hand wheel. A rising platform, which slides in vertical grooves in the side frames, is then brought up by means of the lever to touch the cover plate of the box which is now at the underside, and the box is liberated from the moulding plate by releasing the two catches simultaneously by means of the second handles fixed on the other ends of the spindles for the purpose. The platform now descends by means of the additional weight upon it to the bottom, the platform being counterpoised by the balance weights.

The mould is then removed by sliding it off the platform on to a little railway placed at the same level; and the machine is made ready for repeating the operation by screwing down the pattern to its right place, and turning back the moulding table to its former position, ready to receive a second empty box.

The principle carried out in this machine, of turning over the whole moulding table with the mould and pattern upon it undisturbed, has the effect of saving almost all labour in lifting the moulds; so that boys, who are sufficient for all the actual moulding work, are able to complete the process, instead of men being required to lift the heavy weights. An advantage in average quality of work and saving of wasters is obtained by avoiding all handling and risk of disturbing the moulds in lifting them off; they simply slide along a little smooth railway from the moulding machine to the casting ladle, which is fixed within 7 ft. 6 in. distance from the moulding machine centre to centre. An important point is also gained, as we mentioned before, by always replacing the pattern in its first position while still inverted, thus preventing any particles of sand from interfering with the working parts of the pattern. It is an essential point in machinery applied to such purposes as the present, that it should be arranged so as to keep in order for continued regular work, without requiring any nicety in management that would interfere at all with the roughness of manipulation inseparable from work, where economy of manufacture combined with accuracy in the castings are the objects to be accomplished. The result of the working of the moulding machine is such, that one mould, consisting of two railway chairs, is completed every minute on one machine; and the machine is found to keep so well in working order that the regular day's work of ten hours produces from 1,000 to 1,100 chairs, being at the average rate throughout of two chairs per minute. This rapidity of moulding by the machine could not be made fully available with the ordinary means of casting, on account of the large floor space required for casting with the necessary rapidity, and the consequent delay and expense attending the removal of the moulds over that space; and a great objection experienced at first in regard to economy of work was the large number of moulding boxes to keep even one machine going at the full rate. To meet these difficulties a casting apparatus was designed by Mr. Jobson, which is fixed close to the moulding machine; this is capable of filling the moulds as fast as they leave the machine, and within two or three minutes the operation of moulding and casting is completed in each case, and the box laid out in the open air to cool, ready for emptying and using again on the machine within about six minutes time.

This casting apparatus is shown in perspective in the annexed figure.

The ladle is placed in a standard frame upon the floor, the sides of which partly embrace the front of the ladle, as shown, and they carry a spindle at their extremities, which passes through two corresponding lugs fixed on the front of the ladle just below the lip. This spindle forms an axis upon which the ladle turns when pouring, and the ladle is lifted by means of a shaft fixed across the centre of the bottom and connected by links to the two levers, which are fixed on the cross shaft and moved by the hand levers shown. The weight of the loaded ladle is counterpoised by balance weights attached by chains hooked on to each end of the shaft and carried over pulleys upon the roof timbers or frame of the ladle. From the position of the axis on which the ladle turns, the lip of the ladle follows the direction of the stream of metal all the time that the ladle is being turned to its extreme position shown by the dotted lines, so that the position of the stream of metal is stationary in all positions of the ladle; the several moulds are therefore only required to be brought to the same spot in succession, and the metal can be poured in at once without any delay for adjustment of position, the moulds being filled as fast as they can be brought up to the ladle from the moulding machine. The command over the movement of the ladle given by the long lever makes the pouring of the metal very steady; and the whole being nearly balanced, the caster tilts the ladle with one hand whilst he skims the metal for himself with the other. A supply of fresh metal is brought from the cupola at regular intervals by a couple of labourers with an ordinary double-handed ladle.

In casting railway chairs by hand labour, it is considered a good day's work to obtain 300 castings from one man and his boys; and with the best plan the average does not exceed 480 per day. To produce this quantity the man who rams up the bottom box has to lift the following weights:—

Bottom box	26 lbs.
Patterns	45 lbs.
Sand	48 lbs.
Ramming board	12 lbs.
Total	131 lbs.

This total weight of 131 lbs. has to be divided by 2, as the box rests upon its edge while being turned over; therefore 131 lbs. divided by 2 = 65 lbs. After turning it over the man has to

Lift off the ramming board	12 lbs.
Draw the patterns	45 lbs.
Carry the box full of sand to the casting stage	74 lbs.
Add 65 lbs. brought forward	65 lbs.
Total	196 lbs.

which, multiplied by 240, the number of boxes moulded to produce 480 chairs, 2 chairs in each box, gives 47,040 lbs. or more than 20 tons to be lifted by the man during his day's work.

By using the turn-over table, a man has been regularly making from 1,000 to 1,100 chairs per day, in producing which he had to lift only the empty bottom box and cover plate.

Bottom box	26 lbs.
Cover plate	9 lbs.
Total	35 lbs.

which, multiplied by 550, the average number of boxes moulded, 2 chairs in each box, gives 19,250 lbs. or only 9 tons to be lifted in making the larger quantity, against 20 tons in making the smaller quantity by the old plan, the latter requiring accordingly about 5½ times as much labour in lifting per chair produced as is necessary with the machine.

With regard to the casting: by the ordinary plan of carrying the iron and pouring it into the moulds, for casting railway chairs, six men and three boys were required to each table, and a long length of rails, together with a much greater number of boxes; but by the new ladle one man is enabled to cast all that can be moulded on one table, and two metal carriers are sufficient for two tables; so that two men can in this department do the work of nine men and boys, and with less labour, since they have not to stand in a constrained position with a heavy weight, as they were compelled to do in filling the moulds by the ordinary hand ladles. Also the quality of the heat of the iron is greater from its being constantly supplied; and its purity is increased by being stirred up every time the hot metal is poured into the ladle.

We believe that this machine is getting into extensive use, not merely in England, but also in foreign countries. Amongst other firms in England, Messrs. Ransome and Sims, of Ipswich, had, we believe, 20 of these machines with a turn-over table in 1860. We believe that the number has since been increased. That firm state that they use this invention for "railway chairs and iron pavements, also for tooth wheels and machine castings, spring shoes, and railway castings generally."

Messrs. Platt Brothers, of Oldham, we believe, also use it very extensively for the innumerable small castings required in the spinning and weaving machinery they send to all quarters of the globe. An extraordinary saving in fitting up these machines is said to be effected from the fact of of there being no taper required in the patterns. The working of gearing cast in this way must be much sweeter from the parallelism of the teeth. When gearing is trimmed up to effect this, the casting is necessarily weakened in the process by the loss of the outside skin. As is well known, the presence of this skin, from its harder substance, also materially lengthens the duration of the teeth. As is usually the case with a useful thing of this kind, it has been combined with other inventions, and several improvements have been grafted on it. For instance, in order to form cheaply and accurately the moulding plate used in toothed wheels, the opening in the plate is made somewhat larger than is required for the passage of the pattern; and afterwards, when the latter is in its place, a fusible metal is poured into the space between the pattern and plate. There will thus be a perfectly correct fit between the two, this accuracy being acquired at very little expense.

We have also seen the turn-over table applied to what is called "block moulding"—a process well-known to most iron founders, having been in use for some years. This plan is particularly applicable when a number of articles of a very irregular shape are required. The irregular shape of the pattern requires, of course, great skill in the operative and much time, even when the greatest skill be employed. The pattern is taken, and two of the so-called "blocks," the respective counterparts of the top and bottom of the pattern, in all their intricacies, are formed from it by a peculiar but simple process. These "blocks," being principally formed of Roman cement, last for a long time, and, in a repetition of articles, the highest skill of a journeyman is thus transmitted to any boy.

In the operation of moulding, the boxes are simply placed on each of these ramming blocks, the sand rammed in, and the two sand moulds thus made are placed together. To form the complete mould for receiving the melted iron, suitable passages for the purpose are left in the sand.

Amongst several other additions that we might mention, Mr. Barrett, of Stockton, has applied a large turn-table as a means of communication between the different machines, the casting ladle and the railway for carrying off the completed castings.

It is our belief that these machines will take a place amongst regular workshop tools, as we have no doubt that the same machine can be employed for a variety of work during the same day. If we are not too sanguine, we might even predict that these machines may cause similar changes in the foundry to those effected by the slide rest in the fitting shop. Similar to the slide rest, the turnover principle diminishes both the skill and the labour required.

This principle, applied to moulding machines, seems to us one of those arrangements general in their nature, and dependent upon a simple mechanical contrivance for their realization, that give real value and strength to a patent. To make our meaning clearer, we might, perhaps, instance Mr. Fowler's plan for making his ploughing anchor self-acting by means of the traction rope.

Any mechanic, with the right to use the traction-rope in this way, might no doubt work the anchor forwards on a variety of plans. Mr. Fowler, being the proprietor of the patent, embodying this principle, is thus, however, ahead of any other inventor. In these times of "patented invalids" this is no slight consideration.

II.

Col. Henry James announces that they have, at the Ordnance Survey Office, Southampton, accidentally made the important discovery that the paper prepared with the bi-chromate of potash and gum only, as described in the work on Photozincography lately published by Messrs. Longman and Co., will, if only kept for a week or ten days in the dark, yield half tones, and consequently give us lithographic or zincographic prints from any photograph.

Mr. W. Riddle writes to ask how it is that the Mersey Company's breech-loader, which fires 19 times a minute, is ignored.

ECONOMISING FUEL IN IRON-PLATED SHIPS OF WAR.*

BY EDW. ELLIS ALLEN, A.I.C.E., M.I.M.E.

THE object of this paper is to point out the very great importance of economising the consumption of fuel in iron-plated ships of war, and to show how this may best be done. It is a subject which has been sadly neglected, notwithstanding these vessels have to be constructed to carry several hundred tons additional weight, even when only partially protected.

This increase of weight has been met to some extent by reducing the number of days' fuel carried; so that instead of these vessels coaling for fourteen days, which, in the opinion of most persons, is the least they should do, the quantity has been reduced to considerably less than one-half. With bad or indifferent coal this time would be reduced to perhaps four days consumption when full steaming, *i.e.*, when the engines are working up to say four times their nominal power. Moreover, the high rate of speed considered desirable for these vessels necessitates a corresponding increase in the power of the machinery, which of course, under any circumstances, involves an increase in the fuel consumed, or, in other words, reduces the time during which a given quantity of fuel will last.

Further, it is highly probable in future wars great despatch will be necessary in moving vessels from one station to another, not only from the fact that for many years to come there will be comparatively few iron-cased vessels in the navy, but also from the increased rapidity with which warlike preparations must be made. This also will tend to increase the quantity of fuel consumed.

Even in time of peace it will be difficult to reconcile ourselves to war steamers going far under sail alone; and when the whole of the working expenses of a large ship of war are taken into account, it may be the more economical course to put her in commission so many weeks later, and then let her steam to her destination. Indeed it cannot be doubted that the same causes which have operated in supplanting sailing vessels by steamers will also induce the use of the steam power more and more as time advances.

There are thus several important reasons why every effort should be made to economise the consumption of fuel in the ships of our new iron-plated fleet, viz.:—Additional weights, increase of speed and distance to be steamed, increased despatch in moving from station to station and of time during which steam power will probably be used, even under ordinary circumstances, and increase in the cost of coals, owing to the continually increasing size, power, and number of steam ships in the Royal Navy.

To these reasons for economising fuel we may add: The universal deficiency of boiler power in ships of the Royal Navy, necessitating a relative increase of space being allowed for this portion of the machinery; as also the fact, now generally admitted, that much smaller vessels than those first constructed will be necessary in order to constitute an efficient fleet; these small vessels being of course as thickly plated as the very largest, if not more so, on account of their speed being considerably less.

From the particulars given in the accompanying table, it may be stated with sufficient accuracy that in most of our iron-plated ships the weights of the three items, viz., the armour-plating, the machinery, and the fuel, are very nearly equal, and that together they constitute about one-third of the total displacement, *i.e.*, in vessels plated amidships only. Marine engines, of good construction, when working full power, exert a force when measured by indicator, considerably above their nominal power; and it is a rule with the Admiralty that all engines supplied to them shall work up to at least four times this nominal power. Now the average consumption of fuel in marine engines of the ordinary but best construction being about 4½lb. per indicated horse-power per

hour, it follows that a nominal horse-power requires about 4 cwt. of best coals in the day of twenty-four hours, so that a 1,000-horse power engine would consume something like 200 tons of coal per day when working full power. Comparing this quantity with that for which stowage is given in the iron-plated ships of the Royal Navy, it will be seen that the best of them carry no more coal than would serve them for about four days' full steaming.

We are, nevertheless, told that in all or nearly all cases, seven days' supply is provided, but this can only be on the supposition that the engines are not intended to work full power the whole of the time; indeed, with the ordinary boilers used on board war steamers, this is not possible, for it is well known that full steam cannot be kept for more than twenty-four hours together.

The very great increase of power necessary to propel any given vessel at an increased speed renders it a matter of some difficulty to obtain a rate of speed in the iron-cased ships such as that believed to be desirable, or rather necessary, by those competent to judge. If a certain power be necessary to drive any given vessel of good form at ten knots per hour, then to increase the speed of the same vessel to twelve knots will require nearly double that power; to increase it to fourteen knots the power must be nearly three times as great, and to increase it to sixteen knots the power will require to be more than quadrupled. The estimated speeds of our new ships of war, even in smooth water, are considerably less than those thought necessary *at sea* by naval men and many others, and the difference is as much as one and a half to two knots per hour.

Six of the largest vessels are estimated to attain about fourteen knots perhour; five of them about twelve knots; two of them about eleven and three-quarter knots per hour; four of them about eleven knots; one about ten and three-quarter knots; and one only nine and a half knots; and in the vessels tried even these speeds have not been attained; whereas fifteen knots per hour has been very generally assigned as the speed below which our new iron-plated ships of war should not be propelled when at sea.

In favour of such a speed we have the opinions of Mr. Scott Russell, Mr. Samuda, Captain Halstead, Commander Oldmixon, Admiral Moorsom, and many others.

With regard to the distance which such vessels should be able to go without recoaling, we have the most distinctly-expressed opinion of Mr. Scott Russell and Captain Halstead, as well as those who have commented upon their views, that 5,000 miles should be the minimum, whereas none of our ships could, with their ordinary supply of coal, go one-third of that distance.

With respect to the increased cost of coaling the ships of the Royal Navy, it will be found that the charge on this head is now over £300,000 per annum, and in war time more than double the ordinary amount is expended. What shall it be, even in times of peace, when a fleet of iron-cased ships of the "Warrior" class shall have been formed? We may indeed view with some alarm the amount of this item in the naval estimates of future years, unless something be done to diminish the consumption of fuel in marine engines.

Regarding the necessity of economising fuel in ships of war, on account of the insufficiency of boiler power at present allowed, it will be only necessary to quote the opinion of the present Surveyor of the Navy, expressed by him when in charge of the steam reserve at Portsmouth in 1858. He says:—"As far as my experience goes, no ship of any class or with any makers' engines has sufficient boiler space; there is not one of the multitudes I have tried that has steam enough to keep the throttle valve open for two hours. The steam drops directly the vessel goes over nine knots, and this not in one or two, but in all without exception. . . . Nothing is so wasteful of fuel as too small a boiler: intense firing and incomplete combustion of the fuel is the inevitable result of trying to keep up steam in such a case. . . . Not a step is made in the right direction of obtaining speed and economy until more attention is paid to the proper proportion between the quantity of steam used in the cylinders at each stroke, and the quantity remaining in the boiler."

He says that 600-horse boilers should be used where 450-horse power boilers are now employed, and the ships would go faster, not perhaps rush past the measured mile quicker, but in a chase of four or five hours.

The Committee on Marine Engines, reporting upon this and other evidence, observe:—"From the evidence taken by the committee it appears that in general the boilers supplied to our men of war are deficient in generating steam, and that full speed in consequence can only be maintained for a short time. Now, the remedy of that defect must necessarily involve the whole question of the amount of space that can be allotted to the boilers; the committee, therefore, consider that they need not enter into further details, and that they do their duty by simply, and without comment, bringing the question before their Lordships."

Of the last reason named for encouraging economy of fuel, no better illustration can be given

* Read before the British Association, Section G, August, 1862.

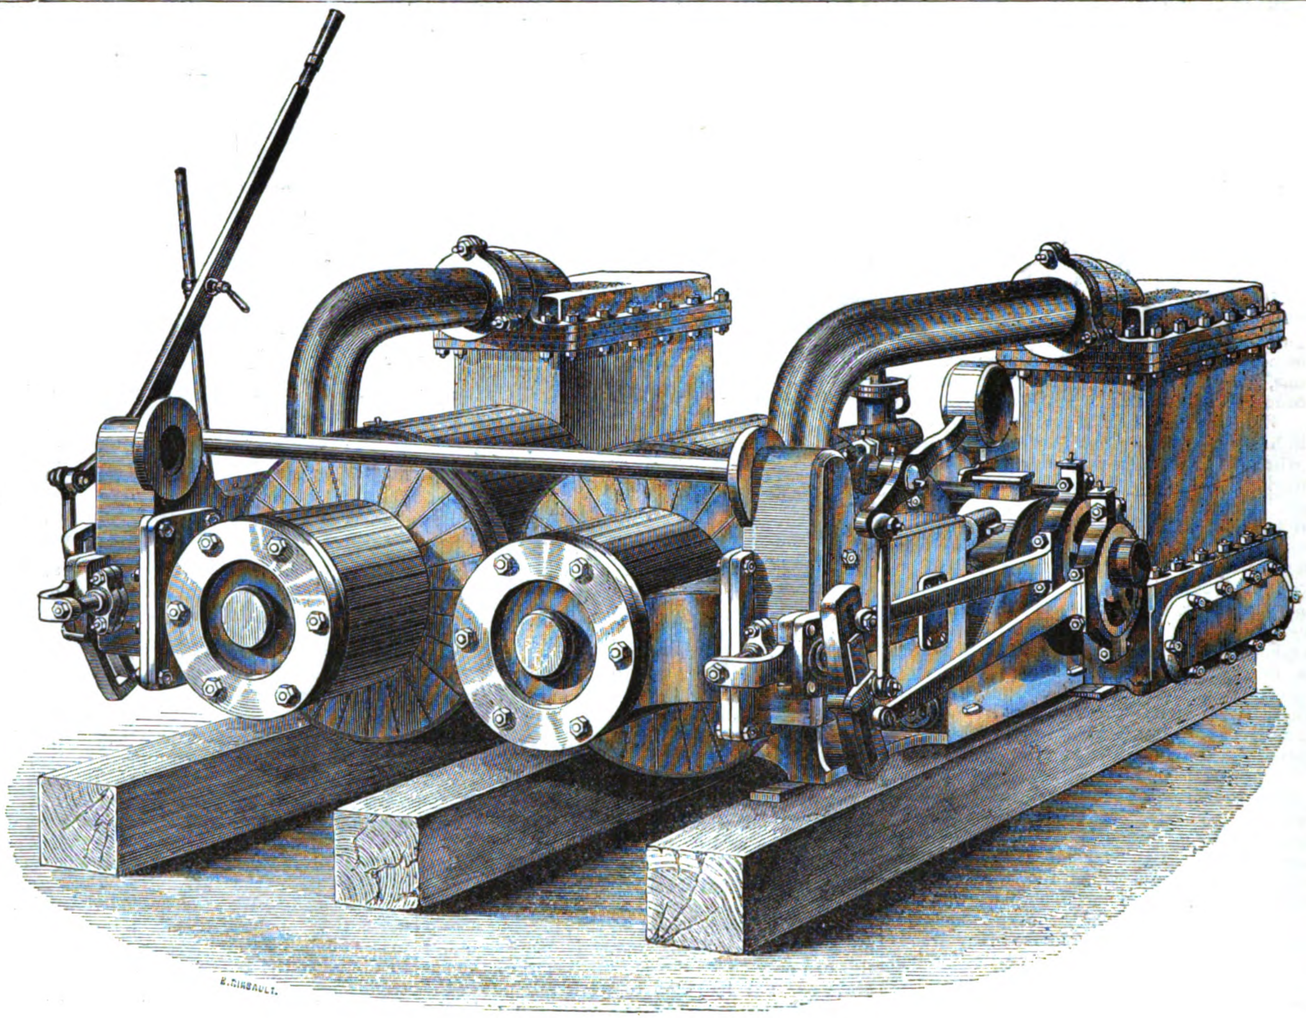

FIG. 1.

than that of the "Enterprise," the first small ship in course of construction by the Admiralty plated with armour. In this case the employment of ordinary machinery (excepting having surface condensers), not only necessitates the quantity of fuel taken being reduced to a very few days' steaming, but the speed with which we are to be satisfied is an "estimated" one of nine and a half knots only. What will this be as an average at sea? Possibly not over eight knots.

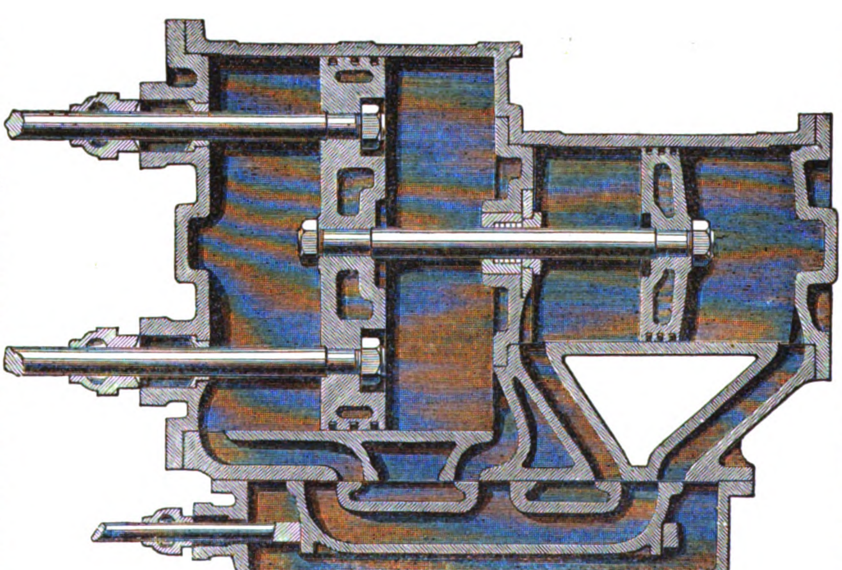

FIG. 3.

Enough has now been said to show that economizing the consumption of fuel in iron-plated ships of war is a subject of the very gravest importance; and although this will be admitted generally, and, perhaps by none more readily than the authorities of the Admiralty, it appears practically to have received far less attention than it deserves. It is hardly saying too much when we state that coal is the only item in which weight can be saved.

It has been long known that many vessels in the merchant service have been working now for some years upon just one-half of the fuel consumed in ships of the Royal Navy. In proof of this, although evidence is abundant, I shall give simply the opinion of Mr. Charles Atherton, late Chief Engineer of Woolwich Dockyard, and that of Mr. Andrew Murray, Surveyor to the Board of Trade. Mr. Atherton, in a paper read at the British Association, three years ago, says, "I believe the ordinary consumption of fuel in steam ships of the Royal Navy is fully 50 per cent in excess of the amount of 2½ lb. which has been practically realised on continuous sea service."

Mr. Murray, in his paper on "Means and Appliances for Economizing Fuel in Steam Ships" (read in March, 1860,) says: "It is hoped and believed that the day is not far distant when the average consumption of marine engines will be reduced to nearly one-half of what it now is. In Cornwall, ninety millions of pounds raised one foot high in an hour by a bushel (or 94lb.) of coal is considered fair work for a good steam engine, which corresponds to nearly 2¼ lb. of coal burnt per indicated horse power per hour. It is not likely that this degree of economy can ever be permanently maintained *at sea;* but if our marine engines can be induced to content themselves with 3 lb. or even 3½ lb., this will still be a vast improvement on their present average consumption." What this is he states in his work on "Steam Ships" in these words:—"The more usual consumption of modern marine engines varies from 4 lb. to 5 lb. per indicated horse power per hour, and the average consumption of all classes cannot be less than 6 lb.

It may be here observed that the Admiralty returns contain no statement of the consumption of fuel of ships of the Royal Navy; but this omission having been complained of for many

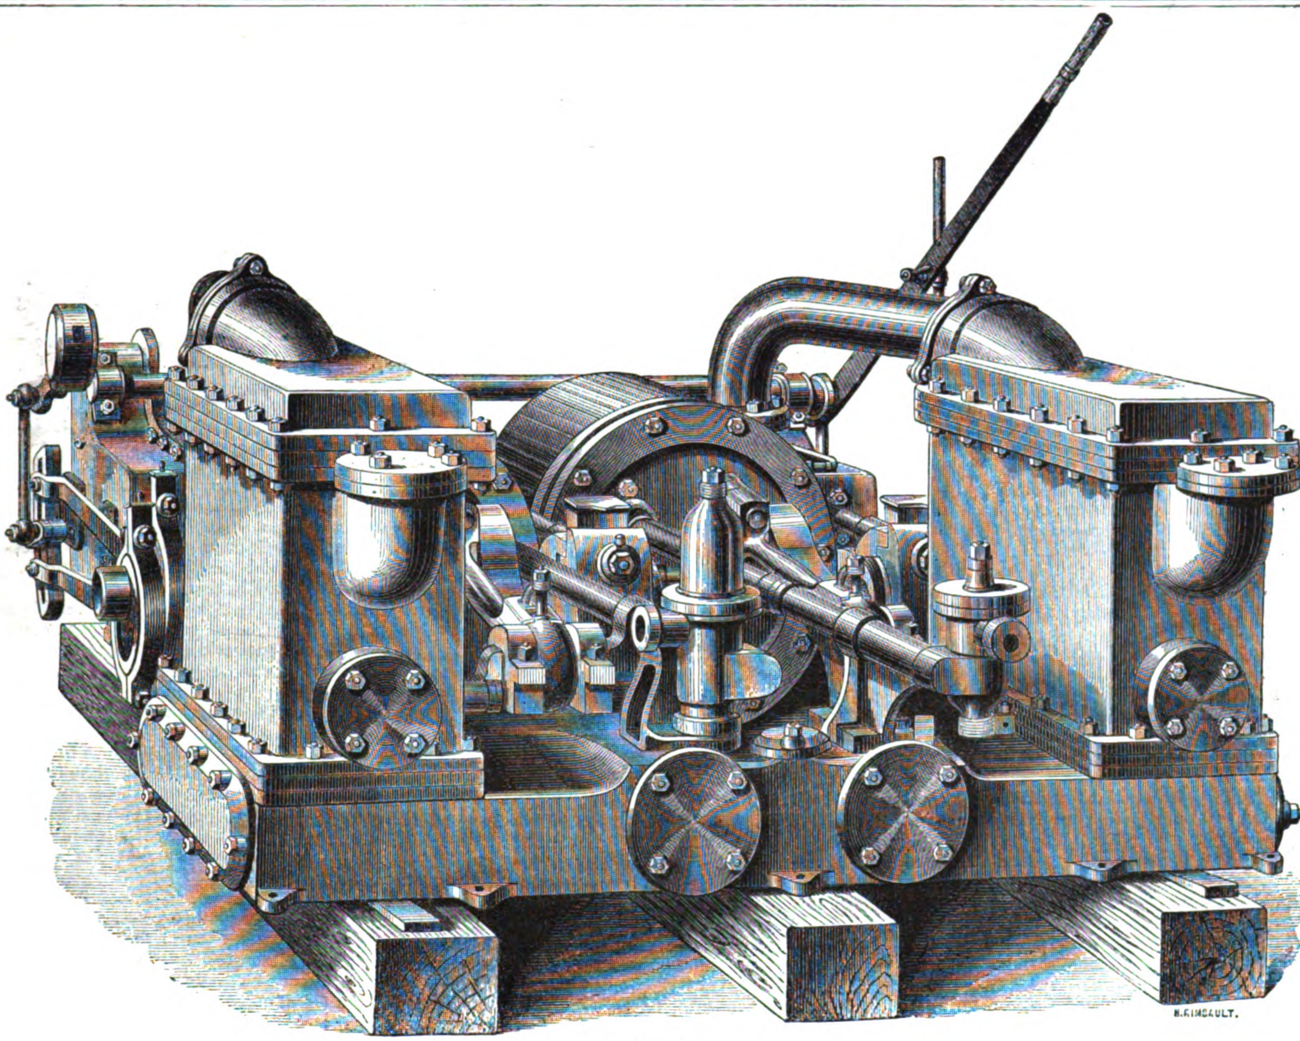

FIG. 2.

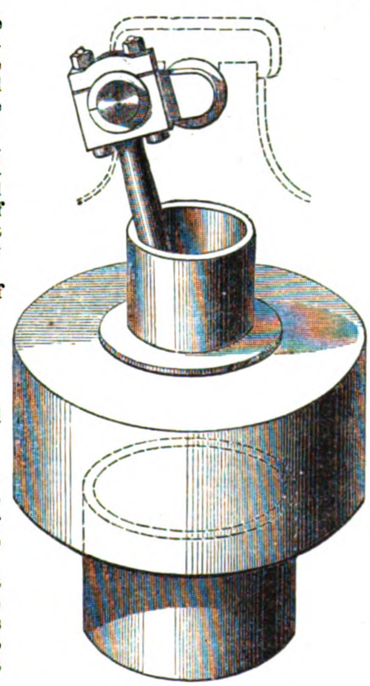

FIG. 4.

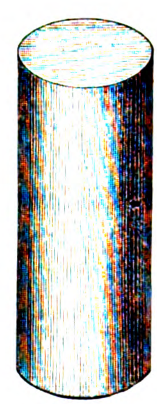

FIG. 5.

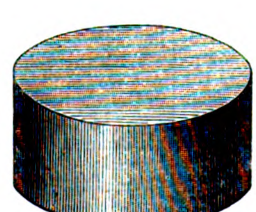

FIG. 6.

years past, the Committee on Marine Engines recommended that the consumption of coal per indicated horse power, as well as the quality of coal and evaporation of water, should be given in future.

The fact of vessels running continuously on half the fuel consumed in Government vessels is now well known, as are also the principles of construction on which this important saving is made. They may shortly be stated as follows:—

1st. Proportionate increase of boiler power.
2nd. Expansion of the steam to, say 5 lb. pressure.
3rd. Jacketing the cylinders.
4th. Superheating the steam.
5th. Condensing by surface instead of by jet; and
6th. Heating the feed water.

And all this may be done without increasing the pressure of steam above 20 lb. or 25 lb., although the higher the pressure of steam, the greater the economy of fuel.

It is difficult to assign the exact proportionate value of each of these six modes of economising fuel, as they have seldom, if ever, been so far separated as to admit of correct deductions; but, taken altogether, there is now no doubt that *fifty per cent.* may be saved in the ordinary consumption of fuel. This saving has been practically effected in several vessels where the principles above stated have been carried out.

In the early part of 1855 I read two papers at Birmingham on "The Commercial Economy of Expanding Steam in Marine Engines," and described several new forms of engines suited to this purpose, and, ever since that time, have endeavoured to direct the attention of steam-ship companies and owners, as well as that of the Admiralty, to the subject.

In 1858 I sent detailed drawings of engines to the Admiralty, the designs being made with a view to effect a very large saving in fuel. One of these was that of concentric cylinders, with three piston rods and cross head, the two outer rods being carried to a guide block, from which the connecting rod was returned to the crank; this arrangement being precisely that adopted in the Swedish gunboats, and for which a medal has been awarded to the maker in the Exhibition.

In the early part of the present year I again addressed the Admiralty, calling their attention to this subject, and requesting the favour of an examination of the engines constructed on my patent of 1855, by Messrs. J. and G. Rennie, and which may be described as double expansive end-to-end cylinders, the small cylinder being placed at the back of the large one, motion being communicated to the crank by means of double piston rods (Figs. 1, 2, and 3.) Even this arrangement has, it appears, been recently tried on one of the Swedish vessels of war, the results of working being, it is said, very satisfactory. If, therefore, the Swedish engineers have not the faculty for designing economical marine engines, they may, at least, take credit for duly appreciating what others do, and in this respect are considerably in advance of some of

the engineers of our own country. In these several applications to the Government, the object was to show how the expansive principle could, in my opinion, be best carried out in ships of war, fulfilling the necessary conditions of such vessels, *i.e.*, of keeping the weights down as much as possible and the machinery below the water level.

I showed, in my papers, that the suggested alterations in marine engines could be made without either adding to the gross weights carried or to the space occupied in the ships, and that a very considerable saving of coal would be the result; increased capacity of cylinder to allow of full expansion of the steam being, of course, under every possible arrangement absolutely necessary.

One of the forms of marine engines suggested by me in 1855 has lately been adopted in the case of the Poonah's engines, now building by Messrs. Humphreys and Tennant, the small and large cylinders being placed end to end, as above described, with reference to the engines made by Messrs. Rennie, but motion being given to the crank shaft by means of a trunk working in the large cylinder. (Fig. 4.)

For these several form of double expansive engines may be claimed many advantages, which are shortly these:—

1st. Capability of fully expanding the steam without the use of expansion gear.

2ndly. Great uniformity of motion by reason of the steam from the boiler acting upon a comparatively small area, not pressing upon the large pistons until partially expanded.

3rdly. Saving of considerable weight on account of the strength of the connecting rods, piston rods, &c., being only necessarily proportioned to the pressure of the initial steam on the small piston and the expanded steam on the large area; instead of the initial steam on the latter; or, rather upon a considerable extension of it, as in the case of a single acting cylinder designed for great expansion, its area must be greatly increased, the stroke not being capable of being lengthened.

4thly. Considerable saving of steam owing to the loss in clearances in the small cylinder being made less than that in a very large cylinder, the loss in the latter case absorbing a large percentage of the steam.

5thly. The cylinders being in line with each other no increase in the number of piston rods, connecting rods, or guides are necessary.

6thly. That, practically, all the advantages of a long-stroked engine are obtained without increasing the stroke, and which cannot be done owing to the speed of revolution of direct acting screw engines being necessarily high.

And 7thly. That by fully expanding the steam, a far less quantity suffices for the production of a given power, this allowing of the boilers being reduced a third or a fourth, still leaving a large proportionate increase in boiler power compared with the steam required.

It will be readily admitted, on all hands, that very considerable difficulties would be found in making ordinary marine engines fully expand their steam, an increase in the capacity of the cylinder of from two to three times being essential.

At present the shape of the cylinders of marine engines approaches to that of those of rivetting machines, their diameter being frequently 2½ times the stroke; whereas in pumping engines, in which economy is studied, the cylinders assume an entirely different form, their lengths being three times their diameter, as shown in figs. 5 and 6, which represent cylinders of the same capacity, the former similar in shape to those of the 1,350 H.P. engines constructing for the largest iron-plated ships, and the latter the cylinder of an ordinarp pumping engine. Indeed all engineers admit that, in very short cylinders, *i.e.*, single-acting ones, economy is out of the question. It is, therefore, greatly to be regretted that, in our iron-plated ships, even in those of the largest class, the same form of engines has been adopted as was employed fourteen years ago, notwithstanding Mr. Atherton, the late engineer at Woolwich Dockyard, recommended some years ago that "double expansive engines ought to be tried," especially as superheating of the steam had been carried out.

Mr. Murray has rather severely remarked upon "the plan adopted by the Government of contracting for their steam machinery with only a few favoured and old-established houses," and states that this, "though perhaps justifiable in other respects, has undoubtedly tended to promote conservatism in marine engines, and to repress innovations and improvements. . . . . competition being scarcely roused into action. . . . . . In the case of those manufactures, ... however, who are dependent upon the custom of the great steam shipping companies, and other private owners of steam-vessels, who have a strong interest in this question, there exists an active competition, and, consequently, a powerful inducement to improve upon the economical performance of their machinery. We find, accordingly, that it is this class who have taken the lead in the steam reformation which has recently set in."

The practicability of saving so great a percentage of fuel being now so well known, how is it that the whole of our iron-cased fleet at present in existence or ordered, are doomed to consume double the amount of fuel which is necessary?

In the twenty-six iron-cased ships constructed and constructing, a force of no less than 18,310 nominal horses power is to be employed; and when working full power, *every day* will witness an unnecessary consumption of upwards of 1,700 tons of coals, which, on foreign stations, would certainly amount to more than £5,000 sterling.

This loss is, however, not what is to be most regretted; but rather the fact that our iron-cased fleet, the largest vessels of which are to cost upwards of £350,000 each, and are provisioned for four months, should only carry coals enough for from four to five days' steaming. It is surely a sad pity that these vessels should have to creep into port every time after steaming, say 2,000 miles, or else waste days, and perhaps weeks, of valuable time on full commission pay, in attempting to reach their destination by the use of sails?

If it be maintained that the quantity of coals carried is sufficient—which, I think, the Admiralty authorities would hardly acknowledge—even then is it not better to increase the armour plating, or the speed of the vessels, by reducing their draught or increasing the power of the engines, rather than carry an unnecessary quantity of expensive fuel?

It is now certain that the speed of the "Warrior" and "Black Prince" is much below what was anticipated. And even if a speed of fourteen knots were obtained, under the most favourable circumstances of clean bottom, clean tubes, and fair weather, this would be reduced to about twelve knots at sea, running days together; and this is no less than three knots below the speed that has been considered necessary.

Again, if the present quantity of fuel carried be enough, the engine power could be increased some 40 per cent. without increasing the draught of water, and still allow of the same number of days' fuel. This increase of power would increase the speed about one knot and a half per hour, which cannot be regarded as a matter of slight importance.

With these facts before us, the question arises, Are we justified in continuing to employ engines of the ordinary kind in our iron-plated ships of war? In considering this matter we must be careful not to confound the excellency of workmanship of Government engines, which is all that can be desired, with correctness in the principles upon which such machinery is made and worked.

The wasteful expenditure of fuel in all vessels having ordinary but first-class machinery, arises, of course, from the principles upon which it is made and worked being faulty; such as filling the cylinders three parts or seven-eighths full of steam, and only expanding in the remaining space; condensing by jet; not super-heating the steam or heating the feed water; confining the boiler space in proportion to the steam used (although this space is much greater than required under improved conditions); not jacketing the cylinders; and, finally, using short-stroked single expansive engines.

No amount of excellence in workmanship can ever make up for this total disregard of every principle which experience has shown to be necessary to economical working.

Our present navy consists of vessels in which there is a nominal power of upwards of 142,000 horses, distributed in about the following proportions:—

	Horse-power.
Ships in commission	60,000
Do. in ordinary	51,000
Do. used as transports, &c.	13,000
Do. (new iron-plated) and batteries	18,000
Total	142,000

The ultimate extent of our iron-cased fleet, of course, is not as yet known, but taking the very moderate estimate made by Mr. Scott Russell, we have yet engines to provide to the extent of, at least, 60,000-horse power, making a gross power of 200,000 horses.

Assuming that one-half of these vessels are in commission in time of peace, the *daily* consumption of coal when working full steam would be over 15,000 tons at the present rate per indicated horse power.

Now ships in commission may be fairly assumed to be one-third of their time under steam, say two days per week, or 100 days in the year. They will probably be half this time under easy steaming, and the remainder three-quarters and full steaming, and will consume from 2½ to 3 cwt. of coal per day, or 14 tons per annum per nominal horse power, or for the whole of the ships in commission about 1,400,000 tons per annum.

This is, then, what we may look forward to in the navy returns in future years of peace, *i.e.*, if the present consumption of fuel be maintained. It is just half this quantity, which experience has now fully proved, may be saved by a modification in the mode of constructing and working marine engines, and it is to the cost of this quantity, which could be saved, and the advantages arising from its absence in the vessels, that attention is now invited.

Applying the same calculations to the engines of the twenty-six iron-cased vessels made or ordered, or omitting the floating batteries and some of the vessels in ordinary, it appears more than probable that had these vessels been fitted with improved machinery, a *money* yearly saving would have been made sufficient to purchase at least one iron-cased vessel annually, from saving in the consumption of coal. This again, it must be remembered, is quite distinct from the other numerous advantages which have been referred to, and of which no estimate can be made; the very existence of the ships being perhaps jeopardised by either want of coal or want of speed.

This saving of fuel, whenever brought about, will, without question, give us one or other of the following advantages, *in addition to the money saving*, viz.:—

Increase of armour plating, 50 per cent.; or,
Increase of speed to the extent of one knot and a half; or,
Increase of number of days' fuel to double what it now is; or,
Diminished draught to the extent of 8 in. to 12 in., according to the vessel,

thus enabling us to have armour-plated vessels of comparatively very small tonnage.

To all this we must not forget to add the loss of time, expense, and inconvenience of frequent coaling when only five to six days' supply are carried; and, again, the cost and labour of trimming the coals, and feeding the furnaces with double the quantity which would be needed with good double expansive engines.

It is hoped that these considerations will induce the Lords of the Admiralty to turn their attention to the advantages of working steam expansively in the vessels of the Royal Navy, not simply as it has hitherto been done,

and when the power is proportionately diminished and no saving effected, owing to the machinery not being adapted for expansive working, but constantly and regularly in ordinary working and under proper conditions, when its advantages would be at once experienced.

In conclusion, it is only fair to mention that soon after the appearance of the report of the Committee on Marine Engines, recommending that the number of contractors for Government engines should be increased, and that the best engines should be adopted in ships of the Royal Navy, by whomsoever proposed to be supplied, orders were issued for three pairs of engines, designed to work with less fuel than usual. Messrs. John Penn and Son supplied a pair of large trunk engines, with surface condensers; Messrs. Maudslay a three-cylindered arrangement, also with surface condensers, designed by Mr. Sells; and Messrs. Randolph and Elder a six-cylindered arrangement, also with surface condensers.

Neither of these vessels have as yet been fully tried, the results, however, being anxiously looked for by engineers.

Considering the nature of these three plans, which, with the exception of the trunk engines, involve considerable complexity, the trunk and three-cylinder arrangements being, moreover, single expansive engines, it is very doubtful if the results can be altogether satisfactory; and certainly cannot be so far so as to warrant experiments stopping at the point at which they have now arrived. Trials should at least be given of such other arrangements as appear likely to give favourable results.

The double-expansion end-to-end cylinder engines proposed by me in 1855, for ships of war, having now been very ably worked out by Messrs. J. and G. Rennie, and, it is understood, been favourably reported upon by the inspecting engineer of the Admiralty, who was instructed to examine them. It is hoped an opportunity will shortly be afforded of testing their suitability for her Majesty's ships; the success of the principle of double expansion being already fully established, and Messrs. Rennie being prepared to guarantee to the Government that the consumption of fuel shall not exceed 2 to $2\frac{1}{4}$ lb. per indicated horse power per hour, or half the ordinary consumption. To the general introduction, however, of so radical a change in the construction of marine engines for the ships of the Royal Navy, a thorough conviction of the importance of economising the fuel seems essential, and it is hoped this will be found to have been somewhat promoted by the present paper.

ANTI-FOULING OF SHIPS.

SINCE 1845, says the *Times*, when experiments with protecting and anti-fouling compositions for the bottom of iron ships commenced at Blackwall, on Her Majesty's screw yatch "Fairy," with the compositions of Baron Wetterstedt, Mr. Owen, and Mr. Ditchburn, up to the present time, when the preparations of Mr. Hay, M'Innes, and Peacock, and Buchans, are those exclusively applied to sea-going vessels in her Majesty's navy, not one has been found to answer in all the necessary requirements. Many of the compositions tried have not only failed to prevent the adhesion of foreign matter to an iron ship's bottom, but have actually, or apparently, assisted the formation and growth on it of marine incrustations. The composition prepared by the Admiralty chemist, the chief ingredient of which is oxide of copper, and which, according to the official reports from Malta and the home dockyards, stands first on the list for its preservative and anti-fouling properties, does not altogether prevent the growth of weeds or the attachment of shells to the bottom of a vessel on service in a tropical climate. For the new patent composition of Mr. Hay, he claims a great superiority in anti-fouling properties over the ordinary composition in use, but this has not yet been tested fully on the bottom of any sea-going vessel. As the "Himalaya," which is coated with Peacock's and Buchan's composition, will be again placed in the dock adjoining that in which the "Megæra" is, an opportunity will then exist for comparing the three compositions. The serious damage which has been inflicted upon the bottoms of iron ships coated with anti-fouling compositions, when on lengthened foreign service, by the destruction of the composition and subsequent corrosion of the plates and rivet-heads, together with the necessity for meeting the threatened want of increased dock accommodation for our iron ships as speedily and effectively as possible, has induced the Admiralty to devote their immediate endeavours to find some means to render this docking of iron ships for cleaning and re-coating their bottoms as seldom requisite as possible. Mr. Griffiths has laid before the Admiralty a plan for sheathing the bottoms of iron ships with Muntz metal, using a non-ducting material between the protecting metal and the iron-bottom plates, and has received an order to sheath a small iron vessel on this plan as an experiment. The Controller of the Admiralty has also called upon Mr. Hay, chemist to the Board, to send in to the Admiralty a model of his proposed plan for sheathing the bottoms of iron vessels with copper or Muntz metal. This plan was first submitted to the notice of the Admiralty on the annual visit of the Board, with Lord Auckland at his head, some years since, and was discussed by the Board on their return to London, but its adoption was declined. The decision had just then been arrived at that iron ships were quite useless as men of war or Government screw troopships, and that it was even desirable to get rid of the very few that then were on the navy list. Other plans besides those of Mr. Hay and Mr. Griffiths are also before the Admiralty, all seeking to attain the same end, although by different means, several resorting to the process of electrotyping in preference to either applying temporary compositions, or the ordinary method of protecting wooden ships by sheets of copper. The two more prominent of these last are known as the "Besley" and "Walen" processes. Both profess to deposit a pure metal, or a combination of metals, by an alkaline process in lieu of the old acid process. The Besley process is already partially adopted by the Admiralty at Portsmouth, tanks and batteries now being at work over the steam factory of Portsmouth Dockyard, depositing a coating of metal on the iron bolts that are to be used for fastening the armour plates on the sides of the "Royal Alfred" and "Royal Sovereign." The success as yet has not been great; in fact the alkaline process as developed by the Besley system is, owing to some cause, slow, and may possibly yet be superseded by the original acid bath. The Walen alkaline process is represented by the floating dock in the Victoria Docks, and its effectual success there seems to be placed beyond a doubt. Mr. Walen claims, as the merits of his invention, that he can rapidly precipitate a pure metal, or a combination of metals, upon iron of any uneven form, with a perfectly even and bright surface, of any thickness, and indestructible as the metal upon which it is deposited. Mr. Walen, while proposing very much that is evidently simple and practicable, and which will doubtless be carried out with but little delay, relative to the preservation of our iron ships in their construction, goes much further than this, and advocates the adaptation of one of the new docks now constructing as a hugh bath, in which an iron ship, when delivered to Government by the contractors, might be at once received, and coated as far above the water line as required, by one process, with an imperishable covering of copper or other protective metal. Whether all or any of these plans should be definitively adopted by the Admiralty time and experience can alone decide.

EXPERIMENTS WITH ARMSTRONG AND WHITWORTH FIELD GUNS.

(From the Daily News.)

SOME very interesting trials of 12-pounder field-guns, rifled according to the different systems of Sir William Armstrong and Mr. Whitworth, were made at Fort Twiss, near Shorncliffe, last week, before General Bloomfield, inspector-general of artillery, and a large staff of officers. The Whitworth guns were four in number, and formed part of a battery of 12-pounder brass muzzle-loading guns, being the first guns rifled on this system which have been furnished for the service. The Armstrong guns were two of the ordinary 12-pounder field-guns, such as were used in China, with certain improvements since adopted, and of course breech-loaders, made of iron on the plan employed in the construction of all the Armstrong guns.

This was the first occasion on which so direct a comparison has been made between these rival systems in regard to field-guns, and the result was regarded as one of considerable importance by the officers of Artillery and other scientific artillerists present at the experiment. The trials began by firing at a floating target distant 500 yards. As the shot fell in the sea no very close comparison could be made as to the accuracy of the respective hits, but both at the 500 yards range and afterwards at the 1,200 yards, the shot from the Whitworth was the first to carry away the flag aimed at, and it was generally conceded that at both ranges this gun fired closer to the mark than the Armstrong. Both guns were then tried with shell, the Armstrong firing the compound percussion shells, the Whitworth firing the new kind of shrapnel perfected under the superintendence of Colonel Boxer, who has been permitted to give all the assistance his great knowledge and experience afforded in advancing Mr. Whitworth as to the construction of this new projectile, which is now promising so far to suppass all shells hitherto invented, whether for the field or for piercing the sides of armour-plated ships. It was observed that considerable number of the Amstrong shells burst in the air before reaching the mark, and of course without effect; but the Whitworth shell, being used with a time-fuse, which is ignited in front like the old shell by means of the ordinary Boxer time-fuse, was found to be more regular and effective in its action. The complicated apparatus contained in the Armstrong shell for obtaining ignition by percussion is dispensed with, and consequently the projectile is a much cheaper, and what is more important, a more certain weapon. The mode in which the new shrapnel acts is, that at the required moment, ascertained precicely by knowing the distance of the object, the shell bursts by the burning out the fuse, the charge of bullets is dispersed. The end or front of the shell is blown off, and from 40 to 50 bullets and pieces of iron, all of a size large enough to be highly destructive, are scattered in every direction. When this shell is fired at long ranges, as it would be on entering into action, the iron case is not completely broken up, and the larger portion acts as a solid shot, continuing in its course, or, perhaps, smashing a gun carriage, or striking the gun so as to disable it. The Armstrong shell is burst on striking the object into as many as 217 fragments, all small, and many of very small size. So that if it were partially buried in striking the ground much of its destructive power would be thrown away. If the new shrapnel shell is required to be used at short range the case is easily burst completely by increasing the bursting charge of powder. A few of them on this occasion burst short of the mark, but on the whole the practice was considered to be very good, and entirely confirming the anticipations of the inventor, Mr. Whitworth. But perhaps the most interesting part of the experiments was a comparison made between the two different kinds of ordnance as to rapidity of fire. It has always been held that the one great advantage of the breech-loader was its superiority in handiness and quick firing. The result of this trial does not, however, confirm this opinion. The artillery-men were ordered to fire twenty round shots from each gun as rapidly as they could be served. The Whitworth gun finished the twenty rounds first, completing the task in thirteen minutes: the Armstrong followed $2\frac{1}{4}$ minutes later. This superiority was attributed to the simplicity of the

loading and serving the Whitworth gun, the drill being, in fact, precisely the same as in working one of the old smooth-bore guns, whereas the Armstrong drill requires three or four extra movements. All the guns were further tried by firing from each 100 consecutive rounds. The Armstrongs were fired with lubricating wads, and were also washed out and had their breech pieces changed as often as they became heated so as to be unsafe; the Whitworths all completed their 100 rounds without being washed out at all, and without using any lubricating wads. It was remarked, too, that the loading was as easy at the last round as at the first.

The trial exhibited a practical proof of the value of brass muzzle-loading guns. The French artillery, it will be remembered, have always preferred these guns, as they are found very rarely to get out of order, either by injury in service or by the action of the weather. When rifled, as these guns were, upon the Whitworth system, and made without the complicated arrangement for loading at the breech, it is evident that they are capable of the most efficient service of any field-gun yet employed.

MODE OF APPLYING THE ELECTRIC LIGHT FOR MINING PURPOSES.

By MM. DUMAS AND BENOIT.

THE apparatus consists essentially of three parts—a battery, a Ruhmkorff's coil, and a Geissler's tube—the whole arranged so as to produce a sufficient light to illuminate the miner, and allow him to work in atmospheres where other lights fail.

The light produced is cold, or rather does not heat the tube in which it is produced; and gas has no access to it: it is quite isolated. The apparatus is as compact as ordinary lamps, and there is no injurious emanation. It can be lighted or extinguished at will. It can work for twelve consecutive hours without diminution, and without requiring any change. The workman has only occasionally to agitate the carbon by means of a rod.

The greatest difficulty consisted in being able to associate a battery of such intensity that the weight of the apparatus was as small as possible, the light produced of the greatest regularity, and its duration at least twelve hours. The present form of the apparatus, which may be still further diminished, is already so small that the miner can carry it without inconvenience, like a small carpet bag.

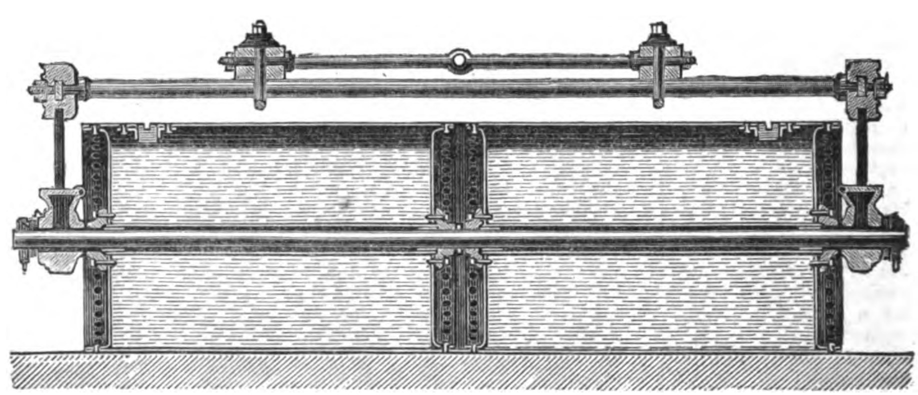
The authors point out the advantages of such a mode of illumination, and state that the results obtained in using Becquerel's fluorescence-tubes have led to the expectation that the luminous effects may be greatly improved both as to duration and intensity.—*Comptes Rendus*, September 8, 1862.

A COMPRESSING AIR PUMP.

AT the last meeting of the Manchester Philosophical Society, a paper was read by Dr. J. P. Joule, entitled, "Notice of a Compressing Air Pump." The author referred to the difficulties of realising in practice the theoretical advantages of the air, or the super-heated steam engine. The abrasion which takes place when metal rubs against metal, without an intermediate lubricator, speedily destroys the cylinder. He believed that the necessity of using elastic packing would not exist if the length of the channel along which the elastic fluid must pass, in order to arrive at the opposite side of the cylinder, were sufficiently increased. This might be accomplished by increasing the depth of the piston, or by placing on the rim of the piston concentric rings to enter, at the beginning and end of each stroke, corresponding concentric grooves in the covers of the cylinder.

The principle of great depth of piston, as a substitute for packing, had been successfully carried out in the pump which was the subject of this communication. The cylinders, two in number, are twenty inches long and two inches in diameter. The pistons are solid cylinders of

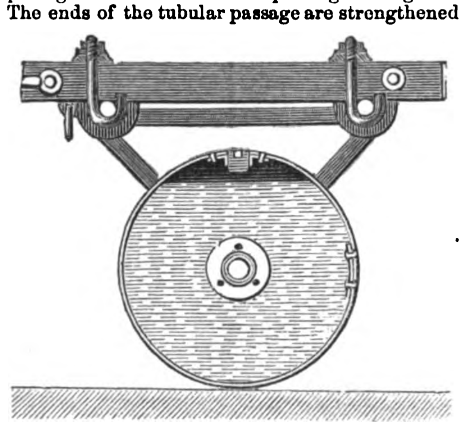
BARFORD'S IMPROVED LAND ROLLERS.



iron, ten inches long, fitting as accurately to the cylinders as is consistent with freedom of motion. The depth of each piston, as compared with its diameter, renders the usual guide or parallel motion unnecessary, so that the connecting rod is simply jointed to the top of the piston. Air is readily compressed to sixteen atmospheres, the quantity passing the sides of the cylinders being very trifling.

BARFORD'S IMPROVED LAND ROLLERS.

THE engravings represent sectional views of an improved land roller recently patented by Mr. W. Barford, implement maker, of Northampton. This invention has for its object the improvements in rollers for rolling land. For these purposes in constructing a roller (whether consisting of one or more cylinders), in order that the same may be weighted with water more advantageously than heretofore, each roller or section of a roller is closed at its ends, the ends being connected by a suitable tube or hollow passage to allow of the axle passing through it. The ends of the tubular passage are strengthened



or bushed where they receive and turn on the axle. The cylinder or cylinders used in constructing a roller may be of wrought or cast iron, and such is the case in respect to the ends or covers. These parts are put together water-tight, and such is the case in respect to the tubular or hollow passage which connects the two covers or ends of a roller or of a section of a roller. Each roller or section of a roller has an opening in it through which the supply of water is introduced, and such opening is closed by a screw plug or by other convenient instrument. By these means each roller and section of a roller consists of a vessel closed at each end, with a hollow passage through the centre thereof, whereby the supply of water introduced for adding weight thereto may rise above the axle, and even fill the roller or sections of which a roller is composed.

INCRUSTATION AND SCUM PIPES.*

THE number of boilers under inspection which suffer from incrustation is very large; indeed, to escape this inconvenience is quite exceptional. It forms a considerable impediment to satisfactory inspection, since it renders it difficult to ascertain the actual condition of the plates; it sometimes gives a delusive appearance, and leads to undue suspicion of corrosion, but more frequently it conceals defects, since corrosion is often found to be going on under, and to be caused by, the deposit.

In addition to the waste of fuel occasioned by incrustation, the wear and tear of boilers is considerably increased, apart from the effects of over-heating. Thus internally double-flued boilers suffer from the undue longitudinal expansion given to the furnace crowns, which increases the tendency to groove at the front end plate, an action always more or less developed in these boilers, while incrustation renders the use of tubular boilers altogether impracticable in localities not supplied with good water, and thus prevents the more general use of this economical class of boiler.

Although the danger of allowing incrustation to form on plates exposed to the action of the fire is too fully appreciated to need remark, the fact is not so fully recognised that even where no actual cake of deposit is formed, overheating frequently occurs. It is thought that this may, in many cases, be due to the presence of thickening matter held in suspension in the water, and it would be interesting to ascertain by experiment whether the impediment thus presented to the free escape of the steam does not—where the circulation is imperfect, or no such agitation of the boiler takes place, as in locomotives when running—lift the water off the plates, and thus cause overheating. Of the fact of overheating occurring where no incrustation is formed, and with an ample supply of water in the boiler at the time, there is no doubt, instances are constantly coming under notice, and it may be added that they are chiefly found to take place in boilers externally fired.

Apart from the injury done to the boilers from incrustation, a considerable amount of earthy matter passes over with the steam into the engines, and thus renders necessary the use of an increased amount of tallow for the piston and slides. This, though too frequently lost sight of, is illustrated by the fact that where boilers are fed from brooks, subject, on heavy rains, to sudden torrents which stir up the mud, the engine attendants are in the habit, at such times, of taking the precaution of giving the engine cylinders an extra amount of lubrication, finding the pistons, &c., to clog when this is neglected.

Under ordinary circumstances, the most practical plan for the prevention of incrustation is the adoption of an efficient mode of "blowing-out," and not the use of "boiler-compositions." To blow out, however, from one point only, at the bottom of the boiler, which is the general custom, has but a very limited and local effect. This is frequently remedied by the adoption of a perforated pipe, which is connected to the ordinary blow-out tap, and carried along the bottom of the boiler from one end to the other. These are technically termed "Topham-pipes," from the name of the patentee, and are generally spoken highly of by those of our members who have adopted them. They are, however, more successful where the sediment being heavy and sludgy falls to the bottom, rather than where it is of a lighter character, which frequently forms the hardest and most tenacious scale.

From the rapid ebullition that takes place within boilers when under steam, it is found that a greater part, if not the whole, of the sediment, set free by evaporation rises to the top of the water, forming a

* From the Monthly Report of the Manchester Association for the Prevention of Steam Boiler Explosions.

coat of scum, before finally depositing itself upon the furnace tubes or shell; and thus the readiest way of preventing incrustation is to blow out this layer of scum from the surface of the water by means of a scum pipe, before it has an opportunity of settling. There is nothing new or experimental in this, the system has been for years adopted with marine boilers, and there is no reason why its use should not become equally general with stationary ones. Many of our members have already tried it with considerable success, and find, on opening their boilers after a month or six weeks' work, that where they used formerly to be coated with a heavy muddy deposit they are now perfectly clean.

The following is an explanation of the description of pipe adopted:—It is about three or four inches in diameter, having a wing cast to it on each side, so as to form a trough throughout the entire length of the pipe. This pipe is carried within the boiler, from one end to the other, being made in any convenient lengths for introduction at the manhole; it is perforated with small holes on the top all the way along, the aggregate area of the whole number of these holes being equal to that of the pipe itself. The top of the trough is fixed a few inches below the level of the water, so that the scum on the surface may flow over it, when, being guarded from the disturbance of the ebullition, it deposits in the still water above the trough the sedimentary particles held by it in mechanical combination. A tap is fixed to the front end plate of the boiler in communication with this pipe, by means of which it can be blown out as frequently as is desired, which should not be less than once every two hours, when ebullition is going on. This tap, which need not be more than two inches in diameter, should be entirely of brass, fitted with a gland, and have a neat waste pipe attached, which may be of wrought iron, while also the waste pipes from the glass water gauges may be connected to it, being led immediately under the dead plate, which arrangement is found to be very compact and convenient. The best position for the scum pipe is at the side and not at the centre of the boiler, both on account of facility in fixing, and convenience in getting inside. A single pipe is sufficient.

The above description is not by any means given as if that were the only form of scum pipe that could be advantageously applied. It was designed for the use of the members as being adapted to stationary boilers, simple in construction, affording a large collecting area, and being free from any patent right. Upwards of a year's trial has proved it to be successful, and its more general adoption is consequently recommended. These pipes have already been made by the manufacturing engineers of Rochdale, Bolton, Bury, and other places, but are needed more generally, and a drawing at the office is open to inspection for the benefit of our members.

There are other plans in operation which, however, are subject to patent right. One of these consists of a series of vertical pipes, fixed in the centre of the boiler, each pipe having a trumpet mouth, to which a vertical telescopic movement is given, to allow for the changes of water level, the movement being effected by a copper ball float, so that the trumpet mouth rises and falls on the changes of water level, like a buoy on the rise and fall of the tide; the object being to keep the mouth of the pipe immediately below the surface of the water, in close proximity to the scum. A second plan consists of a trumpet mouth laid horizontally. Both of these arrangements are reported to give satisfaction, and, whenever opportunity offers, the results of their working will be noted, and particulars of the plan found to be most successful communicated to the members.

Some descriptions of incrustation, however, cannot entirely be removed by any blowing-out apparatus alone, however perfect; in such cases a little carbonate of soda may be added, which many of our members have applied with considerable success. Of the use of this, their experience is decidedly in favour, while the testimony with regard to complicated "boiler compositions" generally is that they found them expensive, in many cases useless, in others injurious, and have, in the majority of instances, discontinued them altogether. For fuller chemical particulars refer to Dr. Angus Smith's report to the Executive Committee upon the incrustation in boilers. The use of soda, without a scum pipe, is found in some cases to induce priming; the soda combining with the grease within the boiler, and producing foaming of the water.

The general adoption of scum pipes is, therefore, confidently recommended to the members, not only for the prevention of incrustation, but also, in order to lengthen the lives of their boilers, as well as to assist the engines in many cases, by preventing priming.

The most radical cure for the prevention of incrustation, though one involving considerably more outlay, at the first, than the above, will be found in the adoption of dry or "surface condensation," by means of which the boiler is fed with distilled water, the same being used again and again, with the exception of the slight amount lost through leakage. To those who are paying large amounts annually for a supply of town's water, and where the steam is consumed for engine purposes, the adoption of surface condensers is well worthy of serious consideration, not only on account of the saving in the water rates, but also in that of fuel, since non-condensing engines may, by this means, be converted into condensing, which is not at present generally the case where town's water is used.

L. E. Fletcher, *Chief Engineer.*

TYZARD'S IMPROVEMENTS IN THE CONSTRUCTION OF VESSELS, FORTS, &c.

In our last number but one we gave an illustrated description of a new plan for constructing vessels, forts, &c., but we omitted to state that the invention had been patented by Mr. W. L. Tyzard, engineer, of Mark-lane, who has been long known as a successful contributor to both mechanical inventions and scientific literature.

TO CORRESPONDENTS.

WATER-CASED SHIPS.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

Sir,—The power of water to resist a sudden impact is shown by the glancing of a cannon-ball when it strikes the sea, &c.

It occurs to me that if the sides of an iron vessel were made double, and the hollow cellular space between could be filled with water when going into action, a great amount of protection might be gained, even if actual impregnability were not secured. It is evident that one great advantage of this would be that the vessel at all other times might be light-weighted, and shells and liquid fire would be rendered less dangerous when exploding in water.

Rob Roy.

PROPULSION OF VESSELS.

Sir,—In reply to the observations and inquiry of "X. Y. Z.," in the last number of the Mechanics' Magazine, I may state that I have exhibited in action, at the Crystal Palace, models of various sizes, some of them being 4 ft. 6 in. in length, carrying 10 or 12 lbs. of cargo, and propelled at the rate of three miles an hour by a very fine jet of superheated steam, not exceeding 1-100th of an inch in diameter, in fact a mere point. Within the last few days another model of about the same size, with a little more steam, has gone between four-and-a-half and five miles an hour through still water. These results were of course obtained by boats of the shape best suited for the purpose.

With the marine engine, it is well known that increased speed may be obtained by simply increasing the length of the vessel, keeping the power in the same proportion as before. Now that my small boats go with a speed never before obtained from the same quantity of steam, a mere inspection of of the models will prove, and it, therefore, seems necessarily to follow that large vessels on the same plan will *at least* give an equally good result as from machinery. But the plan will be commercially useful if the result on a large scale should even be less. The enormous saving of space, impossibility of derangement, no outlay for costly machinery, no interference with the sailing qualities of the vessel, combined with the advantage of being able to steer her even in a heavy sea, with or without the rudder, will surely be an ample compensation for some diminution of speed, which really means nothing more than a slight increase of fuel.

I am, Sir, &c.,
Jas. Parker.

Claremont Cottage, Lilford-road, Camberwell.

Sir,—Seeing an article in your number of Oct. 31st, by "X.Y.Z.," on Mr. Parker's plan of propelling vessels, I would suggest to him the possibility of something like Giffard's Injector, being a power that will come into use as a propeller of vessels at a cheap rate; the great power that is exerted in feeding boilers, has surely some analogy to the propulsion of a body through water. If a jet of steam ¼-inch diameter can propel about 800 gallons of water per hour against 65 pounds pressure in boiler, surely a vessel where water is so easily got at would be more powerfully propelled by a jet of steam and water, than by a jet of steam and air, as in Mr. Parker's arrangement. If this will induce "X.Y.Z." or any other of your readers to think on the subject, my end will be gained. Yours respectfully,

Edinburgh, 4th Nov., 1862. A. J.

ARMOUR PLATES AND WOOD BACKING.

Sir,—As your correspondent "Civilian" invites discussion on opinions he has advanced, in reference to the impact of shot upon armour plates for vessels, I am induced to controvert one that forms an exception to the many excellent ideas contained in his papers, and one that has been impressed upon us so often as to look a little like a crochet. I allude to the alleged comparative worthlessness of wood as a backing to the armour. "The wood," he says, "offers no resistance worth speaking of to the crushing and penetrating effects" of shot. Now if he will limit his meaning here to what he subsequently says, that "in this arrangement there is nothing at the back of the armour plate *to aid it* in repelling the blow," I have little to object, for in respect to direct aid, nothing less than iron plate backing, or granite backing (as tried in some of the experiments); that is to say, nothing less than materials affording an intensity of local resistance, nearly equal to that of the armour itself, can offer much impediment to the bulging of the iron. A shot with the adequate velocity and mass to burst through it, against the slighter resistance of wood, the range of such resistance being only through so small a space as the depth of the bulge, will certainly do so with almost as much ease as though it were emerging into open space. But to advocate a backing of iron, in order to afford this "aid," is merely to say, that if to 4½ inch iron we add another inch or two of metal, whether separate or incorporate, we should be enabled to repel shot more efficiently than before. And to assert the fact that wood does not afford this kind of "aid," except in the slightest degree, is by no means the same as saying, nor does it follow as a consequence, that "wood offers no resistance worth speaking of," in the sense of total destruction to the passage of shot, whilst traversing the comparitive great distance of 18 ins. For the result of calculation is, that about 60 ins. of wood is sufficient to absorb the entire force of a 68lb. shot, moving with a velocity of 1,600 ft. per second. It would, however, I confess, be very desirable to ascertain whether the same result would be given by a direct experiment. I suppose they have put this point to the proof at Shoeburyness, and I suppose they know, or at least they ought to know, what are equivalents of thickness in wood and iron for equal resistances, from 2 in. plates up to the thickest yet penetrated, as determined by experiments for each case. For though calculation from one datum may be depended on pretty confidently in the case of wood, because the law of the resistance is known (unless indeed assumptions have had too much to do with it), yet in the case of iron, I suspect from the nature of the material that no law is known, and that in fact no law can be determined for the thorough penetration of plates, the results being likely to be very irregular. The measurement of indents upon immense solid blocks of iron might afford a formula not different perhaps from the ordinary one, but then it would be useless, for it is not probable that we shall ever prevent the thorough penetration of single plates, such as vessels will be able to carry. Only experiments for every case can be our trustworthy guide; mathematical science here, as upon almost all practical points, is a mere will-o'-the-wisp. However, the calculation I have given, although founded only upon a single Woolwich Academy experiment, is roughly sufficient for my purpose to convince "Civilian" of the great value of wood backing for the sake of its own resistance against a more than

half-spent shot, notwithstanding it may not at all "aid the armour-plate in repelling the blow." It is useful also in a very important manner to absorb the fragments of shot and plate.

Your correspondent appears to think also that a wood backing even facilitates the penetration of the plates. He says—"If the proposition were to prevent a 1-inch punch penetrating a ½-inch plate, would any man in his senses place it upon a wooden plank? Certainly not; for if he did, the machine would drive the punch through the iron." This remark does not display a practical knowledge of the manipulation of metals. A firm circumscribed support around the spot where a hole is to be punched, is precisely the means, as every blacksmith knows, to facilitate the operation; whilst a general elastic bearing, like that given by a "wooden plank," is the very means tending to defeat it. The fashioning of artistic forms in *repousse* worked upon thin sheet silver, would be endangered by the making of holes, if the artist had not a yielding resistance to punch against, produced by an appropriate backing to his work; wood, indeed, in this instance, would be too elastic, too efficient; there would be a general instead of a local depression. Your correspondent goes on to observe—"But if an additional thickness of iron were placed under the plate, or across the orifice of the die, the punch would not penetrate the plate." This is simply a truism, for it must needs be that a thicker metal, or what is equivalent to it, will be more repellant of punch or shot than one that is thinner. It is undoubtedly true, when a case is stated without limits or conditions, that iron for resistence is better than wood; and indeed for the matter of that, the opposite proposition is true also, that wood is better than iron. The question logically and usefully at insue is, what for *given* thicknesses are the comparitive values of iron and wood in the matter of resistance? And because wood is next to being worthless in the one particular, which is beside the question, of not preventing the plate-iron from bulging, "Civilian" concludes too largely, and even within the question, that it is almost wholly useless for resistance. This is jumping with a deduction into another fold, and if he is now inclined to put in a demurrer, I can only say I am unable then to perceive the pertinency of his reiterated denunciations, general and without making exceptions of wood for a backing; and that I should be puzzled to assign a meaning to such expressions as these, that "the iron plate has to do all the work," and that the "wood is only a medium for transmitting the blow to the ½-inch skin plate, and the ½-in. angle irons." The assumption is, that the plates are as thick as the ship can carry compatible with the uses for which she is intended, in which case it is as idle as it is truthful to propound, that thicker iron, whether in plates or in backing, would make her less vulnerable.

But there is a second question, which is more comprehensive, and that is, whether with a given weight of resisting materials (for there is a limited quantity which we are not permited to exceed), wood or iron is the most efficient in repelling shot? For though your correspondent should concede to me that a wood backing does indeed afford great resistance, he would still be entitled to argue that the weight of this wood given to an additional thickness, either of the armour plates or of the skin of the ship, would act more efficiently. For the present, I will allow that it would do so, but in this view of the subject there is omited the consideration that the resistance got from the wood backing is, in part, a resistance gained—an extra resistance, which does not altogether implicate a burden upon the buoyancy of the ship, inasmuch as the greater displacement produced is equal to nearly one half the increase of weight. As to the remaining portion of the backing, and turning the discussion now upon the merits of the question, I do not know what its resisting power is, in comparison with an equal weight of iron, though, as I have already said, they ought to know at Shoeburyness. But to make an approach to some conception thereof, let 6 in. thickness of iron be as much as a 68-lb. shot, with a velocity of 1600 ft. per second, can only just pierce; this result compared with the penetration in wood which I have already calculated at 60 ins., will give the equivalent depths for equal resistances of 1 and 10. Now the thicknesses of iron and wooden defences for equal weights, are about 1 and 6, so that the ratio of 10 to 9 is not great against oak wood, and in the case of teak wood, which is lighter, and judging from its resistance to crushing, is at least equally capable of resisting penetration, the ratio would be 11 to 10 in its favour. I do not rely, as you, sir, know very well, with too great confidence upon mathematical calculations, but the information they give me is all that I can get at present, and I think they may be trusted to the extent of teak wood being equal to iron, weight for weight. Even if it were not so, the many utilities belonging to wood, would countervail any difference that is likely to exist, and therefore I am of opinion, in opposition to "Civilian," Mr. Fairbairn, Mr. Scott Russell, and others, that provided we have armour sufficiently thick to keep out shells, all the rest of the defence should be of wood. And as to Mr. Whitworth's flat-headed shells, I think they are likely to fail with impact at any angle at which round shot will fail; but with this difference, that whilst a ball would simply glance, an elongated shell would also throw a somersault. I conclude with the remark that, if "Civilian" wants experiments to be made, as he says, "with different kinds of backing, calculated to prevent projectile punches being driven through armour plates," he must seek for something lighter than water, otherwise the ship cannot be supposed to be armoured so heavily as she ought to be; and if under this peremptory condition of lightness it is possible to find anything better than wood, I wish he may get it.

Yours, &c.,

Oct 27. BENJ. CHEVERTON.

Meetings for the Week.

MONDAY.—ROYAL GEOGRAPHICAL SOCIETY.—Sir R. Murchinson, in the chair. Latest explorations in Australia, by Landsborough, Walker, McKinlay, Howitt, &c., at 8.30 p.m.

TUESDAY.—INSTITUTION CIVIL ENGINEERS.—On the railway system of Germany, by R. Crawford, Esq., A.I.C.E., at 8 p.m.

THURSDAY.—CIVIL AND MECHANICAL ENGINEERS' SOCIETY.—On steam, by F. Campin, Esq., E.C., president, at 7.30 p.m.

Gossip.

TRIAL OF THE APOLLO.—On Thursday last week the new paddle-steamer "Apollo," built and engined by Messrs. Caird and Co., of Greenock, for the Bristol and Cork trade, proceeded down the Clyde on an official trial trip, the directors, engineer, and other officials of the company being on board. The average speed per hour attained, as tested by running the lights, was 14 knots, and as this speed was got in unusually rough weather, all on board were highly gratified with the result. The following are some of the principal dimensions of the new vessel:—Length, 220 ft.; beam, 26 ft.; depth, moulded, 14½ ft.; draft of water, 10 ft.; 735 tons O. B. M. The vessel is made to load, if necessary, on the ground without injury, and to shift without ballast. The hurricane deck amidships is 60 ft. in length, under which good cover is obtained for carrying horses. The full poop, of 65 ft. in length, is 7½ ft. from deck to deck in height, and the saloon is handsomely fitted for the accommodation of 65 passengers. The 'tween decks are very roomy and airy, and are fitted for carrying cattle, walking stages being provided at each hatch to enable stock to pass up and down conveniently. The engines are on the oscillating principle; cylinders 60 in. in diameter, stroke 66 in. in length. The three tubular boilers, carrying a pressure of 20 lbs. on the square inch, are made with dry bottoms. The "Apollo" left Greenock for Bristol a few days since, and on her voyage encountered very stormy weather, which well tested her sea-going qualities. The weather, however, moderated on reaching Kingston, and the run from that port to the Severn was made easily in 14 hours. She will be placed at once on her station between Cork and Bristol.

In the *Melbourne Argus* we find the following allusion to the mineral wealth of Australia:—"During the recess we despatched a special reporter to the gold-fields, to examine and report upon their state, as well as the condition of the miners, and the position and prospects of mining generally. Eleven of his letters have appeared in the *Argus*, and, so far as they have gone, they are entirely reassuring, showing that, even on our oldest gold-fields, mining is only at its commencement. The alluvial fields are still unexhausted, and auriferous quartz-reefs, without number, lie untouched in every district, for want of capital and labour. Attention has been drawn to our mines of antimony, silver, and iron, of which little or nothing was popularly known previously. The effect of these letters has already been to assist in restoring confidence in the resources of the colony, and to stimulate enterprise in new mining directions."

A prospectus has been issued of the Aerated Bread Company, to supply London with bread manufactured under the patents of Dr. Dauglish. The proposed capital is £500,000, of which £100,000 is to be first issued in shares of £10 each. The new method, by substituting machinery for hand labour, insures cleanliness, expedition, and certainty.

The Association of Foremen Engineers held the first of their winter series of meetings on Saturday, the 1st inst., at their rooms, 35, St. Swithin's-lane, City. Steadily increasing in numerical strength and in financial resources, this comparatively young society has fairly established itself among the literary institutions of the metropolis. During the meeting on Saturday, it was resolved unanimously to present a testimonial to Mr. Joseph Newton, H. M. Mint, honorary president of the Association for the last three years, for the zeal with which he has laboured in behalf of its interests. The next meeting is appointed to take place on the first Saturday in December, when a paper on the "Machinery in the International Exhibition" is promised. There is no doubt whatever that to the foremen of the various engineering establishments of the United Kingdom, as well as the heads of firms, the public are much indebted for the glorious mechanical display lately visible at South Kensington, and the remarks of a member of the former class thereon will be found, we should think, instructive.

INSTITUTION OF CIVIL ENGINEERS.—The Council of the Institution of Civil Engineers have awarded the following premiums:—1, A. Telford Medal, the Manby premium, in books, and a Stephenson Prize of 25 guineas, to Charles Augustus Hartley, M. Inst. C.E., for his "Description of the Delta, and of the Works recently executed at the Sulina Mouth of the Danube."—2, A. Telford Medal and a Miller Prize of 15 guineas, to John Henry Muller, of the Hague, for his paper "On Reclaiming Land from Seas and Estuaries."—3, A Telford Medal, and a Miller Prize of 15 guineas, to John Paton, M. Inst. C.E., for his paper "On the Sea Dykes of Schleswig and Holstein, and on Reclaiming Land from the Sea."—4, A Telford Medal, to James Abernethy, M. Inst. C.E., for his "Description and Illustrations of the Works at the Ports of Swansea, Silloth, and Blyth."—5, A Telford Medal, to John Bailey Denton, M. Inst. C.E., for his paper "On the Discharge from Underdrainage, and its Effect on the Arterial Channels and Outfalls of the Country."—6, A Watt Medal, to Joseph D'Aguilar Samuda, M. Inst. C.E., for his paper "On the Form and Materials for Iron-plated Ships, and the Points Requiring Attention in their Construction."—7, A Council premium of books, to James Brunlees, M. Inst. C.E., for his paper on "Railway Accidents, their Causes and Means of Prevention."—8, A Council premium of books, to Captain Douglas Galton, R.E., F.R.S., Assoc. Inst. C.E., for his paper on "Railway Accidents, showing the Bearing which existing Legislation has upon them."—9, A Council premium of books, to Henry Charles Forde, M. Inst. C.E., for his paper on "The Malta and Alexandria Submarine Cable."—10, A Council premium of books, to Charles William Siemens, F.R.S., M. Inst. C.E., for his paper "On the Electrical Tests employed during the Construction of the Malta and Alexandria Telegraph, and on Insulating and Protecting Submarine Cables."—11, A Council premium of books, to James Atkinson Longridge, M. Inst. C.E., for his paper on "The Hooghly and the Mutla."—12, A Council premium of books, to James Oldham, M. Inst. C.E., for his paper "On Reclaiming Land from Seas and Estuaries."

We learn, says the *Manchester Guardian*, on the authority of a gentleman of the highest respectability, that a wonderful discovery has recently been made in electricity as applicable to the purposes of the electric telegraph. Incredible as it may seem to many of our readers, it is said that experiments have established the fact that intelligible signals can be exchanged between distant stations without the intervention of any artificial conductor whatsoever, and that with equal success, whether the intervening space be wholly or partially land or water. The *modus operandi* has not been disclosed to us, and we are unable to say to what various services this invention may yet be applied. But the promoters of the new system believe it to be a reasonable expectation that this discovery may render unnecessary any future attempt to lay an Atlantic cable. We remember that, many years ago, this achievement was regarded by some scientific men as a speculative possiblity.

It appears from a blue book just issued that the select committee appointed to inquire into the expenditure incurred since the begining of 1858, on the various kinds of improved ordnance, whether obtained by contract or manufactured in the public

departments, and results obtained by such expenditure, have agreed to the following report:—"Your committee, having investigated the subject, referred to their examination, have taken certain evidence, which, on account of the advanced period of the session, they have agreed to report to the House; and they recommend that a committee on the same subject should be appointed in the next session of Parliament."

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

The Abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following Table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved, and combined with all the advantages of a division into classes. It should be understood that these abridgements are prepared exclusively for this Magazine from official copies supplied by the Government, and are therefore the property of the Proprietors of this Magazine. Other Papers are hereby warned not to produce them without an acknowledgement:—

Steam Engines, &c., 1008, 1016, 1041, 1046, 1056, 1059, 1061, 1063.
Boilers and Furnaces, 1012.
Roads and Vehicles, including railway plant and carriages, saddlery and harness, &c., 1020, 1025.
Ships and Boats, including their fittings, 1027, 1035.
Cultivation of the Soil, including agricultural implements and machines, 1000, 1052.
Food and Beverages, including apparatus for preparing food for men and animals, 1099, 1018, 1028.
Fibrous Fabrics, including machinery for treating fibres, pulp, paper, &c., 1002, 1003, 1006, 1007, 1010, 1011, 1022, 1031, 1047, 1048, 1053, 1055, 1064.
Buildings and Building Materials, 1014, 1038.
Lighting, Heating, and Ventilating, 1021, 1023, 1043.
Furniture and Apparel, including household utensils, time-keepers, jewellery, musical instruments, &c., 1024, 1036, 1037, 1039, 1044, 1045, 1049, 1054, 1057.
Metals, including apparatus for their manufacture, 1005, 1029, 1034, 1040, 1062.
Chemistry and Photography, 1030, 1042.

1000. B. Sharpe. *Improvements in harrows and rakes.* Dated April 8, 1862.

In constructing a harrow suitable for harrowing grass lands, for distributing manure thereon, and also for harrowing other land, a bar, with wheels at the ends, is used in front of the implements, and to this bar shafts or suitable means for attaching a horse are applied. Behind the bar three frames of teeth are applied, they being connected to the bar by suitable links. These frames of teeth are each made in two halves, hinged to each other, and to a plate or frame having as many holes as there are teeth in the frame, so that by lifting either of the two sections of which a harrow is formed, the teeth are forced up through the holes of the plate or frame which retains its position, by which means the several teeth will be caused to deposit any accumulation which they may have gathered. Behind these harrows there are three or other number of parallel bars, at a distance apart, connected to each other at the chains by chains, and behind each bar is a chain, the ends of which are fastened to the ends of the bars, the chains being somewhat longer than the bars, so that whilst the bars retain their straight positions, the chains assume curved lines as they are drawn over the land. In order that the teeth of the horse-rakes may from time to time be caused to deposit the accumulation of materials raked up by them, a cam, or projection, is applied on one of the wheels, which, in its rotation, acts on a lever which carries the teeth to be lifted and held off the land until they have deposited their accumulation on to the land. In some cases a horse-rake is made with four sets of teeth, the arms of which are connected with the bar or axle of the wheels, such arms radiating from such bar or axle; and the teeth of each set may be so arranged as to be turned back on hinges or axes, so as for a time to be out of action, whilst other sets of the teeth are in action; or all the sets of teeth may be in action at one time. In using a horse-rake thus constructed, the sets of teeth which, for the time, are not turned out of action, come into work in succession, and they are released and allowed to go out of action by projections on the wheels or otherwise, so that when one set of teeth have, for a time, accumulated hay or other matters on the land, that set of teeth will be released, and will go out of action whilst the next set of teeth will come into position below the bar or axis, and will be retained until, by the rotation of the wheel, this set becomes free to go out of action in a similar manner to the first-mentioned set. *Patent completed.*

1001. H. A. Holden and C. Weekes. *Improvements in apparatus used in drawing water or other fluids from cisterns, tanks, and other vessels.* Dated April 8, 1862.

For this purpose the outlet pipe enters the bottom of the cistern or vessel, and to the end of this pipe is connected a flexible pipe; this pipe is of such a length that its mouth, or open end, can be raised above the level of the water or fluid in the cistern or vessel, so that no water can pass away through the outlet pipe, but when the mouth or open end of the flexible pipe is depressed below the water level, the water can flow freely through the outlet pipe. In order to raise and lower the mouth of the flexible pipe, the inventors prefer to connect it to one arm of a lever, the other arm of which lever projects beyond the edge of the cistern or vessel, so that by acting on this arm the mouth of the flexible pipe may be raised or lowered. *Patent abandoned.*

1002. E. B. Sampson. *Improvements in apparatus for supplying oil or other liquid to wool as the same is fed into carding engines.* Dated April 8, 1862.

For the purposes of this invention a trough or vessel is placed below the lower feed roller of a carding engine, such trough or vessel being somewhat longer than the feed rollers. Into this trough or vessel the oil or other fluid is placed, and such oil or other fluid is kept constantly supplied to the under surface of such lower roller by its dipping into and being partly immersed in the oil or liquid in the trough or vessel; or in place thereof there is a roller or endless band partly immersed in the trough or vessel, the upper surface of which is in contact with the under surface of the lower feed roller. By either of these arrangements the surface of the feed roller will have oil or other fluid uniformly spread over all parts of its surface with which, for the time, the wool is in contact. The wool is supplied to the feed rollers by an endless apron as heretofore, in such manner, however, as to feed the wool nearly up to the nip of the feeding rollers, and as the wool passes off the feed apron it comes in contact with that portion of the under feed roller upon which oil or fluid has been spread, as above explained. *Patent abandoned.*

1003. J. Lawson. *Improvements in balling cotton and thread.* (A communication.) Dated April 8, 1862.

This invention is not described apart from the drawings. *Patent completed.*

1004. J. Wright. *Improvements in joining together armour and other thick metal plates, beams, and girders.* Dated April 8, 1862.

In carrying out this invention the patentee slots, planes, or in any convenient way makes one or more dovetails in the materials to be operated upon, the oblique sides of which are also oblique to the surface, that is to say, the two opposite sides of each dovetail are to be oblique to the end or side, and also oblique to the two surfaces of the plate, girder, or beam. This obliquity of the sides of the dovetails to the surfaces is a little more in one plate or half beam or half girder than in the other, so as to permit of a taper key to be forced or driven in between those two pairs of oblique sides of the dovetail, and thus by means of these keys draw and bind the plates or component parts of the beam or girder together. In beams the obliquity might be dispensed with, and rivets or screws used to form the dovetail. *Patent completed.*

1005. T. Cobley and J. Wright. *Improvements in the method of, and the apparatus for, heating auriferous and argentiferous minerals and ores, for the purpose of extracting and separating the gold and silver from the other metals, minerals, and substances combined therewith. Also in the method of treating the various residues resulting therefrom, and in the utilization, application, and use of the said residues when so treated.* Dated April 8, 1862.

We cannot here give space to the details of this invention. *Patent completed.*

1006. S. Rodgett. *Certain improvements in power looms for weaving.* Dated April 9, 1862.

This invention is designed for the purpose of dispensing with the weights hitherto employed to weigh the yarn beam at the back of the loom, and consists in the novel application of a screw and nut, or screws and nuts, to the friction rope coiled round the yarn beam. One end of the rope is furnished with a screw, and the rope is coiled round the "beam" as usual, and thence passes under a pulley guiding it to the rocking or slay shaft, to which it is attached by means of a nut, in such a manner as to be adjustible, so that, as the slay vibrates, the tension of the yarn is varied; when shedding it becomes slightly slackened, and tightened when "beating up." *Patent abandoned.*

1007. J. E. H. Andrew. *Improvements in looms for weaving.* Dated April 9, 1862.

This invention consists, 1, in applying to the improved horizontal picking motion a metal picking sword, instead of the ordinary picking stick, to which is forged or otherwise connected a socket containing a picker of leather, or other suitable substance; and the said picking sword may be cranked to work in the drop-box of a loom. 2, In improvements connected with leading or pattern chains for regulating the movements of the drop box, and giving a sliding movement to, or reversing the motion, of the pattern, cyclinder, or barrel, or parts thereof, or for other requirements in fancy weaving. *Patent completed.*

1008. S. Farrow. *Improvements in machinery or apparatus for regulating the supply of steam from the boiler to the cylinder or pipes of steam engines, which improvements are also applicable to gases or fluids.* Dated April 9, 1862.

This invention consists in the employment of a small cylinder closed at the bottom, and having in its interior a piston exposed at the top to the pressure of the atmosphere, and also to the action of the lever and weight. The steam, gas, or fluid is admitted to the small cylinder through two internal apertures, and passes into the interior of the piston through two corresponding apertures, and from thence through a larger aperture to the exit pipe of the small cylinder leading to the steam engine cylinder pipes or other requirement. At the front of the larger aperture of the piston there is a thoroughfare leading to the underside of the piston, so that the steam, gas, or fluid may raise it according to their pressure, and the resistance of the lever and weight, so that when the apertures of the small cylinder are fully open to the apertures of the piston, the supply of steam, gas, or fluid is at its maximum, but as the piston rises from its under pressure, the apertures of supply are being closed exactly in proportion to the weight upon it, and thereby regulate the supply in a self-acting manner. *Patent completed.*

1009. G. Hollinshed. *Improvements in sandwich cases and similar articles.* Dated April 9, 1862.

This sandwich box or case is composed of two main divisions, distinct from each other, namely, the receptacle and the cover. The receptacle is formed of four sides hinged to the bottom or rim in such manner that they can be raised to a vertical position, and from the box or case when it is required for use, and folded downwards upon the bottom, then placed within the rim of the cover, so as to occupy but little space when the box or case is not required for use. The sides are provided with hooks and eyes, or other fastenings, for the purpose of holding them together when they are placed in a vertical position. *Patent completed.*

1010. J. Bullough and J. Bullough. *Improvements in looms for weaving.* Dated April 9, 1862.

In carrying out this invention, instead of the usual mode of causing the crank which gives the lay its to and fro motion to be driven at one uniform speed, the patentees give it less speed during one part of its revolution than the other part, for the purpose of allowing the shuttle time to pass along the race, and thereby enable the loom to be worked at an increased speed. They attain this object by means of eccentric toothed wheels and chain, by intermittent surfaces, and also by eccentric surfaces in combination with weights or springs. Another part of the invention consists in an improved arrangement for stopping the loom when the weft thread breaks or is absent, and also for causing the shuttle to stop at the setting on side and arresting the lay at or about the best position. *Patent completed.*

1011. W. Taylor. *Certain improvements in machinery or apparatus for preparing and spinning cotton or other fibrous materials.* Dated April 9, 1862.

This relates, 1, to a simple and effective arrangement of apparatus in the drawing frame for preventing the passage of drawing from the rollers to the coiler motion, or undue waste of material through rollers lapping, by the instant stoppage of such machine if the sliver becomes broken, or when a snarl or lump is formed that cannot pass through the cone trumpet or guide. The second part consists in an arrangement of apparatus for the stoppage of the drawing frame, or any given or desired weight or length of drawing being deposited in the cans, so as to prevent waste and damage to the drawings through the cans becoming overloaded. The third part consists in an arrangement of apparatus for preventing single slubbings or rovings from passing on to the bobbin, and where an end breaks, through roving, lapping, or other cause, the machine or frame is instantly stopped. The fourth part consists in an arrangement of apparatus to be applied to warping and winding frames, and bobbin or cop reels, so that, if any one end or thread breaks, the frame or machine is instantly stopped. *Patent completed.*

1012. W. Davis. *Improvements in puddling, balling, and re-heating furnaces.* Dated April 9, 1862.

Here, in place of using a horizontal grating of fire bars, the bars of which are laid in a direction from front to back of the fire-place, inclined gratings of fire bars are used, one half of the grating of a furnace inclining from one side to the middle, and the other half inclining from the other side, so that the lowest point is in or about the middle of the fire-place, and the fire bars are, as heretofore, laid in a direction from front to back of the fire-place. *Patent completed.*

1013. J. Jones. *Improvements in constructing and arming ships and vessels.* Dated April 9, 1862.

In order that the power of steam may be employed when along side of an enemy's ship to make a hole therein below the water, provision is made in constructing a ship or vessel, and in applying steam machinery thereto, for employing what may be termed a steam battering-ram, adapted to produce the effect above mentioned. For this purpose, at the bow or other part or parts of a ship or vessel (suitably constructed to resist projectiles, and to be propelled with as much speed as may be) a ram or rams is or are applied. Each ram consists of a shaft or bar capable of sliding water-tight to and fro through the bow or other part of the ship or vessel. The inner end of this bar or shaft is in connection with the piston of a steam cylinder, so as to be worked by steam quickly to and fro in a suitable manner to a steam hammer. *Patent completed.*

1014. J. Langston. *Improvements in the manufacture of Portland cement.* Dated April 9, 1862.

Here the patentee employs, in grinding the materials, only so much water as will make a dough or paste, suitable for being at once dried without the separation of water by settling. The drying apparatus he employs consists of ovens heated by furnaces or fire bars below, and the flues from these furnaces pass over the top of the ovens in the vaulting of the roof. Ovens so arranged will dry the materials more rapidly than the open floors, and with smaller expenditure of fuel. The passing the materials from the grinding apparatus to the drying ovens without the use of the settling ponds renders it necessary that no lumps should be allowed to escape the grinding apparatus; hence he employs, to effect or to complete the grinding rollers, set at a short distance the one from the other, and between which the materials are caused to pass; or a roller revolving at a short distance from a stationary surface may be employed. *Patent completed.*

1016. J. Knowelden. *Improvements in steam, water, and other fluid engines.* Dated April 9, 1862.

The patentee constructs the frame, and fixes the cylinders of engines worked by steam, water, or other fluids, as follows:—For condensing engines, he forms the frame hollow, so as to form the condenser, and, if convenient, round. He fixes to this frame one or more cylinders, but in all cases he prefers an uneven number. He makes a division, so as to form it into two separate chambers, into one of which the water to supply the boiler is admitted, which, meeting the first discharge of the steam from the exhaust pipe, causes partial condensation thereof, while, at the same, the water becomes heated; that portion of the steam remaining uncondensed passes into the second chamber, when, again meeting with a further supply of cold water, the condensation is completed. For agricultural and other portable engines, he construest the casing of the boiler of sufficient length to form the frame, in which he fixes any number of

cylinders, but of these, by preference, three. In locomotive and traction engine he fixes the cylinders to a round framework, which may be connected to, or which may form the wheels. He makes the crank shaft of the engine hollow, to form the steam and exhaust pipes, and he fixes the crankshaft to the springs or frame of the boiler or carriage; or the cylinders may remain stationary. Secondly, he constructs cylinders and pistons as follows:—If for open cylinders or trunk engines the piston is bored to form the joint of the connecting rod, and is fitted with a cap or gland, and bored spherical, so as to allow the piston free action. He also constructs the cylinder covers and bottoms with a chamber, between which and the cylinder he fixes a diaphragm of any suitable material, and a frame or grating to prevent the same being forced in the cylinder. He establishes a connection between the chamber and the supply pipe, to equalise the pressure in the cylinder, thus leaving the diaphragm at liberty to move by priming or other causes. In steam engines, where surface condensers are used, he forms the condensers of a series of flat chambers, through the centre of which passes a pipe, with small holes made in each chamber; the chambers are held together by bolts passing through collars, leaving sufficient space to allow the condensed water to return, the steam first passing through the casing of the engine, the lowest part of which is made to form a chamber to receive the first steam and injection water, so that it may be returned to the boiler hot. The water from the air pump is passed through a rotary refrigerator, which at the same time gives motion to the water acting on the condenser. *Patent completed.*

1017. W. E. NEWTON. *An improved apparatus for raising and forcing water and other liquids.* (A communication.) Dated April 9, 1862.

This consists, principally, of a steam or compressed air pipe, the mouth of which enters, and is surrounded by, a socket, in which is an opening for the admission of water or other liquid to be raised from the well, reservoir, or other source of supply, and from which a delivery pipe leads to the point where it is to be delivered, the direction of the steam or air pipe being the same as that of the contiguous portion of the delivery. The issuing steam or compressed air expels the water from the delivery pipe, and creates a vacuum behind it. The place of the water that is so expelled is supplied by water drawn up to fill the vacuum, or forced up into the socket from the well, reservoir, or other source by the pressure of the atmosphere. *Patent completed.*

1018. W. MAYS. *Improvements in machinery for grinding corn and other substances.* Dated April 9, 1862.

This relates, principally, to a novel arrangement of parts for connecting the drawing gear with the top stone of a mill, and consists in the employment of a spring griping arrangement. The cross-piece, instead of fitting loosely between the checks, is made to bear against two moveable blocks, which project through the checks, and are forced up against the cross-pieces by means of strong springs. In order to conduct air down the eye of the stone, inclined flanges or guides are adapted to the eye-block, so that as the runner rotates the air may be guided downwards in an oblique direction to the grinding surfaces below. *Patent abandoned.*

1019. R. THEYSON. *Improvements in cork-cutting machinery.* Dated April 9, 1862.

This consists in a machine which cuts corks by thin steel cylinders sharpened at one end, being made to pass perpendicularly through cork wood, which has previously been cut into strips as long as they can be got. The width or height of the strips will give the length of the corks, and their thickness will correspond with the diameter of the cylindrical knives, for each of which the strips suitable must be sorted. These strips are put into the machine, which is self-acting in all its parts. By this machine cylindrical corks of all lengths and thicknesses can be cut at the rate of from 30 to 60 per minute, according to the size of the corks to be cut. *Patent completed.*

1020. E. FUNNELL. *A self-acting indicator signal for railways.* Dated April 10, 1862.

This consists of a dial plate erected on the top of a pillar; the dial is divided into three parts, red, green, and white, and is divided to mark the time of ten minutes, and is also furnished with an indicator, which revolves backwards on the passage of a train, after which the hand returns and records the number of minutes since the trains passage, by which the driver of a succeeding train can regulate his speed accordingly. On the upper portion of the dial is fixed a lens, by which transparent colours are given for night signalling, by the aid of gas or lamp. After the passage of a train, red light shows for five minutes, which then disappears, and shows green light for five minutes, after which bright light remains until the passage of another train makes contact, by which the movements are again repeated. *Patent completed.*

1021. D. FRYER and W. J. WILLIAMS. *Improvements in the method of, and apparatus for, letting on and cutting off the supply of gas to groups or districts of streets and other lamps from a central point or depot.* Dated April 10, 1862.

This consists in applying to the ordinary branch gas tube which supplies each lamp a flexable air-tight junction of india rubber, or such like material; that is to say, the gas tube may be severed and joined with a piece of flexible tube having air tight joints; on each side of the tube may be placed two small plates to act as nippers, so that, if they be compressed by any force, they will nip the flexible tube and close the passage. The inventors now enclose the flexable portions in an air tight flexible chamber, formed of materials capable of allowing it to collapse and expand without fracture when the air is withdrawn or forced into it. With this arrangement it will be seen, that if the air by any means be extracted from the air-tight flexible chamber, it will collapse, and the external pressure will cause the nippers to grasp the flexible tubes, and thus close its passage and cut off the supply of any gas passing through to the lamps; and upon the equilibrium being restored by the admission of air, the current of gas will be shut on the nippers relaxing their grasp from this relaxed pressure. If, on the other hand, the air be forced into the chamber, the increased pressure will act in a similar manner. *Patent abandoned.*

1022. W. ARMITAGE. *Improvements in looms for weaving.* Dated April 10, 1862.

This relates to the taking up motion, and consists in improved modes of making it positive. From one end of the sword arms or other working part of the loom motion is given by a connecting rod to a double lever, having a series of catches above and below the centre of oscillation, which catches give continuous motion to a ratchet wheel communicating by bevel or spur gearing, or worms and worm wheels with the taking up beam. In one of the arms of the double lever there is a circular slot, in which a stud at that end of the connecting rod descends, for the purpose of gradually shortening the traverse of the catches as the cloth increases in diameter. This descent of the connecting rod is obtained by jointing it near the stud to one end of a second double lever, having at the opposite end a slot, in which is one of the ends of a rod or lever resting on the cloth. The extreme ends of the rod or bar slide in angular slots or grooves fixed to the framework of the loom, so that, as it rises with the cloth, it moves towards the interior and shortens the length of the second double lever on that side, so as to give a gradual increasing movement on the lever on the other side, and cause the connecting rod to descend in the slotted arm of the first double lever with a gradually increasing movement, so as to shorten the traverse of the catches and retard the revolution of the ratchet wheel exactly in proportion to the winding on of the cloth, and thereby produce an efficient positive taking up motion. *Patent abandoned.*

1023. W. NUNN. *Improvements in the construction of lanterns for ships and signals.* Dated April 10, 1862.

This consists in fixing the lenses on detached metal or other frames which can be attached to the lantern by screws, or made to slide into their required position in grooves formed in the frame of the lantern, and be fixed there by screws, springs, or bolts, or any other suitable means. These grooves may either be on the outside or inside of the frame of the lantern, and may be made to receive one or more lenses, according to the purpose for which the lantern is required. By these means a lens, when broken or injured, may be removed and replaced by a new one in a few minutes by an unskilled workman. *Patent completed.*

1024. J. HOUGHTON. *An improved haversack.* Dated April 10, 1862.

This consists in forming haversacks with two divisions or flaps with pockets therein, so that when suspended in the middle, the one flap may hang over and cover the other flap. *Patent completed.*

1025. A. BLACK. *Improvements in swing-bridges adapted for crossing lines of railways and other ways.* Dated April 10, 1862.

This consists in so constructing a bridge, that it shall be capable of being readily and easily moved or swung from its original transverse position, into a longitudinal position with the lines of rails or permanent ways, and thus allow railway trains to pass clear of the said bridge. This improved bridge is so constructed as to close or fold up into a very small compass. *Patent abandoned.*

1,026. J. LILLYWHITE and T. NIXON. *An improved bowling apparatus for cricket balls, to be called "the balista."* Dated April 10, 1862.

This bowling apparatus is constructed as follows:—On a foundation plate of iron, which is to be pegged or fastened to the ground behind the wicket, a standard is secured, on the top of which a horizontal bar is so arranged by a pivot (to which it is hinged) working in a socket in the standard as to allow of being turned horizontally thereon. One end of this bar is furnished with a cross piece, each end being bent upwards to form vertical arms, to which are attached the ends of a powerful vulcanized india-rubber strap or band; the other end of the bar is also bent up, and the centre of the band is pulled back thereto by a leather loop, and held by a catch, and the ball having previously been placed in the centre of the band, while being drawn back, will be firmly retained by the compression of the rubber. A trigger is arranged to work on a pin let into the bar, and is acted upon by coming into contact with a projection on the top of the standard. The apparatus is to be so placed that when charged by the ball, the ball shall be set at right angles to the line of the wickets; when the ballsman is ready, the bar is turned on its axis, and on arriving in a line with the wicket, the projection acts upon the trigger and catch and releases the india-rubber band, projecting the ball accordingly. Regulating screws, situated near the pivot, elevate or depress the bar, and the direction of the ball, and also regulates the discharge thereof by contact with the projection and trigger. *Patent abandoned.*

1027. C. P. COLES. *Improvements in masts for ships.* Dated April 10, 1862.

This invention consists in constructing masts of a central and two side tubes of iron or steel. The tubes pass through and are keyed to the decks, the central tube being carried in a direct line, while the two side tubes extend from the central tube at their bases, and are carried up at an incline till they unite with the central tube at or near the upper part. The central tube is continued upwards to form the topmast, or a separate tube is fitted thereto. The mast becomes, as it were, self-supporting, and shrouds and other supporting rigging are dispensed with. *Patent completed.*

1028. G. D. MERTENS. *Improvements in the preparation of materials to be employed in the making of beer, and in the machinery or apparatus employed therein.* (A communication.) Dated April 10, 1862.

This relates more particularly to an improved system or mode of treating worts with a view to the solidification of the same, whereby the preparation may be easily kept for any length of time in any climate, and be subsequently used, when required, for the manufacture of beer, by simply dissolving in water. According to this invention it is proposed to evaporate the worts in a closed vacuum pan, heated by steam heat, and having a suitable exhauster in connection therewith, for the purpose of facilitating and expediting the process of evaporation at a low temperature, so as to prevent any charring of the substance, and for the same object it is of the greatest importance that the substance under treatment be kept in a constant state of agitation. *Patent completed.*

1029. L. CHRISTOPH, W. HAWKSWORTH, and G. P. HARDING. *Improvements in drawing metals and in the machinery or apparatus employed therein.* Dated April 10, 1862.

This relates to a peculiar system or mode of drawing metals, whether of a tubular, hollow, or solid section, and consists in the application to that purpose of hydrostatic pressure, in lieu of the ordinary mechanical power heretofore adopted. In carrying out this invention, the patentees employ a hydrostatic cylinder and ram, the gripper bars being secured to the end of the ram, whilst the draw plates or "wordles" are fitted into a suitable support or flange cast on the cylinder. *Patent completed.*

1030. H. DEACON. *Improvements in the manufacture of caustic soda.* Dated April 10, 1862.

This consists in stopping the evaporation of the caustic liquors at an earlier stage than at present, removing the salts precipitated during evaporation as usual, and continuing the evaporation or concentration until the caustic alkaline liquor will deposit crystals of hydrated caustic soda on cooling to the ordinary atmospheric temperature. These crystals of hydrated caustic soda, after the mother liquors have been separated therefrom, are nearly pure, or sufficiently so for commercial purposes. It consists further in effecting the separation of the mother liquors from the crystals of the hydrate of soda. This the patentee prefers effecting by the application of a small amount of heat in any convenient vessel and way. *Patent completed.*

1031. J. PLATT, W. RICHARDSON, and W. HOLLAND. *Improvements in carding engines.* Dated April 10, 1162.

This invention is not described apart from the drawings. *Patent completed.*

1032. J. PETRIE, JUN. *Improvements in machinery or apparatus for blowing and exhausting air.* Dated April 10, 1862.

This invention is not described apart from the drawings. *Patent completed.*

1033. G. BURGE. *An improved means of protecting forts, ships, and other structures and places against projectiles and other striking bodies.* Dated April 10, 1862.

Here the patentee uses a moveable body, hereinafter called a shield, that is to say, a body capable of receding, retiring, or recoiling, or of moving backward or inward when struck with sufficient force, and which may also, if desirable, be so arranged that, after having been so moved, it shall be returned or restored to its previous position by balance weights or other contrivances; and he applies this shield to the ship, fort, or other structure or place (to be protected) in such wise that it shall present an outward face, front, or surface of iron or other metal and material, to resist or receive the blow of the projectile or striking body. The shield may, if desired, be constructed hollow, and be filled or loaded with iron or other material. Any required number of shields may be used. There are other modifications. *Patent completed.*

1034. C. BARTHOLOMEW and J. HEPTINSTALL. *Improvements in making circular blooms such as are used in the manufacture of tyres, and for other purposes.* Dated April 10, 1862.

In making a circular bloom of iron, after the iron is made and rolled into a puddled bar, it is then cut into segments or radial pieces; that is to say, the puddled bar is divided into pieces of equal and comparatively short lengths by cutting it across at an angle, the ends being made to slope alternately in either direction, and in such a manner that if the pieces be laid round in a circle, their longer sides outwards and shorter sides inwards, they will butt accurately end to end, and make up a complete polygonal wing. The mode in which the pile is made for the bloom from these segments, or radial pieces, is as follows:—A smaller bar of iron of sufficient length is coiled round a mandril, so as to produce a flat coil of sufficient width to form the top and bottom of the intended pile. Upon the bottom coil a circle of the pieces of flat bar above-mentioned is placed, and upon that circle another circle of pieces is built, so as to break joint with the pieces below, and then another circle of such pieces of iron is placed likewise breaking joint, until a sufficient thickness is obtained; upon the whole, a top coil, similar to the bottom coil, is placed, and the pile is, when completed, ready to be placed in the ball furnace, and when it has attained sufficient heat, it is then put in a die, of the requisite form for producing the bloom of the required outside shape, when it is struck by a steam or other hammer of the requisite power and weight to thoroughly weld the pile into the requisite form. *Patent completed.*

1035. O. REYNOLDS. *Improvements in building ships and other vessels.* Dated April 10, 1862.

For the purposes of this invention in constructing the lower parts of a ship or vessel, wedge-formed timber is used, the thinner edge of the wedge being inwards, and the thicker edge outwards; between each stroke of these wedge-formed timbers there are plates of iron or steel as wide as the wedges or filling pieces of timber. The wedges and the plates of iron both run in a direction fore and aft of the ship or vessel, and, by reason of the filling pieces of timber being wedge-shaped, the required curved form for the bottom of a ship or vessel is obtained. Through these wedge-formed timbers, and through the plates of iron or steel between them, screw-bolts are passed, and the whole strongly screwed together. The walls of a ship or vessel are similarly constructed. The plates of iron or steel between the horizontal layers of timber used in forming the sides of a ship or vessel, from some distance below the water-line upwards, are formed with thick massive outer edges, which overlap the filling pieces of wood, and form the outer surface of a ship, so that a ship may be capable of resisting shot and other projectiles, and also to make the body of the ship of great strength. The layers of wood, and the plates of iron or steel used in forming the sides of the ship, are perforated to receive upright screw-bolts to screw or compress the whole of the layers together at proper intervals. *Patent abandoned.*

1036. T. B. DAFT. *Improvements in coverings for the feet.* Dated April 10, 1862.

According to this, the inventor makes what he calls a vulcanised india-rubber mocassin from two flat pieces of short india-rubber compound, which are connected together at their edges, and then vulcanisod; the joining of the sheets is effected, by preferenbe, by cutting the two sheets together, so that the joint may not be thicker than any other portion of the article. In this manner a cap is made suitable for fitting over the front part of the sole and upper of a shoe or boot. The portion which passes over the top of the foot is of such a size as to completely protect the front of the upper of the shoe or boot from wet and dirt, and the portion which passes over the sole of the shoe or boot extends as far as the waist or centre portion thereof beyond the tread, and there it fits perfectly close, so as to prevent mud working in between the sole of the shoe or boot and the under surface of the mocassin. This perfect fit is ensured by making the open end or mouth of the cap smaller than the part of the foot which it is to fit, so that it may require stretching in putting it on; its elasticity allows it to stretch freely, and causes it also to clasp the foot closely. The mocassin is secured to the foot by means of strings or straps attached to it at the centre of the upper part or portion, and which the wearer of the article ties or buttons round the ankle. *Patent abandoned.*

1037. W. FOX. *Improvements in the manufacture of brooms and brushes.* Dated April 10, 1862.

For the purpose of this invention flat steel wire, or narrow strips of thin sheet steel, are used in a hardened and tempered state. These steel wires or steel strips are fixed together and to a suitable head or block. *Patent completed.*

1038. A. TRIMEN. *The protection and solidification of magnesian limestone and other stones, and for the prevention of the passage of water through the same.* Dated April 10, 1862.

This consists in issuing certain lacs in naptha or spirits, reducing the same to a fluid state, and filling the pores and coating the surface of the stone therewith. *Patent abandoned.*

1039. H. HOLLAND. *Improvements in manufacturing the stretcher points of umbrellas and parasols.* Dated April 11, 1862.

The patentee claims, first, in improvements in manufacturing the stretcher joints of tubular steel ribs for umbrellas and parasols, viz., constructing with each tubular rib a steel flange, which is hardened and tempered with the rib, and afterwards covered with brass; second, in manufacturing the stretcher joints of solid steel ribs for umbrellas and parasols, viz., compressing and flattening out from each steel wire intended for a rib flange, and afterwards hardening and tempering such steel wire rib length with such flange, and covering the flange with brass. *Patent completed.*

1040. J. T. GRICE. *Improvements in the manufacture of twisted metallic tubes.* Dated April 11, 1862.

The patentee claims filling the tube to be twisted with a yielding substance, either solid or in powder, or inserting in the tube to be twisted a small solid mandril of steel or other hard substance, for the purpose of preventing the irregular yielding of the tube during the twisting process. *Patent completed.*

1041. E. H. CARBUTT. *Improvements in pistons.* Dated April 11, 1862.

This relates to a peculiar construction of piston, suitable for all purposes where ordinary pistons are now used, and consists in making such pistons of corrugated cast steel, whereby considerable lightness, combined with strength, is obtained. *Patent abandoned.*

1042. J. GARNETT. *Improvements in apparatus for washing photographic pictures.* Dated April 11, 1862.

This consists in the use of a shallow box, perforated on its upper and under side, into which box the prints or pictures requiring to be rinsed or washed are deposited, suitable divisions being placed in the box to separate the different sizes of prints, which divisions or partitions are made moveable to suit different sizes. The box with the photographs therein is placed inside a convenient reservoir of water, and a vertical motion is imparted to the box whilst submerged by a handle or other suitable device, so as to cause the water to flush alternately through the top and bottom perforations in the box, and thereby effectually rinse the pictures on both sides. *Patent abandoned.*

1043. W. E. GEDGE. *An improved lamp for lighting mines.* (A communication.) Dated April 11, 1862.

This invention is not described apart from the drawings. *Patent completed.*

1044. J. F. MATHIAS. *An apparatus for pressing and ironing straw hats of any shape or form.* Dated April 11, 1862.

This invention is not described apart from the drawings. *Patent completed.*

1045. F. RIGOLLOT. *Improvements in machinery or apparatus for manufacturing riveting pegs for boots and shoes and other pins or pegs.* Dated April 11, 1862.

This invention is not described apart from the drawings. *Patent completed.*

1046. J. M. LAUDMAN. *Improvements in hydraulic engines.* Dated April 11, 1862.

This invention is not described apart from the drawings. *Patent abandoned.*

1047. T. KNOWLES, J. HOUGHTON, W. KNOWLES, and W. HOUGHTON. *Improvements in looms for weaving.* Dated April 11, 1862.

Here, to avoid reversing the loom, the inventors apply a catch box and apparatus or mechanism so arranged as to temporarily disconnect the lathe or going part of the loom from the different apparatus which gives motion to the shuttle boxes, and the jacquard engine, or the apparatus by which they are actuated, that they can be turned back simultaneously by hand whilst the going part of the loom remains stationary, by which they can readily put all the parts right, or in proper relative position again. *Patent abandoned.*

1048. E. BUTTERWORTH. *Improvements in machinery for applying adhesive substances to preserve the form of cops of yarn.* Dated April 11, 1862.

This is applicable to that class of machinery known as mules or twiners, and consists, 1, in traversing the box that carries the adhesive substance in front of the spindles by a band or other means, which is driven from some convenient part of the machine. 2, In stopping the box when it has got as far as required by self-acting apparatus. 3, In constructing the box so that, when required, the adhesive substance will not run out of it. 4, In making the paste box so that more or less of the adhesive substance can be let out as required. *Patent completed.*

1049. W. CLARK. *Improvements in the manufacture of leathern accoutrements.* (A communication.) Dated April 11, 1862.

This relates to the employment of metal fastenings for uniting leather, such as for military or civil accoutrements, in place of the threads of vegetable material hitherto used for sewing the different parts together. The fastenings employed may consist of screws or rivets of copper wire or other metal. *Patent completed.*

1051. J. H. JOHNSON. *Improvements in firearms.* (A communication.) Dated April 11, 1862.

This relates more particularly to that class of firearms in which the distance between the sights is considerably longer than the length of the barrel, and consists, firstly, in certain improvements in the existing arms of this description; and, secondly, in a novel construction and arrangement of the arms of the class referred to. We cannot here quote the details of the invention. *Patent completed.*

1052. J. HOWARD, E. T. BOUSFIELD, and T. PHILLIPS. *Improved apparatus applicable to steam cultivation.* Dated April 11, 1862.

The patentees claim, first, regulating the giving off of the slack rope of windlasses by friction gearing, in the manner described. Secondly, ensuring the automatic traverse of the anchor by the action of the taut or slack rope, in the manner described. Lastly, mounting the pulley or roller of rope porter on a rocking bar or its equivalent, for the purposes described and set forth. *Patent completed.*

1053. J. WHITESMITH. *Improvements in power looms and in pirn winding apparatus.* Dated April 11, 1862.

This invention is not described without reference to the drawings. *Patent completed.*

1054. J. BUNNETT. *Improvements in revolving shutters and in machinery for producing the same.* Dated April 12, 1862.

These shutters are so constructed that they can also be used as venetian blinds. For this purpose such lath is mounted on a central axis, which moves up and down in the grinding shutter grooves. The upper edges of the laths are connected together by hinged flaps. A portion of the inner side of each shutter-pivot turns on pivots, and when it is desired to use the shutter as a venetian blind, this limb of the groove is turned a quarter round, when the laths are free to turn on their axes, and may be set at any required inclination. The winding pulley for raising and lowering the shutter is fitted with a friction wheel or brake, which is brought into action on lowering the shutter, but runs free when the shutter is being wound up. In order to give the required curve to the edges of the shutter-laths, a bending machine is used, by which both edges of the lath are simultaneously bent to the proper form by dies acted upon by cranks or eccentrics actuated by steam or other power. *Patent completed.*

1055. W. NUSSEY. *Improvements in machinery or apparatus for preparing and combing wool, flax, hair, cotton, silk, and other fibrous materials.* Dated April 12, 1862.

This invention is carried into effect as follows:—Firstly, the patentee employs an oscillating "feeding head," in connection with a circular or other suitable "passing comb," such oscillating head being provided with two or more nippers, or two or more pairs of rollers, or other suitable holders, which are so arranged as that each nipper or other holder may be pressed upon by a separate spring or springs; or they may be pressed upon jointly. The nippers or holders are so constructed and arranged that they can pass over the passing comb, and deliver the cleaned end of the fibres beyond the same, and as they recede leave the uncleaned ends, and noil in the passing comb at each successive stroke of the oscillating head, the latter having a rising and falling motion, as well as a forward and backward motion, imparted to it by suitable mechanical means. Secondly, he employs on the other side of the passing comb, or that furthest from the oscillating head, a comb or combs to receive the cleaned ends of the fibres which project beyond the passing comb straight and full length into the pins or teeth of the said comb or combs, such comb or combs having a rising and falling motion imparted thereto, the teeth or pins passing through a plate perforated with holes to suit (or thin bars or blades may be passed between the teeth), in such a manner that, when the comb or combs fall down, the pins or teeth fall out of the fibre and allow the latter to be carried forward by the passing comb, when the comb or combs again rise up to receive the cleaned ends of the succeeding fibres as before described. The comb or combs may also be allowed to travel a short way with the passing comb before falling down out of the fibres, and to return to the original position before rising. Or, instead of a rising and falling comb, an endless sheet or chain comb may be employed, having bars or strips of steel between each row of teeth. *Patent completed.*

1056. E. BULLEE. *A new hydraulic ram.* Dated April 12, 1862.

This consists in a method of constructing or arranging hydraulic rams, whereby the liability of the clack breaking is avoided, and the rams enabled to work even in high water. The details of the invention ate voluminous. *Patent abandoned.*

1057. A. SWEET. *Certain improvements in locks and latches.* Dated April 12, 1862.

This consists—1, in the employment of locks or latches constructed with levers or tumblers of a toothed pinion (or other equivalent arrangement), the teeth of which take into corresponding teeth or indentations formed in, or attached to, the tumblers or levers, one by one, into the position necessary for allowing the "stump" or pin (formed with or attached tt the bolt) to pass, prevent the picking of the lock by pressure, as practised with other locks. 2, In the use of a drum or tube capable of revolving on the key. This drum or tube is formed with a flat side, or other equivalent figure, which, when presented to the tumblers or levers, allows of the bolt being drawn backward from within the door to which the lock is attached without the use of a key, but which, when it is attempted to pick the lock from without, is turned away from the tumblers or levers, and prevents the drawing bach of the bolt until the tumblers or levers are raised by the proper key into a position, which brings a series of notches cut in them opposite to the stump or pin formed with or attached to the bolt, and allows of its being drawn backward (as the drum is partially revolved by the key) by a "false bit" or projection attached to and moving with the drum. In combination with this arrangement, the inventor makes use of a shield or guard plate, which prevents the introduction of a picklock for effecting the withdrawal of the bolt. 3, In an arrangement for affording additional security in locks wherein the bolt is withdrawn by means of a handle. 4, In a new permutation key, the bits of which are all of one length, and are capable of being set at various angles, so as to obtain the different amounts of lift required to operate upon the several levers or tumblers of the lock. *Patent abandoned.*

1058. E. DREWETT. *Improvements in bottles and other vessels whereby to separate and retain sediment from their contents.* Dated April 12, 1862.

According to these improvements in bottles for filtering or separating sediment from their contents, the patentee makes the bottles with a double bottom, or with a false bottom, to apply and fit closely in the bottom of the bott'e to form a chamber below it. It should fit air-tight. He makes the inner bottom of the bottle inclined instead of horizontal, as usual when the bottle stands upright, and at the lowest point (at the side of the bottle), he makes an opening into the chamber below. Instead of being a simple opening, the communication may be made with a short bent pipe passing outside of the bottle. In a bottle so constructed, sediment allowed to settle in the contents of the bottle will pass through the opening into the lower chamber, and there deposit. When sediment is so deposited, by holding the bottle in a particular position or positions, the contents of the bottle may be decanted, and the whole of the sediment retained in the lower chamber. Baths used for photographic purposes, are constructed in a similar manner, that is to say, with a double bottom, either formed of a piece with the bath, or a loose bottom fitted thereto, the inner bottom being inclined and in communication at the lowest point (at one side of the bath), for the separation of the sediment from the contents of the bottle, as before explained with reference to the bottles. *Patent completed.*

1059. A. S. CAMPBELL. *Improvements in surface condensers.* Dated April 12, 1862.

This invention relates to the condensing of the waste steam from steam engines. This effect is produced with the expenditure of a comparitvely small quantity of water, by means of the cold produced by rapid evaporations. The apparatus by which the invention may be carried out, in an economical and effective manner, consists of a number of condensing tubes, fitted at each end into a plate forming one side of a chamber, into one of which chambers opens the exhaust or steam pipe, whilst from the other or opposite chamber leads the condensed water pipe. The whole is made to rotate over a reservoir of cold water, so that the tubes will be successively immersed, and the cold produced by the evaporation of the water outside the tubes, as they rotate, effects the desired condensation of the steam. *Patent abandoned.*

1060. A. S. CAMPBELL. *Improvements in refrigeration of liquids.* Dated Apiil 12, 1862.

This consists in the use of a number of horizontal tubes fitted at each end into a plate forming one side of a chamber, into one of which chambers the liquid to be cooled enters, whilst from the other or opposite chamber the cooled liquid passes out. The whole is made to rotate over a reservoir of water, so that the tube will be successively immersed, and the cold produced by the evaporation of the water outside the tubes effects the desired refrigeration of the liquid within them. *Patent abandoned.*

1061. J. PARK. *Certain improvements in or applicable to steam engines.* Dated April 14, 1862.

The first part of this invention is chiefly applicable in works where several steam engines are employed, and it consists in connecting, by suitable pipes, the whole or any number of such steam engines to one condensing apparatus. By this means each steam engine can be worked as a condensing engine, while the construction remains simple, a in high-pressure engines. The second part of the invention is particularly applicable to the steam engines coupled direct to the rag machines employed in the manufacture of paper pulp, as described in the specification of letters patent granted to the present patentee on the 24th day of May, 1855 (No. 1,170), and consists in applying a condenser and air-pump to such engines, and in casting or otherwise making a jacket round the cylinders thereof into which the waste or exhaust steam is conveyed for keeping the cylinder warm. *Patent completed.*

1062. E. PEYTON and W. F. BATHO. *Improvements in angle iron applicable to metallic bedsteads, roofs, bridges, and other similar purposes.* Dated April 14, 1862.

Here the patentees roll or otherwise manufacture angle-iron with corrugations, by which they give it additional strength or stiffness, and are thus enabled to use a lighter bulk of metal than at present, thus combining strength with lightness of material, and giving an improved appearance to the object constructed with it, such as metallic bedsteads, roofs, bridges, and similar constructions. *Patent completed.*

1063. J. F. SPENCER. *Improvements in steam engines.* Dated April 14, 1862.

The patentee claims, in surface condensing steam engines, the combination of the fuel and condensing water pump in or within one chamber or barrel, and whether such pump be horizontal, vertical, or inclined. 2. In inverted cylinder

surface-condensing engines, the implement of a cross-head attached to the main piston or pistons by two or more rods, and connected direct at one or both ends to the buckets of one oi two combined pumps, or to one single feed and one single-acting condensing water pump, in the manner and for the purposes described. *Patent completed.*

1064. H. C. Lee. *Improvements in knitting machines.* Dated April 14, 1862.

This invention has reference to knitting machines in which sliding hooked spring needles are employed, and its objects are simplicity of construction, and the production by the machine, and with a series of needles of one gauge, of a greater variety of work than has heretofore been accomplished by machines of this class under similar conditions. The inventor employs needles, having the bend of the hook made larger than usual, so as to allow the thread or yarn to be drawn through them, and to be crimped (as described), instead of by means of jack sinkers or combs, or other ordinary appliances for taking off sufficient thread or yarn to form the loops, and laying it in proper position for the formation of the next series of loops. This operation he effects by constructing the machine with a travelling yarn carrier or thread guide, and with a travelling presser, both stationary in respect of the length or sliding movement of the needles, and with a series of stops between the needles to hold back the thread, according to the distance that the needle shall be depressed or passed beyond the stops. He produces the sliding movement of the needles by inclined surfaces in a groove or otherwise, as heretofore, but he regulates the degree of such movement by an adjustable cam in the line or path of the inclined surfaces. Instead of the ordinary presser for closing the needles, he uses a travelling rotary bar presser, which receives its motion from contact with the needles, acts as a fair leader to the thread or yarn, and by having the special peculiarity of inclined surfaces between its teeth, or between some of them, closes the needles, or some of them, accordingly as such surfaces are arranged. *Patent abandoned.*

Erratum.—No. 974 in our last No. was "completed," and not "abandoned."

PROVISIONAL PROTECTIONS.

Dated July 25, 1862.

2110. H. A. Jowett, Sawley, Derby, civil engineer. Improvements in obtaining motive power, and in transmitting the same from place to place, and in apparatus connected therewith.

Dated September 11, 1862.

2500. J. Hemsley, Melbourne, Derby, manufacturer. An improved fabric or material for scarfs, ties, handkerchiefs, and neckerchiefs.

Dated September 18, 1862.

2556. L. Mond, 38, Sidney-street, Brompton. An improved method of obtaining hypo-nitric acid and nitric acid from nitrate of soda.

Dated October 13, 1862.

2752. A. F. Gallis, 71, Dean-street, Soho. A new method of covering street omnibuses and vehicles of every description for the purpose of sheltering passengers travelling on the top of the same.

Dated October 15, 1862.

2779. J. Taylor, Oldham, cotton spinner. Improvements in temples for looms.

2781. C. De Bergue, Strangeways' Works, Manchester, engineer. Improvements in the permanent way of railways.

2782. W. Pope, Cornwall-road, Lambeth, gentleman. Improvements in coating the sides of ships, batteries, forts, or other places with defensive armour plates.

2783. P. Potenza, Naples, commander. The extraction, preparation, and spinning of the silky fibre contained in the bark of mulberry trees, and the manufacture of the same into textile fabrics.

2784. J. B. G. M. F. Piret, 29, Boulevard St. Martin, Paris, civil engineer. Improvements in lubricating apparatus.

2785. F. F. Prud'homme, 51, Rue de Malte, Paris. Improvements in machinery or apparatus for raising water.

2786. J. Bapty, Leeds, woollen yarn manufacturer. Improvements in apparatus for preparing wool and other fibrous materials.

2787. R. A. Brooman, 166, Fleet-street, patent agent. Improvements in felting machines, applicable also to the fulling, scouring, and dressing of pure and mixed woollen stuffs. (A communication.)

2789. E. A. Cowper, Great George-street, Westminster. Improvements in steam engines.

Dated October 16, 1862.

2790. W. Barningham, Pendleton Iron Works, Manchester, iron manufacturer and engineer. Improvements in the permanent way of railways.

2792. G. T. H. Pattison, Glasgow, finisher. Improvements in machinery or apparatus for embossing or finishing woven fabrics.

2793. G. T. H. Pattison, Glasgow, finisher. The imparting of an improved surface or appearance to fabrics woven with mixed materials.

2794. H. A. Remière, 52, Rue de l'Arbre-sec, Paris, harness maker. An improved horse collar.

2796. T. G. Harold, Brooklyn, New York, America. Improvements in locks.

2797. E. Humphrys, Deptford, engineer. Improvements in steering apparatus.

2798. H. Ransford, Huron Lodge, West Brompton. Improvements in building ships and other vessels.

2799. J. and J. Cash, Coventry, manufacturers. An improvement in the manufacture of valentines.

2800. J. Robinson, East India-road, surveyor. Improvements in protecting the submerged portions of iron ships, and in ventilating the cabins and cabin decks in iron ships.

2801. H. Hely, jun., Merchants Quay, Dublin, envelope manufacturer. Improvements in envelopes.

Dated October 17, 1862.

2805. J. Davis, Tipton, iron founder and engineer, and G. Davies, Tipton, ironfounder and engineer. Improvements in rotary engines, rotary pumps, and rotary blowing machines.

2806. W. S. Kennedy, Queen's-road, Bayswater. An improved method of, and apparatus for, applying fomentations and other external remedies to the throat.

2807. G. T. Bousfield, Loughborough Park, Brixton. Improvements in the manufacture of iron and steel. (A communication.)

2808. J. H. Johnson, 47, Lincoln's-inn-fields, gentleman. Improvements in the prevention or removal of incrustation in or from steam generators. (A communication.)

Dated October 18, 1862.

2809. R. Webster, Leeds. Improvements in means or apparatus for preventing or mitigating accidents arising from collisions of railway trains.

2810. E. Lord, Todmorden, machine maker. Certain improvements in machinery for opening and cleaning cotton and other fibrous substances.

2811. H. Ledger, Manchester, builder, and B. Williamson, traveller. An improved substitute for tombstones, tablets, monuments, and other similar memorials or commemorative records.

2812. J. Bentley, Denton, Lancaster, hat manufacturer. Im rovements in apparatus for forming and pressing felt hats.

2813. R. Lauth, Reichshoffen, France. Improvements in machinery or apparatus for polishing sheet iron or other metal.

2814. R. A. Brooman, 166, Fleet-street, patent agent. Improvements in frames for doubling and twisting threads. (A communicacion.)

2815. J. Fuller, Bishopsgate-street, telegraph engineer. An improvement in treating india rubber used on a wire or wires for insulating the same.

2817. W. Clark, 53, Chancery-lane, engineer. Improvements in apparatus for dredging. (A communication.)

Dated October 20, 1862.

2818. J. Tangye, Birmingham, manufacturer. Improvements in or additions to certain kinds of pulleys for raising heavy weights.

2820. R. A. Brooman, 166, Fleet-street, patent agent. Improvements in transferring designs and prints produced by photography to stone or zinc. (A communication.)

2824. J. B. Payne, Chard, Somerset, engineer and lace manufacturer. Improvements in machinery for the spinning, twisting, and doubling and laying of hemp, flax, and other fibrous substances.

2826. J. H. Johnson, 47, Lincoln's-inn-fields, gentleman. Improvements in apparatus for boiling liquids and cooking or preparing food, applicable also as a night light. (A communication.)

Dated October 21, 1862.

2830. J. Byram, Moldgreen, near Huddersfield, tinner, brazier, and ironmonger. Improvements in lamps for the combustion of paraffin, rock oil, or other oils.

2832. C. G. Clarke, Owthorn, near Hull. Improvements in garden shears.

2834. J. T. Cooke, Leicester, batten maker. Improvements in battens for weaving.

2836. G. T. Bousfield, Loughborough Park, Brixton. Improvements in the manufacture of boots and shoes. (A communication.)

2838. G. Haseltine, 100, Fleet-street. Improvements in the mode of, and in machinery for, manufacturing nails, brads, and other similar articles. (A communication.)

Dated October 25, 1862.

2872. J. Carpendale, Meadow-street, Sheffield, britannia metal smith. Improvements in the means of producing raised chasing on britannia and other compressible metals.

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

1828. F. E. Schneider, and J. Snider, jun. Breech-loading fire-arms.

1848. R. Cook. Pianoforte actions.

1849. A. Ripley. Governors or regulators.

1851. T. Carr. Machine for grinding, kneading, washing, and other like purposes.

1869. G. Turner. Applicable to machines for grinding coffee and spices.

1876. J. Parkes. Gas lanterns.

1878. J. Martin. Reaping and mowing machines.

1880. J. H. Johnson. A new composite fluid. (A communication.)

1882. J. Watson. Printing machines.

1888. R. A. Brooman. Preparing paper for the reception of photographic pictures. (A communication.)

1902. J. Petrie. Slide valves.

1922. J. M. Dunlop. Cotton gins.

1950. R. A. Brooman. Hollow plates for hydraulic presses. (A communication.)

1951. O. F. Byström. Pyrometer.

1985. H. Kellogg. Breech-loading firearms and cartridges.

2002. C. E. Green. Breech-loading firearms.

2009. J. H. Johnson. Machinery or apparatus for washing ores and minerals. (A communication.)

2120. E. Tysall. Manufacture of forks.

2126. R. Low and W. Duff. Producing an adjustable pressure on certain parts of machinery.

2130. W. Spence. Improvements in the preparation of a red colouring matter. (A communication.)

2132. W. Spence. Improvements in the preparation of a blue colouring matter. (A communication.)

2571. J. B. Giertz. Gas burners or jets.

2620. P. Wright. Parallel vices.

2655. J. Wright. Rotative travelling crane. (A communication.)

2706. J. Oxley. Expressing and separating beer from yeast or barm.

2751. G. and A. Harvey. Boring machinery.

2756. C. Thomas. Manufacture of silicate of soda or silicate of potash, and in the manufacture of artificial stone.

2762. F. G. Grice. Manufacture of nuts for screwed bolts.

2789. E. A. Cowper. Steam engines.

2811. H. Ledger, and B. Williamson. Substitute for tombstones.

2836. G. T. Bousfield. Manufacture of boots and shoes. (A communication.)

The full titles of the patents in the above list can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list who have given notice of their intention to proceed, within twenty-one days from the date of the *Gazette* in which the notice appears, by leaving at the Commissioners' office particulars in writing of the objection to the application.

LIST OF SEALED PATENTS.

Note.—Specifications will be forwarded by post from the Great Seal Patent Office (publishing department) on receipt of the amount of price and postage. Sums exceeding 5s. must be remitted by Post Office Order, made payable at the Post Office, High Holborn, to Mr. Bennet Woodcroft, Great Seal Patent Office.

THE
MECHANICS' MAGAZINE.

LONDON, FRIDAY, NOVEMBER 14, 1862.

THE FOREIGN LOCOMOTIVES IN THE INTERNATIONAL EXHIBITION.

THE locomotives in the western annexe have as yet remained comparatively untouched in the universal devastation going on round about them, and they yet stand up like so many antediluvian monsters in the midst of a surrounding chaos. Amongst these twenty engines, nine are from the continent, namely, three from France, four from Germany, one from Belgium, and one from Italy; and some of these latter have had to undergo some rather severe criticism at the hands of English engineers. There is no doubt that these foreign engines contrast unfavourably with the severe simplicity that characterises most of our own productions in this line.

It appears to us, however, that English engineers have not fully taken into account the very different circumstances existing on the continent. Fuel is almost everywhere very much dearer and inferior than with us. Some continental countries have even to fetch all their coal from England. For instance, English coal competes, for some purposes, with German lignite, as far up the Elbe as Prague. Economy of fuel cannot be obtained without some complication and additional details. On many of the foreign lines, particularly in France, the engine-drivers are allowed a percentage upon any saving of fuel they may effect. They are thus more willing than our engine-drivers to adopt any improvement, even if that improvement should involve additional trouble. Many an engineering novelty, in the workshop as well as on the line, has, in England, been "burked" by the unwillingness of the "hands."

Capital being very dear with the continental nations, their lines have been laid out witn the least possible first cost. Steep inclines and curves of a small radius, the abominations of the Stephensons, have for this, among other reasons, been brought into their railway practice. Heavy engines, their weight giving adhesion for the steep inclines, with arrangements to pass round the sharp curves, have thus been necessitated; Robert Stephenson's plan of using two four-wheeled engines, coupled back to back, being rejected on account of the expense in fuel of this arrangement. The cost of manufacture and repairs involved in additional complication is not so much felt with them, as a good fitter does not get more than a labourer with us; indeed, in some districts, not so much. Time is not worth so much money on the continent as in England, and thus the passengers and mails are not required to be propelled with English speed. The "paternal governments" also having made exclusive monopolies of the railway lines, have prevented all competition. As long as the subjects of these Governments do not interfere with politics, very great care is taken with the necks of the loyal lieges, and decisions about accidents are not left to the caprice of a jury.

The slower speeds thus permitted to these railway companies allow of somewhat more complication than could stand the wear and tear that the English locomotive engine has to undergo; for it is "pace" that kills the iron horse, as well as his flesh and blood prototype. English and continental railway practice can scarcely be compared, they are so different. One difference would, perhaps, touch the heart of some English shareholders, and that is the high dividend of many continental lines. These dividends are shared in many cases with all the employés, from the highest manager to the lowest engine-driver. If railway directors were always paid in proportion to the profits, perhaps railway property would become more valuable than it generally is in England. Perhaps, also, it may be wholesome to our insular pride to remember that some of the most important improvements made in locomotives since 1851 have been imported from abroad. We owe the introduction of Giffard's injector to France. Bogies and trucks are American improvements. We still fetch our steel tyres and steel cranked axles from Prussia, the latter to meet our persistent adherence to inside cylinder engines. This expensive form of engine has been abandoned for several years in Germany and America. Having at last settled down to some simple coal-burning schemes, we find out that the Americans have preceded us in this improvement in locomotive practice, and we no longer attempt to burn coal by building up coke ovens inside our fire-boxes.

The light pistons, so much used now for locomotives, are of Swedish origin; Mr. Ramsbottom, of Crewe, having designed his well-known piston after a Swedish model. Abroad, this piston is generally known under the name of the Swedish piston. We may sneer at the Austrian 4-cylinder express engine, for its complication, but after all it is the only locomotive engine in the Exhibition perfectly counterbalanced for all speeds. An important improvement, of English origin, invented since 1851, is Mr. Ramsbottom's scoop for feeding a tender while in rapid motion. The action of this device may, perhaps, be shortly explained, by terming it a centrifugal pump with an infinitely large radius. The engine and tender, from the Crewe shops of the London and North Western Railway, embodying this arrangement, and those close by of Messrs. Berger, Peacock, and Co., of Gorton, near Manchester, may be looked upon as the *élite* of the locomotives in the western annexe. These two illustrate, in a remarkable manner, the general difference between engines issuing out of private workshops, and those made in railway companies' workshops. The Gorton exhibit is the very embodiment of locomotive beauty and simplicity. Every curve about it has evidently been made a special study, and has been carefully worked out on paper before being carried out in the shop. Almost every detail is the most simple that could be chosen for its particular function, and they have all been put together with the most perfect regard for symmetry.

The driving wheels are 7 ft. in diameter, and the leading, trailing, and tender wheels are 3 ft. 9 in. in diameter. The total length of wheel-base is 15 ft. 4 in., and it is equally divided on each side of the driving-wheel. The cylinders are 16 in. in diameter, 22 in. stroke. There are bearings inside for the crank axle, and outside bearings for the two others. The fire-box, of copper, is 4 ft. 3 in. long, 4 ft. 3 in. wide, and 5 ft. 9 in. deep. The boiler is 4 ft. 2 in. in diameter, with 215 2-in. diameter tubes, 11 ft. long. These dimensions give 18 square feet of grate surface, 96 square feet of fire-box surface, and 1,236 square feet of tube surface; the total heating surface being therefore 1,332 square feet. The 6-wheeled tender holds 1,750 gallons of water and 1½ tons of coal. The engine, when full, weighs 28 tons 6 cwt. The fire-box is arranged to burn coal, there being placed within it a deflecting plate or hood, causing the cold air from the fire-box to impinge upon a fire-brick arch thrown across the fire-box. The firedoor itself is of the "Midland" kind, the links and handles working the two slides being of a rather heavy pattern. This inside cylinder engine is intended for Portugal—the Portuguese guage, 5 ft. 6 in., giving ample room for the arrangement of the working parts. The link motion used is Allen's straight link. We suppose that the only impediment to the universal introduction of this elegant and light form of the link motion is the royalty to be paid for its use, as we believe that the patent for it is not yet expired. As far as we could tell by an outside inspection, there did not appear to be the slightest originality or novelty about this engine.

It seemed to us to stand there and to say: "Locomotive practice has reached its culminating point, and I embody its highest perfection." Is this the case? We very much doubt it, and we believe that another decade will witness some great changes in this direction also. It is not very easy for a private locomotive maker to advance locomotive practice. He does not see the locomotive at its work. He does not know all the requirements of a railway line. He does not "walk the "hospitals" of the repairing shop. All that he can do has been achieved in this Gorton engine. Practical mechanics are so much of an experimental science, that if a private manufacturer were to try new arrangements, he would, probably, very soon scheme himself out of all his custom. Accordingly, we see that most of locomotive improvements in detail, of late years, have been introduced by the engineers of companies. Whether these experiments, sometimes resulting in successes and as often or oftener in failures, have in all cases been carried on in a perfectly fair way as regards the interests and dividends of the railway companies, we will not at present inquire.

The Crewe engine is literally an embodiment of unimpeded progress, as one of the 170 similar ones in use on the London and North-Western Railway has run the distance of 131 miles without stopping. The different details about this engine and tender, such as the picking-up scoop, the duplex safety valve, the flush boiler, the pistons, the cylinder lubricating apparatus, the screw reversing gear, the coal-burning arrangement, the communication between guard and engine-man, render it the most complete engine in the whole annexe. The driving wheels are 7 ft. 7½ in. in diameter, the leading and trailing wheels only 3 ft. 7½ in. The wheel base is 15 ft. 5 in., 7 ft. 7 in. between the leaving and driving, 7 ft. 10 in. between driving and trailing wheels, 9 ton 8 cwt. are on the leading, 10 ton 10 cwt. on the driving, and 6 ton 2 cwt. on the trailing wheels when the engine is full. The outside cylinders are 16 in. in diameter, and 24 in. stroke. The grate surface is 14½ square feet. The fire-box heating surface is 85 square feet, that inside the 192 tubes 915 square feet, making up a total of 1,000 square feet. The tender carries 1,500 tons of water and 2 tons of coal. The boiler is fed with two Giffard injectors, No. 10 size, no other feed apparatus being used. The fire-box is arranged for burning coal, the air being admitted through two openings in front, and deflected on to the fire by a brick arch across the fire-box. This is regulated by the engine-man by means of dampers. There is a hopper in the smoke-box to receive any particles of unconsumed fuel that may be carried through the tubes. They

are discharged through an opening in the bottom of the hopper.

The screw reversing gear has, no doubt, several advantages over the ordinary reversing lever, but in case it be required to reverse the engine very suddenly, as, for instance, to avoid a threatened collision, we do not see that this could be done so quickly as with the ordinary reversing gear.

We will now try to describe some of the foreign engines exhibited. They will, no doubt, contrast unfavourably in many respects with the above two English express engines, but, as we explained before, the different circumstances under which they were manufactured, and are to be employed, must be taken into consideration. The Northern Railway Company of France send an eight-wheeled coupled goods tank engine, burning coal. It was made by Messrs. Ernest Gouin and Co., after the designs of M. Jules Petiet, engineer of the railway company, who have also sent the drawings of two other engines, one being a ten-wheeled passenger, the other a twelve-wheeled goods engine, both with four cylinders.

The company have printed a small pamphlet, intended for the use of the Jury, called "Notice sur les trois types de Locomotives Exposées," from which we extract the principal part of the following account of these very remarkable engines. They style the engine exhibited "Le Dromadaire," and it certainly is a very ugly animal. Without completely subscribing to all the opinions therein contained, we believe that it will be found an interesting exponent of French locomotive practice:—

In the locomotives exhibited, the fire-box is placed above the wheels and frame plates, thus affording the means of giving it a much greater width (5 ft. 9⅞ in. and 5 ft. 10⅞ in.) By doing this a greater number of tubes may be placed in the boiler, and a larger surface of grate obtained without lengthening the boiler. It is obvious that, for the combustion of fuel of inferior quality, the area of the grate must be increased. The fire-grates of these locomotives are all made according to the plan patented by M. Belpaire.* Eleven locomotives, similar to the one exhibited, are working very successfully on the Northern line, and burn only slack coal. This one has a fire-grate 4 ft. 10 in. by 5 ft. 9⅞ in., equal to 28.20 square feet. The four cylinder passenger and the four cylinder goods engine have respectively a fire-grate surface of 4 ft. 10 in. by 5 ft. 9⅞ in. equal to 28.20 square feet, in the first case, and 6 ft. ¾ in. by 5 ft. 10⅞ in., equal to 35.84 square feet, in the other. The roof of the fire-boxes of these engines, like the sides of ordinary fire-boxes, is formed of two parallel plates held together by stay-bolts. The lengths of the tubes are 11 ft. 5¾ in., with an outside diameter of 1 37-64 in. This small diameter allows us to reduce the average thickness of metal to 1-16th of an inch. In order to allow of a greater number of tubes with the same diameter of boiler, its steam-room is lessened, and a tubular steam chamber is placed on the top, surrounded completely by the heated gases from the main boiler. The engine is thus supplied with a second steam-chamber, or drying apparatus, the object of which is to dry the steam, and thus to obviate the priming to which the main boiler would be otherwise subject from its small steam-room. The heating surface of this drying apparatus varies in the different engines from 139 to 150 square feet. In the passenger engine, with four cylinders and two driving axles, the diameter of the barrel of the boiler is 4 ft. 2 15-16 in., the heating surface of the fire-box 109 square feet, of the tubes 1,558 square feet, of the drying apparatus for the steam 129 square feet; total, equal to 1,796 square feet of heating surface. The heavy gradient goods engine, four coupled axles, exhibited, has a boiler 4 ft. 2¼ in. diameter of the barrel, with 109 square feet of fire-box, 1,558 of tube surface, 129 of drying apparatus; total, equal to 1,796 square feet of heating surface. The engines with four cylinders have a 4 ft. 9 in. diameter boiler barrel, 108 square feet of fire-box, 2,034 tube surface, 154 drying apparatus; total, equal to 2,296 square feet of heating surface.

The elevation of the grate of these engines above the hind wheel, and the position of the steam-chamber and smoke-box above the boiler, do not permit of a vertical chimney of sufficient length. It has therefore been placed horizontally. The total weight of this kind of engine, in proportion to steam-producing power of the heating surface, is about 53 lbs. per square foot of heating surface.

In this pamphlet it is stated that railway companies have for some time been obliged, from occasionally working heavily laden trains on heavy gradients, to have powerful passenger engines constructed, and to adopt almost always the coupling by means of rods of two of the axles. But this coupling becomes inconvenient for express trains, having to go at a speed of more than 38 miles per hour, as the diameters of the four wheels do not always remain the same. After some time, one pair of the wheels having had more wear than the others, their diameters become smaller, which produces extra friction, and has the effect of straining the coupling rods. Besides which, these rods being of considerable weight, are subject to break when the train is running at a high speed. It is not, therefore, without some misgiving that locomotives with coupled wheels are made use of for high speeds; locomotives with independent wheels being preferred, and a heavier load being then put on the driving axle. But this case, putting aside the damage undergone by the rails, the tyres of the wheels wear out rapidly, and when atmospheric influences are not favourable, the adhesion to the rails is not sufficient, and the wheels slip.

They state that these reasons have led them to order the four-cylinder locomotives, the drawings of which they sent to the Exhibtion. The boiler of these engines is in every way similar to that of the heavy gradient locomotive. It can, therefore, truly be placed on a low framing, and above the bearing wheels, measuring 3ft. 6 in. in diameter. The extreme axles are at a distance of 16 ft. 11 9-16th in. from each other.

The small diameter wheels weigh little, and consequently require but a short and light framing. The power being divided between four cylinders, the pistons, as well as the connecting rods, and the whole mechanism, are smaller and of less weight. The four-cylinder passenger engine, with 7 tons weight of water, 2 of fuel, and a heating surface of 1,796 square feet, weighs 48 tons.

There is a separate steam regulator for each pair of engines. The pressure of the steam in the boiler is 118 lb. The diameters of the cylinders are 14 3-16th in. The stroke of piston is 13 7-16th in.

As we stated before, the engine actually exhibited is a goods tank engine, 8-wheeled, coupled, and burning coal. The other goods engine, with 4 cylinders, 12-wheeled coupled, is shown in a drawing.

The following table gives a comparison of the principal dimensions of these two goods engines:—

	Heavy gradients. Four axles coupled.	Four cylinders. Six axles coupled.
Area of grate	28·2 sq. ft...	36 sq. ft.
Total heating surface ...	1,796 sq. ft...	2,296 sq. ft.
Pressure of steam	118 lbs.	118 lbs.
Diameter of cylinders...	1ft. 6 7-8in...	1·4 ft. 9-16 in.
Stroke.......................	1ft. 6 7-8in...	1·5 ft. 5-16 in.
Diameter of wheels	3·6 ft.	3·6 ft.
Weight on driving wheels, engine full	42·3-4 tons...	56 3-4 tons.
Weight of engine full ...	42 3-4 tons...	56 3-4 tons.
Weight of engine, &c., per square foot of heating surface	53 lbs...........	55 lbs.

The steam drying apparatus of all these three kinds of engines is made of iron tubes, 3⅛ in. outside diameter, and ⅛ in. thick. The tubes are fastened without ferules. The heated gases pass round the chamber and through the tubes. The foot-plate is 5 ft. long for the heavy gradient engine exhibited, and 5 ft. 7in. for the two four-cylinder engines. The ash-pan is in three parts. The centre part has the shape of a double-inclined plane, to catch the air in both directions of running, and to drive it towards the grate. There are two Giffard's injectors on the boiler. The boiler is fixed to the framing at the two ends only. The wheels are of wrought iron, and have balance weights forged on them. The reversing gear is double, and is worked by a rod on each side of the engine.

II

(To be continued in our next.)

LIVES OF THE ENGINEERS.*

(SECOND NOTICE).

On Stephenson's return from Scotland, he found that his father had met with a serious accident, and which had been the means of reducing him to a state of extreme poverty. "While engaged in the inside of an engine, "making some repairs, a fellow workman "accidentally let in the steam upon him. "The blast struck him full in the face; he was "terribly scalded, and his eyesight was irre- "trieveably lost." George's return was therefore opportune, for none of the family save himself were in a position to assist their parent in his hour of direst need. To pay off the debts which the old man had contracted, and which amounted to £15, was the first act of the dutiful son, and the next was to remove his parents to a comfortable cottage near the West Moor, at Killingworth. In this cottage they lived for many years afterwards, George being their sole supporter. For himself he obtained employment once more in his position as brakesman, at the West Moor Pit. His hopes at this period were not of the brightest hue. Indeed, it is notorious, that in 1807-8 the condition of the working classes in England—thanks to the war which then raged—was bad in the extreme. George Stephenson, with many of his co-workers, was drawn for the militia. All the money he had saved, and six pounds which he borrowed, were devoted to the payment of a substitute, and thus he was reduced to severe straits. It was at this juncture that he contemplated emigrating to the United States. Fortunately for his native land, he could not raise sufficient money for the realisation of this project. The intensity of his feelings, however, may be imagined from a remark which he subsequently made to a friend on the subject. "You "know," he said, "the road from my house "at the West Moor, to Killingworth. I re-

* This will be described in our next number.

* Lives of the Engineers, with an account of their Principal Works; comprising also a History of Inland Communication in Britain. By Samuel Smiles. With numerous Portraits and Illustrations. Vol III.; George and Robert Stephenson. London: John Murray, Albemarle-street, 1862.

member once when I went along that road I wept bitterly, for I knew not where my lot in life would be cast."

It has been said, and the truth of the saying has often been experienced, that "the darkest "hour is that before the dawn," and it was essentially so in the case of George Stephenson. He was not the man to yield to despair, and in conjunction with two other brakesmen, "he took a small contract under the colliery lessees for breaking the engines at the West Moor Pit." Many improvements were made by the trio in the mechanical and other arrangements connected with the works, and they resulted in saving to the owners of the pit, and profit to themselves. The experience thus gained fitted Stephenson for other and more important undertakings. In 1810 a pit was sunk by the "grand allies" (the lessees of the mines) at Killingworth. An atmospheric or Newcomen engine, originally made by Smeaton, was fixed there for pumping water from the shaft. From some defect or other in its construction, it failed to do its work efficiently. Naturally this engine attracted the attention of the workmen generally of the district, and of Stephenson among the rest. He had, indeed, watched its erection and foretold its weakness. Further inspection followed, and having expressed an opinion that he "could alter her, and make her draw," Mr. Dodd's, the head viewer of the mines, determined to allow him to try his hand at the task. "The engineers hereabouts," said Mr. Dodds, "are all beat, and if you can succeed in accomplishing what they cannot do, you may depend upon it I'll make you a man for life." Stephenson first stipulated for the removal *pro tem.* of the old hands, who were jealous of his interference, and then set himself, with a party of men he had selected, in earnest to the work. "The engine was taken entirely to pieces. The cistern containing the injection water was raised ten feet; the injection cock was enlarged to nearly double its former size, and it was so arranged that it should be shut off quickly at the beginning of the stroke." It was found also that the boiler would bear a greater pressure than five pounds, and, contrary to the instructions of both Newcomen and Smeaton, Stephenson determined to load it up to a pressure of ten pounds. In three days the alterations were completed, and when the engine was again started, it performed all that was required. The pit was drained, and the workmen were "sent to the bottom."

For this work Stephenson received "the biggest sum of money he had ever before earned in one lump." In addition to this Mr. Dodds appointed him engineer at the High Pits, and his reputation as an engine-doctor spread far and wide. Other achievements followed this success, and in 1812 Stephenson was appointed engine-wright at Killingworth High Pit, at the salary of £100 per annum, under the "grand allies," a company, it may be well here to state, consisting of Sir Thomas Liddell (afterwards Lord Ravensworth), the Earl of Strathmore, and Mr. Stuart Wortley (afterwards Lord Wharncliffe). Thus, then, by dint of perseverance, observation, and industry, had George Stephenson advanced to a position of comparative honour and responsibility, and it is impossible not to draw from his career, lessons of encouragement and hope. With the same certainty that a man who puts alternately one foot upon the step above that upon which the other rests, will ascend a ladder, had Stephenson advanced from the cowherd to the engine-wright. He had learnt and practised the poet's injunction—

"Honour and fame from no condition rise;
Act well your part, there all the honour lies."

At Killingworth Stephenson devoted some attention to that *ignis fatuus* which has misled in times past so many clever men, and which yet has here and there a follower—perpetual motion. His efforts were, of course, futile, but the mechanical practice which he gained from the prosecution of abortive schemes was not without its value. He put himself, too, under the tuition of John Wigham, a man of "letters" and of "figures," and thus added to the scanty knowledge he had gained under Robin Cowens and Andrew Robertson. Another consideration now weighed with him, and this was the education of his son. It may suit the purpose of the *Athenæum*, sometimes unjust, and frequently ungenerous, to attempt, as it has done in its last issue, to rob the father in this case of the merit of attending to his son's education, but there is abundance of evidence, we believe, to sustain Mr. Smiles's statements. Robert Stephenson was sent, in the first instance, to the roadside school at Long Benton, kept by Rutter, the parish clerk, and there gained such rudimentary instruction as that functionary was only able to give him. In 1815 he was sent to Mr. Bruce's school, in Newcastle, being then twelve years of age. "His father bought for him a donkey, on which he rode into Newcastle and back daily; and there are many still living who remember the little boy dressed in his suit of homely grey stuff, cut out by his father, cantering along to school on his 'cuddy,' with his wallet of provisions and his bag of books slung over his shoulder." His progress at Bruce's academy is said to have been "satisfactory though not extraordinary," and, so far as he could, the elder Stephenson supplemented the information the boy obtained at school by practical lessons at home. Mr. Smiles describes pleasantly a visit which, in company of Mr. Robert Stephenson, he paid in 1854 to the neighbourhood in which the boyish days of the latter were spent, and gives the substance of their conversation. This, though exceedingly interesting, cannot be transcribed here. We all know what early recollections are, and how deeply the incidents and accidents of school days remain imprinted on the mind. In Robert Stephenson's case this was remarkably so, but we must leave the proof of it to be discovered in the chronicles of the "Lives of the Engineers."

Whilst the elder Stephenson was at the High Pit, he devoted such leisure time as he had to the repairing of clocks, and thus added somewhat to his income. It was at the same time that he constructed a sun-dial, which still exists and testifies to his ingenuity, while it tells of the flight of the hours. The temptation to linger over the early reminisences of the two great men, whose characters are depicted so well by the author of the work under notice, is great, but space warns us not to do so.

In Chapter six, we find an excellent sketch of the history of the locomotive engine, and this almost deserves quotation in its entirety.

The first locomotive made by George Stephenson was tried upon the Killingworth Railway, "on the 25th July, 1814." On an ascending gradient of 1 in 450, the engine succeeded in drawing after it eight loaded carriages, of thirty tons' weight in all, at about four miles an hour. This was, of course, a rough specimen. The parts were huddled together, and its jolting motion soon disarranged everything. It was, indeed, considered to be next to a failure, and had not Stephenson applied to "Blutcher"—for such was the popular name given to the engine—the steam-blast, it probably would have been a complete failure. The application of the steam-blast proved to be the salvation of the scheme; and so confident was Stephenson now of future success, that he took out a patent dated 28th February, 1815, for a locomotive engine, which combined many excellent points. An engine was constructed on this principle before the close of the year, and it may fairly be regarded as the type of the locomotive of the present time. The story of the invention of the "Geordy," or safety lamp, is already well known, but ampler particulars in reference to its origin are furnished by Mr. Smiles. The risks which the inventor ran in testing it practically are also made apparent in the "Lives," and they go to prove the courage and determination of the man. Into the rival claims of Sir Humphrey Davy and George Stephenson for priority in the construction of a safety lamp, we cannot go. It is likely that the inventions were parallel and independent. Both inventors, therefore, are entitled to equal honour. To this day the "Geordy" lamp is used in the Killingworth Collieries, while elsewhere the "Davy" flourishes.

Many alterations in the internal economy of the mines with which Stephenson was connected owed their origin to his fertile mind and inventive skill, and most of these were attended by practical benefit. He however, began next to pay attention to the construction of the railways in connection with the mines. "All railways were at that time laid in a careless and loose manner, and great inequalities of level were allowed to occur without much attention being paid to repairs." These evils Stephenson sought to remedy, and his efforts were successful to a considerable extent. One great improvement made was in altering the system of jointing the rails; he substituted a *half-lap* for the *butt-joint* previously in use, and contrived for it a new kind of chair for supporting the rails. These changes were embodied in a patent, which, in conjunction with Mr. Losh, an iron-founder of Newcastle, Stephenson took out in September, 1816. In the same patent some modifications of the locomotive were also embraced, and it is a fact that some of the engines made by Stephenson in the year just named are still in use at the Killingworth Collieries. The application of steam to travelling on common roads obtained, at the instance of friends, a share of our engineer's notice about the year 1818, and in conjunction with Mr. Nicholas Wood he conducted some experiments to this end. Stephenson soon became disenchanted of the notion, and advised others to relinquish the attempt. His judgment, as we now know, was sound, and although Traction engines of admirable construction and great power are at present successfully employed, it is not likely that the locomotive will ever be made to serve in the place of horses on common roads.

The opening of the Hetton Railway, in 1822, was a great triumph for George Stephenson. He had remodelled the line on his own plans, and five of his locomotives were on the 22nd of November in that year set to work upon it.

Meantime, Robert, who was now serving in the capacity of viewers' apprentice, at Killingworth, assisted his father, so far as possible, in the realisation of his schemes, "the two working together as friends and co-labourers," and their evenings were spent in profitable study. In the year 1820 it was determined that Robert should go for a time to the Edinburgh University, and as is well known, this wise resolution tended immensely to the well-being of the student. While at Edinburgh, his conduct was marked by strict application, and

the sure result followed; his mind was prepared for the conception of designs for the great works he was afterwards destined to achieve. At the University he obtained the prize for mathematics, and after six months' sojourn there he returned to Killingworth, and re-entered upon the active business of life. Of the elder Stephenson's association with Mr. Edward Pease, the projector of the Stockton and Darlington Railway, most persons are aware, but Mr. Smiles, by aid of that persevering spirit of inquiry which distinguishes him, has been enabled to furnish many new facts in relation to it. Of Stephenson's survey of the line, of his appointment as engineer to the Company, and the opening of the railway on the 27th of September, 1825, we are told; but for these doings, and other interesting particulars in reference to them, we can but suggest that the reader should refer to the pages of the "Lives of the Engineers." So far as the carriage of coals upon the line was concerned, it was a great success, and now came another epoch of improvement. It was suggested that passenger traffic should be commenced, and to this object Stephenson turned his attention. A coach, or rather a caravan, was built under his direction at Newcastle, and this was christened by its parent "The Experiment." "A row of seats ran along each side of the interior, and a long deal table was fixed in its centre. The company's arms were afterwards painted on its side, with the motto, 'Periculum privatum utilitas publica.' Such was the sole passenger-carrying stock of the Stockton and Darlington Railway in 1825. . . . . The 'Experiment' was fairly started as a passenger coach on the 10th of October of the year in question." It was drawn along the rails by one horse, and "did" the distance of twelve miles in two hours. The fare charged was 1s., without distinction of class. Such was the beginning of that mighty traffic which is now carried on through the jungles of India and the bush of Australia, and which will in time extend itself to every part of the globe where the adventurous foot of man is likely to be planted.

It is necessary to pass on now to the period of the projection of the Liverpool and Manchester Railway. In the work before us, a *resumé* is given of the means by which, in the teeth of great opposition, Stephenson pursued the object which, in his mind, he had determined should be attained. To Thomas Gray and to William James their fair share of credit is given in relation to the matter. The Parliamentary battles which had to be fought and won are all detailed with adequate minuteness. The Bill was defeated in the first instance, much to poor Stephenson's dismay; but, as has been shown before, he was not the man to be beaten, either by men or circumstances, and he patiently bided his time. Meanwhile, a new survey was made of the proposed line, and this was conducted by Messrs. George and John Rennie, whose names thus became imperishably and honourably associated with the Liverpool and Manchester Railway. Mr. Charles Vignolles was appointed to prepare the plans, under the direction of the Messrs. Rennie.

All being prepared, another Parliamentary campaign was commenced, and this time the victory was to the engineers. In the course of the final discussion some extraordinary speeches were made in both houses against the project, and Sir Isaac Coffin delivered himself of certain prophetic warnings which, could he have peeped only a few years into the future, would assuredly have remained coffined in his own breast. "What was to become," he asked, "of coach-makers and harness-makers, of coach-masters and coachmen, of innkeepers, horse-breeders, and horse-dealers? Was the house aware of the smoke and the noise, the hiss and the whirl, which locomotive engines passing at the rate of ten or twelve miles an hour would occasion? Neither the cattle ploughing in the fields, or grazing in the meadow, would behold them without dismay. Iron would be raised 100 per cent. in price, or more probably exhausted altogether! It would be the greatest nuisance, the most complete disturbance of quiet and comfort in all parts of the kingdom, that the ingenuity of man could invent!" These eloquent remarks, as we know, failed completely in covincing the "House," and this consummation was due largely to the influence of the gifted but unfortunate Mr. Huskisson. The cost of obtaining the act, nevertheless, was £27,000.

George Stephenson was presently appointed engineer to the company at a salary of £1,000 per annum, and he straightway removed to Liverpool. The story of the difficulties overcome at Chat Moss and other places, is a thrice told tale, but Mr. Smiles invests it with new interest. Let us, however, for the present leave the sturdy engineer to his gigantic labours, and return to his son. Robert had assisted his father in superintending the works of the Hetton, and the Stockton and Darlington Railways. In 1824, he accepted an engagement under the Colombian Mining Association, and proceeded to South America to assist in the working of the gold and silver mines in New Granada, or Colombia. Three years at this place sufficed for him, and disease drove him home in 1827. He next assisted his father with counsel and advice in regard to the work upon which he was engaged. Of the details of the trials of the "Rocket," and other locomotives, all mechanical men are aware as they are of those of the opening of the Liverpool and Manchester Railway, on the 15th of September, 1830. These are amplified upon in the book under notice, and may be read again with fresh interest by many, coming as they do from the graceful pen of its accomplished author.

The next great step in railway works was the construction of the London and Birmingham line, and here the talent of Robert Stephenson found "ample room and verge "enough" for its development. Chapters 15 and 16 are devoted mainly to the history of the formation of this then stupendous undertaking, and an account of its opening in 1838. Most of the great engineering works of Robert are eloquently and elaborately discoursed upon by Mr. Smiles in the concluding part of the volume. The period of the railway mania, the rise and fall of King Hudson, and all the concomitant circumstances in connection with that period, are dealt with. The opinions of George Stephenson on many interesting questions of a mechanical nature are also recorded, and at last we reach the fatal hour when his indomitable spirit succumbed to the King of Terrors. At the age of sixty-seven, and on the 12th of August, 1848, George Stephenson died. Of the services which he rendered, not only to "the State," but to humanity, it is not necessary further to speak. His career is one which all may study with profit, and his example should serve to arm those who are struggling against difficulties, with unquenchable energy.

The statue of the great man, recently erected in Newcastle, is in every way worthy of him, as it is an exemplar of the brilliant talent of the sculptor, John Lough. It stands in a thoroughfare frequented by working-men, and as Mr. Smiles suggests, we can imagine them looking up to his manly face there depicted, and repeating the words which Robert Nicoll addressed to Robert Burns:—

> "Before the proudest of the earth
> We stand with an uplifted brow;
> Like us thou wast a toiling man—
> And we are noble now!"

We have left ourselves but little space for noticing the last few years of Robert Stephenson's life, and the vast achievements he effected during them. So recent is his departure from among us, and so well known are most of his works, that we regret this the less.

On the 12th of October, 1859, the end came, and the grave closed over the worthy son of a worthy father. Peace be unto both!

We must not omit to state that the third volume of the "Lives of the Engineers" is admirably illustrated, as its predecessors were, and that in all other appointments it is excellent.

INTERNATIONAL EXHIBITION.

JURY REPORTS.

CLASS XXXII.—STEEL.

SECTION A.—*Steel Manufactures.*

JURY.

J. Brown, President of Section, Sheffield; Mayor of Sheffield.
Frémy, Deputy-Chairman, France; Member of the Institute; Professor at the Museum of Natural History, and at the Polytechnic.
Robert Jackson, Secretary, Sheffield; Steel Manufacturer.
Thomas Jessop, Sheffield; Steel Manufacturer.
Dr. Karmarsch, Zollverein; Director of the Royal Polytechnic school, Hanover.

The Jury of Class XXXII. have the honour briefly to report on the various articles which have been submitted to their examination, and also to offer a few observations relative to the progress and present position of some of the trades which have come more immediately under their notice.

They met for the first time on the 7th of May, and elected a deputy-chairman, two presidents of sections, and two reporters.

Having ascertained that very few of the foreign exhibits were ready for inspection, they adjourned for a week, when they again met, and commenced their examinations, which were continued till the 30th of May, and on that day their awards were finally agreed upon and duly noted by the Hon. Mr. Portman, Deputy-Commissioner of the class.

The whole number of exhibitors whose contributions came under their examination appears to have been—

From the United Kingdom..........	130
From the British Colonies............	18
From Foreign Countries..............	136

This statement, however, is not strictly in accordance with the Official Catalogue, which contains the names of several, no doubt intending exhibitors, but whose contributions never arrived; while on the other hand, the names of a few foreign exhibitors, whose productions arrived late, are omitted.

They were also called upon to examine some contributions appearing in other classes, but which evidently belonged to Class XXXII. If, therefore, the contributions of any exhibitor should have escaped observation, the Jury can only attribute this omission, either to the lateness of arrival, the delay in arrangement, or error in classification.

Steel and Steel Manufactures.

The Jury consider the most important branch of industry in this class is that described in the Jury Directory under Section A, as "Steel and Steel Manufactures."

It seems, however, somewhat strange tha light and fancy articles, such as steel pens, needles, fish-hooks, and steel toys, should have been put in this section, while the heavier steel goods such as scythes and sickles, files, and edge tools

are classed with knives, scissors, and razors in Section B.

The origin and progress of the steel trade are at the present time so well known (the subject having of late years occupied the attention of many eminent writers), that to give in this report even a brief sketch of its history would seem to be out of place; yet it appears desirable to direct attention to its development since the Exhibition in 1851.

Patents for Improvement in the Manufacture of Steel.

During the last eleven years, from May, 1851 to May 1862, no less than 177 applications for patents have been made for improvements in the manufacture of steel, and 127 of these have been actually sealed.

This statement evinces the deep interest which is felt by scientific and practical men of the present day in reference to the productfon of this, the most useful of metals, and also to the desirability of improving its quality, cheapening its price, and of being able to make it with certainty ot such a uniform character, that it may be specially suitable for the various purposes for which it is required, whether those purposes be the watch-spring, the lancet, the razor, the railway-wheel, or the heavy crank-shaft of the steam-engine.

Yet out of these 127 patents there is only one which had brought about any striking change in the mode of producing steel, or which has been attended with any real practical or commercial results—and this is the process patented by Mr. Bessemer.

Bessemer Process.

And even Mr. Bessemer does not contemplate that the metal or steel made by this process will supersede the steel made in the old-fashioned way, but rather that it will become a substitute for wrought-iron, in most cases where large masses of metal are required.

The Jury think it right to state in this report what in their judgment are the peculiar characteristics of the Bessemer metal or steel: this judgment having been formed partly from their own experience and partly from information received from Mr. Bessemer and other scientific and practical men, some of whom have both worked the process and used the metal.

When nearly decarbonised it is a soft homogeneous useful metal, suitable for cannon, ship and boiler plates, piston-rods, slide-bars, and generally for large forgings for constructive purposes; but when in this state it will not harden, and can be welded only with difficulty. It is, therefore, obvious that for all purposes where the welding property is required, or where hardness combined with toughness and elasticity are essential, or for articles capable of receiving a high polish, or sustaining a fine and keen-cutting edge, this is not the right sort of metal or steel to use.

When a larger proportion of carbon is left in the metal, it is then difficult to obtain uniformity of temper or quality, and there is no certainty even that all the ingots from the same conversion will prove workable.

Experience has also shown that the quality of the produce by this process, as by the old one, depends in a great measure on the nature or properties of the material used.

Good Bessemer metal cannot be produced from inferior or unsuitable pig iron.

A scientific and thoroughly practical man, in writing to one of the Jury, gives the following opinion of the Bessemer metal:—

"The difference between the first-class steels made in the old way from Swedish steel irons, and the metal or steel produced by the Bessemer process seems to be this: that in the former several good steely qualities are combined, constituting their excellence; while in the latter it is difficult, at present, to obtain in one piece more than one of these qualities; for instance, if left hard it is not tough, and if left soft and tough, it will not harden.

"Time, aided by skill and experience, will, no doubt, cure or remove some of these faults or deficiencies, while others, perhaps, will remain as being peculiar to, or inseparable from, the process. As fast as these imperfections are removed so will the range of its usefulness extend; but it will have to find and make a field for itself."

The Jury have no data upon which to form an opinion as to the quantity of Bessemer metal at present produced, except so far as regards Sheffield, in which town about seventy tons are made weekly.

Mr. Bessemer (United Kingdom—6427) exhibits specimens of cannon, rollers, rails, tyres for railway wheels, and a variety of large castings and forgings made from Bessemer metal; also a collection of saws, files, edge tools, and cutlery manufactured by various firms, from steel supplied by him, but melted in crucibles, in the ordinary way, and not from ingots produced direct from pig iron by his process.

Puddled Steel.

The consumption of puddled steel in the United Kingdom, for manufacturing purposes, is very limited, the prevailing opinion being that greater regularity of temper can be obtained by carbonising the bar, either in the converting furnace or in the crucible, than can possibly be secured in the puddling furnace.

This kind of steel is, however, extensively produced on the Continent; and several specimens of it are exhibited in the Austrian, the Zollverein, and the Swedish departments, but they are not of such a character as to require any special notice here.

English Steel-Iron.

Great improvement has been made in the manufacture of English steel-irons, by mixing foreign with English pig.

These irons are now generally used for purposes, for which fifteen years ago nothing but common Swedish brands would have been deemed suitable.

The production of this kind of iron has greatly increased, not only in various parts of the United Kingdom, but also in foreign countries; and in Sheffield, where its manufacture was introduced only a few days ago, it has now become an important branch of trade.

Old Method of Making Cast Steel.

The old method of making cast steel, first introduced by the late Mr. Huntsman, continues steadily to progress.

By this process cast steel is produced, combining in the highest degree hardness with toughness and elasticity, capable of being welded, of receiving a brilliant polish, and of sustaining the finest cutting edge. It is therefore specially suited for the manufacture of good tools, whether they be the chipping chisel, the turning and planing tool, the file, or the taps and dies required in the machine shop, the saw and axe of the backwoodsman, the various implements of the agriculturist, the blade of the razor or lancet, the delicate spring of the watch, or the useful pen and needle; in a word, the use of this metal is now so general that there is scarcely any branch of industry that can entirely dispense with it.

The number of converting furnaces at present erected in Sheffield and its immediate neighbourhood is 205, being an increase of 60 since 1851. These new furnaces are, however, larger by at least twenty-five per cent. than the old ones, which would make the increase equal to seventy-five of the old size, or about fifty-two and a-half per cent.

If worked regularly, making due allowances for repairs and other unavoidable hindrances, these 205 furnaces would produce annually 78,720 tons of blistered steel.

The present number of melting furnaces, or holes, as they are usually termed in this town and neighbourhood, is 2,437, being an increase since 1851 of 1,104, or about eighty-two and a half per cent.

These furnaces, if worked regularly, making due allowances for repairs and holidays, would produce 60,772 tons of cast steel in the ingot; and if from this quantity be deducted fifteen per cent. for waste, ends, and parings, caused in the processes of forging, tilting, rolling, and paring, there would remain 51,656 tons of saleable cast steel as the annual produce.

The recent application of this metal to crinoline has, no doubt, given a great impetus to the trade. It is computed that there are at the present time from 130 to 150 tons consumed weekly in the manufacture of this still favourite and fashionable part of female attire.

The quantity used in the manufacture of that useful and now necessary article, the steel pen, is estimated at about sixteen tons a week, being an increase since 1851 of about forty per cent.

It is worthy of remark that in this trade there have been no unions, known as "trade-unions," and yet the workmen have been well paid for their labour, and disputes between them and their employers very few. The trade is principally recruited with workmen from the agricultural districts, who usually commence with 18s. a week wages, and many are advanced, after a few years' service, to from 24s. to 36s. a week according to their aptitude and ability.

The above-mentioned rates of wages apply to workmen employed in the converting and melting furnaces; those engaged in the tilts, forges, and rolling mills will earn from 24s. to 66s. a week.

Next to the steel trade the greatest progress and improvement appear to have been made in those branches of manufacture which have, as it were, been created and are still supported by the wants of the vast railway and steam navigation systems, viz., the manufacture of railway springs, buffers, steel rails, wheels, tires, and a variety of other large steel forgings and castings required for constructive purposes.

Sheffield has now become the principal seat in the United Kingdom for the manufacture of these articles.

Messrs. Thomas Turton and Sons (6,467), Charles Cammell and Co. (6,432), and John Brown and Co. (6,430), exhibit large and varied assortments of them, which for excellence of quality and workmanship cannot be too highly commended.

They are also made extensively in France, the Zollverein, and other foreign countries.

The Jury have pleasure in referring to the large, excellent, and useful contributions of Messrs. Naylor, Vickers, and Co., Don Works Sheffield (6,448), consisting of cast-steel bells, cast-steel railway whels and tires, crossings, and large cast-steel forgings.

The manufacture of bells, tires, wheels, and crossings from cast steel, is a recent application of this metal, and great credit is due to the proprietors of the Don Works for introducing so important a branch of trade into this country.

The Jury are informed that the processes adopted at the Don Works are the same as those carried on by M. Krupp at Essen, and the Bochum Mining and Cast Steel Manufacturing Company at Arnburg.

Although the contributions of M. F. Krupp, of Essen (Prussia—1,308), are not in Class XXXII., but in Class VIII., the Jury consider them of so important a character as to deserve special notice at their hands. The remarkable features of this collection are the enormous size of the castings and forgings, and their perfect soundness and uniformity of temper as shown by the fractures. In this respect M. Krupp is at present far in advance of other manufacturers—one block of steel in this collection is of the extraordinary weight of 40,000 lbs. M. Krupp exhibits specimens of cannon, and rollers beautifully finished, also cast-steel railway wheels, tires, and a variety of other large steel forgings.

The jury refer also with pleasure to the productions of the Bochum Mining and Cast Steel Manufacturing Company of Arnburg (Prussia, 1,253), although appearing in Class V. This company exhibits a large cast-steel bell weighing 22,300 lbs.; cast-steel wheels and tires.

The processes of manufacture at Arnburg are the same as those at Essen.

Pen, Needle, and Fish-hook Trades.

The progress in the metallic pen, the needle,

and fish-hook trades since 1851 has been considerable, not only as regards the quantity produced, but also in the style, finish, and quality of the articles.

The Jury have not been able to ascertain accurately the percentage of increase of production; but from information received from persons competent to give a correct opinion on the subject, infer that it has been at least from 30 to 40 per cent. These trades still suffer greatly from the dishonest practice of foreign manufacturers, especially Prussians, impressing the marks and labels of the best English makers on their cheap and inferior articles. The Jury noticed that nearly all the descriptive labels on the packages of needles exhibited by Prussian manufacturers were in English.

The contributions from these trades number, viz.:—

	Pens.	Needles and Fish-hooks.
United Kingdom	10	16
France	4	—
Zollverein	—	6

Considerable taste has been shown by the exhibitors in the arrangement of the cases, so as to display in an advantageous manner the great variety of shapes and style of finish of the numerous articles within them.

ON THE WEAR AND TEAR OF AGRICULTURAL STEAM-ENGINES AND THRESHING MACHINES, WHETHER FIXED OR PORTABLE.*

(Concluded from page 290.)

BY HENRY EVERSHED.

DEPRECIATION OF THRESHING-MACHINES.

WE have seen the *portable single-blast machines* working well at eight or ten years old: to be sure some of them had been nearly re-constructed and paid for twice over in adopting the various improvements introduced since they were first built in the early days of portable thresing-machines. Considering that all these improvements have brought them much nearer perfection, we may safely allot to the single-blast machines a duration of ten years, and to the double-blast that of eight years. We shall suppose them to be worth £10 to £20, according to size and first cost, at the end of the time. We refer to such machines as are used two days a week, and at the same time well managed. With less work they would of course last longer. It would be a very large farm to find work for a machine even once a week; but in common practice, when not fully employed at home, they are sent out to earn some part of the purchase money; and this is obviously good policy in the case of a machine liable to be superseded before it is worn out.

Fixed barn-works are used far less often, since it is likely that not more than 2,000 quarters of corn will be brought to the same spot in one year, and generally much less; yet even this quantity would only employ the machine once a week: the *repairs* will therefore be far less considerable. The wear and tear of a machine firmly fixed and quite level are comparatively small; since it is always in the dry, the charge for the waterproof cloth may be omitted, and that for the driving-strap reduced to 15s. Any heavy expense in repairs or renewal of the parts, such as the drum or concave, ought not to occur for many years after erection; and the usual wearing of brasses, and straps, and other small items of expense, ought not to exceed £3 a year for a term of 14 years.

We make the following extract from a letter of Mr. John Sowerby, jun., of Beelsbey, who has two barn-works—erected in January, 1856, and November, 1857—which thresh the growth of 400 acres of corn a-year:—"The barn-works have cost for repairs, about £3 9s. 6d. for one of them until July, 1857, and for both barn-works, from that time until December 31, 1861, about £9 6s. 5d., besides 14s. 6d. for a set of knives for the barley-awner. They were not looked over last summer, but are in good working order." This is only £1 3s. 9d. per annum for *each*, for four years.

There is, however, a liability in this, as in the portable machine, to outlay in introducing modern improvements into the working parts; with this in view the machine should be made as simple as possible, and the dressing apparatus should be separate

As a basis for calculations in our attempt to estimate the exact amount of depreciation, we will suppose the fixed machine to be worth £10 to £30 at fourteen years old; it will probably be worth more, but the valuation ought, on principle, to be low, for it will be remembered that our charge of £3 a year for repairs has not provided for effecting any heavy item of renewal or improvement.

Table showing Amount of Repairs and Depreciation for Portable Threshing-Machines—Single Blast.

Horse Power.	Price	Suppos'd Value in 10 Years.	Amount of Depreciation and Interest per Annum for 10 Years.	Amount of Repairs per Annum for 10 Years.
	£	£	£ s. £ s. £ s.	£ s.
4	85	10	9 14 + 0 10 = 10 4	8 0
7	100	10	11 12 + 0 10 = 12 2	9 0

Repairs, &c., for Portable Thresing-Machines—Double and Treble Blast.

5	95	10	13 0 + 0 10 = 13 10	10 0
7	110	15	14 12 + 0 15 = 15 7	12 0
8	120	20	15 4 + 1 0 = 16 4	14 0

For Fixed Threshing-Machine to finish the Grain for Market.

Horse Power.	Price.	Suppos'd Value in 14 Years.	Amount of Depreciation and Interest per Annum for 14 Years.	Amount of Repairs per Annum for 10 Years.
	£	£	£ s. £ s. £ s.	£ s.
7	120	20	10 2 + 1 0 = 11 2	3 0

Repairs, &c., of Fixed Threshing-Machine with separate Dressing Apparatus and Elevators.

8	140	30	11 2 + 1 10 = 12 12	4 0

For Fixed Threshing Machine—Single-Blast.

5	80	10	7 0 + 0 10 = 7 10	2 10

COST OF THRESHING.*

Since the cost of maintaining a seven-horse power portable engine amounts to £35 12s., and of a seven-horse power single-blast machine—including £3 a-year for driving-strap and water-proof cover—to £24 2s., the number of days each is used in a year must be ascertained, in order that the proper proportion may be charged to each day's work. Our calculations have been made on the supposition that the threshing is confined to the work of one large farm; if the engine is let out, a different estimate must be made.

The following are the average quantities of corn threshed in a day of ten hours by a seven-horse power portable engine and single-blast machine, in use three days a-week on an average, in a good district in Essex.

The owner of this machine found that an eight-horse power engine and finishing machine averaged about the same amount of work as a seven-horse power single-blast machine, for the years 1860 and 1861; the average quantity of coal, costing 18s. per ton, used for the former was 8¾ cwt., and for the latter 7½ cwt.

EXPENSE OF A DAY'S THRESHING BY SINGLE-BLAST MACHINE, ESTIMATING THE ENGINE TO BE USED ON THE FARM ONCE A-WEEK, AND THE MACHINE THIRTY DAYS A-YEAR.

Crop of 1860 (a wet harvest):—

Reaped wheat,	46	quarters, at	1s. 9d.	per quarter.
Mown ditto	38	,,	2s. 1½d.	,,
Barley	33	,,	2s. 5¼d.	,,
Oats	50	,,	1s. 7d.	,,

Crop of 1861 (a fine harvest and average crop):—

Reaped wheat,	52	quarters, at	1s. 6½d.	per quarter.
Mown ditto	46	,,	1s. 9d.	,,
Barley	40	,,	2s. 0d.	,,
Oats	55	,,	1s. 5½d.	,,

DETAILS OF COST BY SINGLE-BLAST MACHINE WHEN WORKED IN THE FIELD, AND STRAW LEFT STACKED ON THE SPOT.

	s. d.	£ s. d.
1 engineer	3 6	
1 feeder	3 6	
2 to supply, &c.	3 0	
3 on stack	6 0	
1 to shake straw	2 0	
1 to pitch ditto	2 0	
3 to stack ditto	6 0

		£2 17 6

To these average results it may be interesting to add the particulars of two trials, made by the writer on January 21 and 22, 1862, with a single-blast machine, made in 1854, driven by an eight-horse power engine, made in 1856, by Messrs. Clayton and Shuttlework. On the second day we threshed of mown wheat, 10 quarters; of

* From the Journal of the Royal Agricultural Society.

* It may be interesting to note the latest prices for threshing by flail, on a largo farm in Surrey:—

Prices for 1860.			Prices for 1861.		
Wheat	4 0	per quarter.		4 0	per quarter.
Barley	3 0	,,		2 9	,,
Oats	1 10	,,		1 8	,,
Peas	2 3	,,		2 3	,,

My informant states "the price for labour has risen considerably in this neighbourhood during the last few years. The price for wheat threshed would, a few years since, have been 6d. or 8d. per quarter less than in the last two years. The present labourers want to work less and to earn more than those of the last generation.

This sounds like the knell of one of the departing customs of our fathers.

* Forty-four quarters was the maximum in one day. To each of these estimates we must add 4½d. per quarter for incidental expenses, and, in the case of single-blast machines, 2½d. per quarter for dressing twice and measuring. In practice, it is usual to dress once and re-measure, even after the so-called finishing-machine, partly to get a uniform sample, and partly to improve the dressing and obtain accurate measure.

straw, 61 cwt.; of cavings, 4¾ cwt.; of chaff, 7 cwt. per hour. The crop was not heavy, only about 4 quarters per acre. This gives 24 acres threshed in ten hours, yielding 100 quarters of wheat, 30½ tons of straw, 5 tons 7 cwt. cavings and chaff. This was a larger proportion of cavings and chaff than that obtained at other trials.

The number of men and lads employed was 19; and they had a short distance to carry the straw; 12 cwt. of steam coal w e used.

On the first day we thresh d 8 quarters of barley an hour, having five m n on the stack and two on the stage to supply the feeder, and the machine could certainly have borne faster feeding if the men on the stack could have delivered the straw faster. The corn, in a day of ten hours, would have amounted to 80 quarters, the straw and cavings to 23½ tons, and the chaff to 1 ton 1 cwt. The crop was only 5 quarters per acre, and the straw long and coarse.

The number of hands employed, including two lads, was twenty-one. The costs, with these maximum results, adopting our former calculation, would be 1s. per quarter for the barley and 9¼d. per quarter for the wheat.

But we have not yet stated the whole of the expenses of threshing in the field, which include the cost of removal, of clearing up, and of thatching the stack; and for purposes of comparison with threshing by flail we ought also to bring the straw to the barn or yard. Removals may probably take five horses and one man a quarter of a day, on the average, every time the machine is used, and cost, say 3s. 4d.; clearing up, one horse and a boy, 3s. 4d.; thatching, at 6d. per square, 4s.; for 15 tons of straw, a fair day's threshing, carting home the same quantity of straw, 7s. 6d. These expenses of course vary with the site of the stack, the convenience or otherwise of storing, and the care taken of the straw, and the attention or neglect of neatness in the stack-yard; on the whole, we believe them to be no more than the average. It will be seen that they add 18s. 2d. to the expenses of a day's threshing, or 4½ per qr. at 48 qrs. per day, to the cost of separating the grain from the straw and chaff and of carrying each to the barn.

Portable straw elevators may be referred to as a means of assistance in certain cases, though their price and cost of removal precludes their being used with economy where labourers can be obtained at 2s. per day. The cost of one to deliver straight is about £50, or to deliver at any angle, about £60, varrying according to length. Their sale has been almost entirely confined to districts where labourers are scarce.

THRESHING BY FIXED MACHINE, EIGHT-HORSE POWER.

	£	s.	d.
Depreciation and repair of engine supposing it to be used once a week ...	0	7	1
Do. do. Machine 30 days a year ...	0	9	4
Oil, and 8 cwt. of coal	0	9	0
Interest on building (proportion of £9)	0	3	7
Do. on elevation and shafting, £50 ...	0	3	0
Labour (as previously detailed)	1	9	6
	£3	1	6

The last item includes eight horses to cart the crop from the stack, and eleven men and boys. The straw is carried into the straw-rick by elevators consisting of an endless web, which may be put up at the expense of from £10 to £20, according to length.

On farms where much straw is used for feeding, the expensive process of cutting it into chaff may with very great economy be carried on at the time of threshing. Ten tons of chaff may be cut in a day, and supposing from twelve to fifteen tons of straw to be threshed, the remainder is stored elsewhere. The cost of chaff-cutting by steam power has been recently estimated at 6s. per ton, which we consider a fair average price; but in this case it is cut at only the cost of the extra coal, and of the two men to "yelm" the straw and feed the machine, the straw being brought to it by the web, and the chaff either falling into the store-room or being taken there by the exhaust tube. To enable a smaller engine to do this double work the threshing-machine may be fed slower than usual with economy. It takes four or five horse-power to work the chaff-machine, but the so-called eight or ten horse-power engines give at least half as much power again as their name implies.

Mr. Jonas's practice, when both cutting chaff and threshing, is to apply the power to a strong extra shaft fitted to the front of the threshing-machine; from two pulleys affixed to this shaft both the drum and the chaff-machine are driven: in this manner no extra strain is put upon the drum-shaft. By these means the whole of the cost of stacking, and afterwards bringing the straw to the chaff-engine, is saved. It is thus cut and stored at very little more expense than the cost of a few extra cwts. of coal for the engine. The credit of these really practical and economical arrangements is due to Mr. Maynard of Whittlesford. Mr. Jonas showed us a barn in which he was in the habit of storing the produce of nearly 100 acres of straw cut into chaff, and well trodden; and since the chaff, when well salted and trodden in a dry place, heats slightly and improves with keeping, this method of storing may be recommended as a means of getting rid of the accumulation of the straw about the premises at certain seasons of the year.

It may be useful to know how much chaff, well trodden in, will go into a certain space: one of own our chaff-houses, in which we have tried the experiment, is 35 ft. long, 15½ ft.wide, and 11 ft. high. Its content is therefore 5,967 cubic feet, and it holds 19½ tons of wheat-straw chaff, = 306 cubic feet per ton. Eight acres of mown wheat-straw, of last harvest, rather a heavy crop, weighed exactly 12 tons, and occupied a space, when trussed and stored in the straw-rick, of rather more than 12,000 cubic feet. In round numbers, trussed wheat-straw occupies a space of 1,000 cubic feet per ton:—more, if stored loose and untrodden; less, if well trodden with horses: cut into short chaff and well trodden, it takes less than one-third of that space.

The combined arrangements for threshing and cutting chaff at the same time, a e becoming all the more practicable from the increased power of the engines in common use. In 1851 the average of the portable engines made by Messrs. Clayton and Shuttleworth was five-horse power, and in 1855 nearly seven-horse power. And as the question of steam-ploughing becomes more and more one of practical utility and economy, there is no doubt that the larger engines will be the most desirable upon farms.

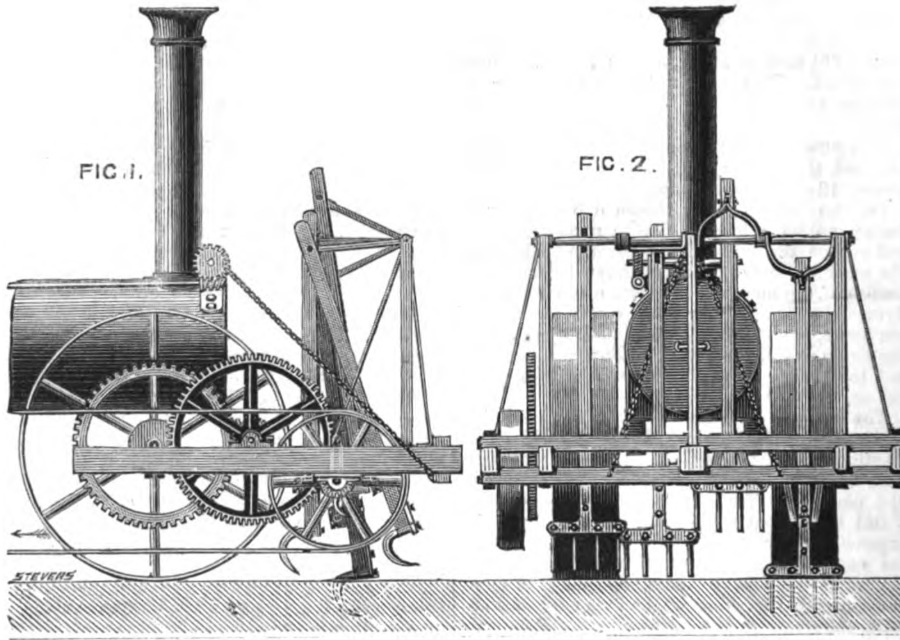
SIR DAVID BREWSTER ON THE PATENT LAWS.

LAST week Sir David Brewster delivered an introductory address at the opening of the Edinburgh University, from which we extract the following interesting passages on the above subjects:—

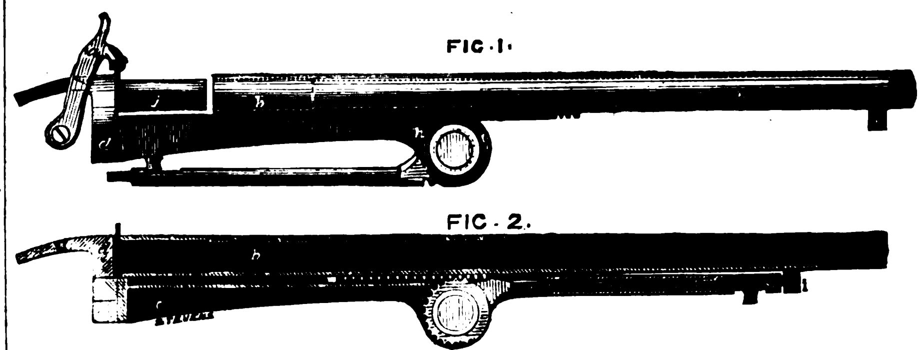
Among the subjects which occasionally arrest and agitate the public mind, there are few which immediately affect the position and interests of educated men. Such questions, however, have occurred, but they have generally been settled by the united wisdom of the Government and the Legislature, without any of those appeals to popular or party clamour under which great measures have been often abandoned or impaired. A question of this kind, however, has unexpectedly arisen respecting the amount of protection which inventors should receive from the Legislature: and there is, doubtless, no subject more important to educated men, whether their education has been completed in the school, the workshop, or the university. You are all aware that the author of any literary work, however small be its dimensions, and however frivolous its subject, enjoys, by the laws of England, the sole right of publishing it for twenty-eight years, and during the rest of his life. The only tax exacted by the law, and that only for the benefit of the public, is the presentation of five copies to the principal libraries in the kingdom. The artist, the engineer, the draftsman, the geographer, the hydrographer, and the sculptor, enjoy the same valuable right; and so complete is the protection afforded by the law that piracy is almost unknown; and works thus secured constitute a property, which can be as safely transferred as land or money in the funds. It is otherwise, however, with the inventor of new machines, new instruments, and new processes in the fine and useful arts. While the author can instantly dispose of his work, or draw the profits which it may yield, the inventor must devote himself to the developement and practical application of his invention. When his arrangements are complete, he applies for a patent, and he receives a right to use his invention for fourteen years by paying fees and expenses which, half a century ago, amounted in many cases to £400 or £500. The right thus obtained was entirely illusory. His parchment, indeed, bore the Great Seal of England, but the patent could be reused, and the price of it forfeited, either from want of complete originality in the invention, or from frivolous defects in his own description of it. In this state of the Patent Law, injurious to the interests of the public, and ruinous to inventors, our distinguished Chancellor, Lord Brougham, directed his attention to the subject, and carried two bills through Parliament which reduced the price of patents, and removed many of the more obnoxious provisions of the former law. These improvements were generally acceptable, and though inventors were still dissatisfied with the large sum of about £150 or £200 which they had to pay, and with the imperfect protection which their pat nt secured, they nevertheless submitted to the operation of the law, in the hope that future legislation might improve it. Under these circumstances, men of science, and inventors of all classes, were startled with a proposal made by a distinguished engineer, that the Patent Law should be repealed, and that there should be something like free trade in inventions. In addressing an assembly of civil engineers at Sheffield, Sir William Armstrong stated "that the dauntless spirit which, in matters of commerce, had led this country to cast off the trammels of protection, had resulted in augmented prosperity to the nation, showing the injurious tendencies of class legislation when opposed to general freedom of action;" and he expressed a hope "that the same bold and enlightened policy might be extended, in some degree at least, to matters of invention. For his own part, he was inclined to think that the prestige of successful invention would, as a rule, bring with it sufficient reward, and that protection might be entirely dispensed with." Under the free trade of the present day, thus highly and justly appreciated, we receive the corn and the wines of one country in return for the iron and the coal of another; but it exceeds our comprehension how there can be free-trade between two parties, one of which is the small class of discoverors and inventors, and the other the whole mass of society, who are not inventors at all, and who, with all the influence of numbers, wealth, and position, would instantly appropriate and turn to profit every discovery in science that had a practical bearing, and every mechanical idea that could be embodied in an instrument or a machine. Between such parties as these there can be no interchange of ideas, and no reciprocity of interests; and as there can be no dealings between them, there can be no freedom of trade in any sense analagous to that great commercial doctrine to which reference has been made. But even under the present Patent Laws, as they exist in every part of the Old and New World, there is already something approaching to freedom of trade. Every foreigner can obtain a patent in England on the same terms as an Englishman, and an Englishman enjoys a similar right in return. The producers of ideas, therefore, are in every country in the same relative position nearly as the producers of those commodities which are interchanged under free-trade—the non-producers of ideas and the non-producers of commodities deriving alalogous advantages under the law—the one from the importation of useful inventions, and the other

from the importation of the necessaries and luxuries of life. There is still, however, another variety of free-trade in inventions which, we think, is the only one that deserves the name. Were a patent right granted at the cost merely of its registration to every applicant, and continued with equal security during the same period as copyright, every new idea—every scheme of ingenuity or adventure—would be brought before the public, and elaborated for the use of man. Such a scheme may be expected in some future age, when statesmen may have learned to face problems before which they now quail, and appreciate interests to which they are now insensible. Regarding all intellectual rights as equal, and as sacred as any other species of property, it is not easy to understand why they should not be placed under the same ægis. *Esto perpetuum* is the brand which God and reason have stamped upon whatever man's genius or man's industry has created for the good of man. If the rich or the barren soil which conquest has wrested from the savage, or industry won from nature, is protected with as much care as the life of its owner, why should we not equally protect the rights achieved by genius, whether in the useful arts it creates for humanity new powers and products, or bless our species with the divine creations of poetry, or eloquence, or art? If James Watt has bequeathed to us mechanism to bring water from its earth-bosomed springs, or iron from its stony bed, or coal from its fossil grave; if Milton has sung the loss and recovery of Paradise in strains moral, religious, and sublime, why should not the philosopher and the poet enjoy the same right of property as a landlord who reclaims a moss, gives verdure to a heath, or makes the yellow grain wave over a beach of sand? I should hardly have been justified by the speech of Sir W. Armstrong in taking alarm at the revolutionary opinions which he has maintained; but it is well known that a Cabinet Minister of high influence has given utterance to the same views, and a Committee of Parliament has been appointed to report on the subject of patents in all their relations. The British Association was the first public body that took alarm at the new doctrines, and boldly denounced them; and an inventor's institute has been formed in the metropolis to resist, by every legal means, any measure of spoliation that the Government may be induced to support. I have brought this subject under your notice in the belief that every educated man has a substantial interest in obtaining a due protection to inventors, and in the hope that in your debating societies you may regard this subject as worthy of discussion.

MORRIS'S MACHINE FOR CULTIVATING LAND.



PARFREY'S BREECH-LOADING FIREARMS.



MORRIS'S MACHINE FOR CULTIVATING LAND.

The above engravings represent a machine for breaking-up and cultivating land, which has been recently patented by Mr. J. Morris, of Essington, Stafford. The machine is fitted with a series of forks or prongs, having an advancing horizontal motion, which are made to enter the land to the depth of several inches, and afterwards rise therefrom, ths said forks or prongs performing a nearly circular motion in a vertical plane. The machine is constructed in the following manner:—At the back of a steam locomotive engine a horizontal shaft is supported, to which a rapid rotary motion is given by the motion of the engine of the locomotive. The shaft is at right angles to the path of the engine. A series of excentrics are fixed on the shaft, and to the under side of clips encircling the eccentrics the forks or series of prongs are fixed. A vertical rod is fixed to the top of each of the clips of the eccentrics, and each of the rods is jointed to a horizontal guide rod turning upon a joint at the back of the engine. By the rotation of the shaft carrying the eccentrics the forks or prongs are made to perform a nearly circular motion in a vertical plane. This motion, combined with the advancing motion of the locomotive, causes the forks or prongs to enter the land, performing a nearly semi-circular motion therein, and rising therefrom to re-enter it a short distance in advance of the point at which they last entered it. The eccentrics are so arranged on the shaft as to make the forks or prongs enter the ground in succession, and thereby to equalise the resistance. The prongs are of a curved figure.

PARFREY'S BREECH-LOADING FIRE-ARMS.

Mr. J. Parfrey, of Upper Belgrave-place, Pimlico, has patented an improved breech-loading firearm, which consists in applying to the ordinary false breech of a gun a strong und light sliding bar, on which the barrels are arranged to slide longitudinally forwards sufficiently to admit of the introduction of cartridges at the breech ends of the barrels, which are, by a forward sliding action, presented open, and which, when loaded, are slid back into close contact with the false breech, a small groove or notch being left in each barrel, in order to admit the projection of the detonating pin of the cartridge. In order to slide the barrels forward and backward with facility, and obtain power enough to make a close joint at the breech, a small lever or handle is employed, with a sector or pinion and a rack, the one attached to the barrels, the other to the sliding bar; when the barrels slide home, this lever is brought up under the barrels, and secured by a catch pin. These improvements are applicable to firearms having one or more barrels, which may be joined together and actuated by one handle.

Fig. 1 is an outside edge view of part of a double-barrelled gun with the stock removed, shewing the breech-piece and slide, the handle and sector for actuating the barrels, and the barrels which, having been discharged and slid forwards, a cartridge is shewn extracted ready to be released by the lifting of the hammer. Fig. 2 is a section through the centre of the breech-piece, slide, and one barrel, shewing the barrels brought home to the breech by the reversal of the handle below, which is secured by the spring pin at the end locking into the staple under the barrels. *a* is the hammer; *b*, *b*, the barrels chambered out so at to receive the cartridges, and having grooves to admit the detonating pins; *c*, a slide with V-shaped edges, strengthened by webs underneath, to which the barrels are fitted; this slide may be formed in one piece with, or be securely screwed, as shewn, or otherwise attached to the breech-piece *d*, and to the stock by screws, *s*; *e* is a lever or handle, the boss at the end of which is cut, as a sector, into teeth on its outer edge, so as to work into the teeth *f* attached to the under side of the barrels; the groove in the slide admits of the passage of these teeth; the handle *e* moves on the hollow pin or thimble *g* fitted to the cheeks, *h*, of the slide, and secured by a nut, so as to give facility for removal when it is desired to separate the barrels from the stock; by lifting the hammer *a* the spent cartridge *j* falls aside, then fresh cartridges being inserted into the open ends of the barrels,* the handle *e* is brought down from the position shewn at Fig. 1, and up again, as at Fig. 2.

M. Mathieu (de la Drôme) has addressed a letter to the Paris journals, in which, after alluding to the means now acted on in England for prognosticating storms some hours, and even a day beforehand, he declares that he will, whenever it may be wished, furnish to France and to all the countries of Europe, the means of foreseeing all atmospheric phenomena, not one day, but 50 years in advance.

H. SMITH'S FOUNDRY LADLE APPARATUS.

FIG. 1.

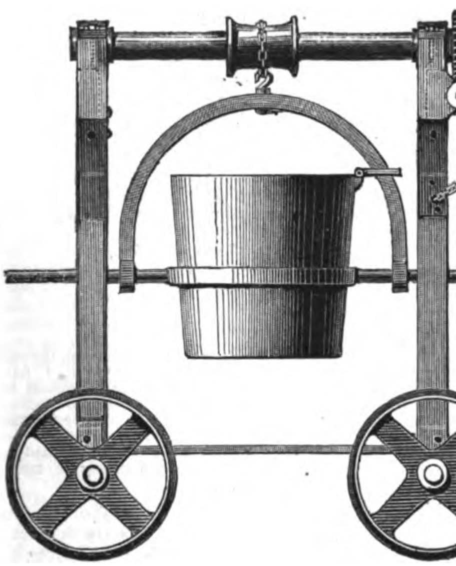


FIG. 2.

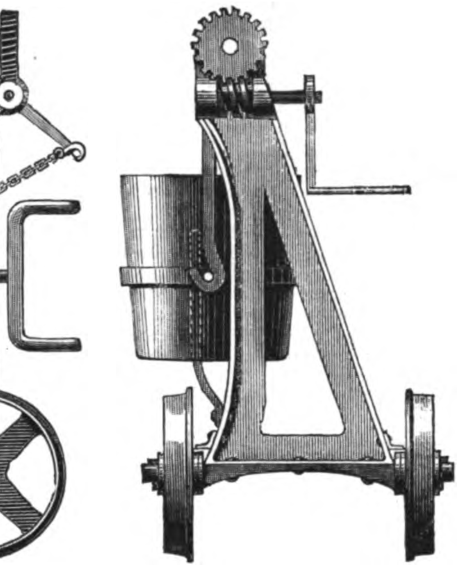

SMITH'S FOUNDRY LADLE APPARATUS.

THIS invention, patented by Mr. H. Smith, of the Teesdale Iron Works, Stockton-on-Tees, has for its object improvements in apparatus used when casting iron or other metal. For this purpose a carriage or truck is used with upright end frames suitable for receiving a ladle between them. At the upper part of these end frames there are bearings for an axis, on which axis there is fixed a barrel, on which is wound a chain to which the ladle is suspended, as illustrated in the above engravings. The axis is arranged nearer to one side of the carriage than the other by preference, but it can be placed in the centre if required, and the end framings are strongly braced or connected together. On the axis is fixed a screw or worm wheel, which receives motion from a screw or worm on a suitable axis, on which is fixed a handle or hand wheel, by which motion is given to the axis of the screw or worm, and consequently to the barrel, in order to raise or lower the ladle, or it may be raised or lowered by gearing or rachet wheel and lever. To facilitate the tilting of the ladle, the tilting bar is received into hooks or bearings at the two ends of the arched frame or bar which is suspended by the chain on the barrel. The four wheels of the truck, or carriage, are suitable for running on a rail or tramway laid down between the cupola or other melting furnace and the place where the moulds are situated.

THE DOUBLE SCREW PROPELLER— THE FLORA.

ON Friday last the "Flora," with her double screw propeller, enjoyed her trial trip on the river between Tilbury and Mouse Light.

The application of double screws under the quarters of a vessel is neither new in theory nor in practice. Some years since Captain Carpenter applied them, under the sanction of the then Lords of the Admiralty, to a pinnace under his command. The Americans have for years past used double screws in some of their large river steamers, and some of their iron ships recently built are also fitted with them. Commander Symmonds, R.N., in an able paper read by him at a meeting of the United Service Institution, and since published, satisfactorily pointed out the many advantages to be derived by this application of the screw, and laid before the meeting draughts and models of non-fouling screws, worked by separate engines, invented by himself and Mr. Roberts.

Mr. Dudgeon, however, has been the first to give us a practical illustration of the immense advantages possessed by two screw propellers over a single one. The "Flora," of 400 tons, double screw propeller, was built at Blackwall from designs by that gentleman. At the trial on Friday last the "Flora" left Tilbury-wharf, having on board Mr. Dinen, R.N., Admiralty Inspector of Steam Machinery; Commander Symmonds, R.N.; Captain Selwyn, Captain Crookshank, Mr. Dudgeon, Mr. W. Dudgeon, and a select party of officers in the naval service and mercantile marine, and many well-known yachtsmen; also, several gentlemen connected with Her Majesty's dockyards, amongst whom were some connected with the Swedish and Russian marine.

The dimensions of the "Flora" are as follow:—Length in load line, 150 ft.; beam, 22 ft. 6 in.; depth in hold, 13 ft. 6 in.; nominal horse-power, 120; indicated horse-power, 400; two screws of three blades each, 7 ft. in diameter, and having a pitch of 14 ft. 6 in. On the day of trial she drew 7 ft. water aft and 5 ft. 5 in. forward. Her displacement was 350 tons, and the area of immersed midships section 130 square feet. She is rigged as a fore and aft polacca-masted schooner; her masts fitted with joints near the deck, so that they can be lowered down should occasion require it; she is also fitted with a telescope funnel. Immediately after leaving Tilbury-wharf, her commander put her obedience to the helm to a severe test by steering a course in the form of the letter S through a fleet of shipping that lay at anchor off Gravesend: and the manner in which she steered completely set at rest any doubts that might have existed under this head. She then proceeded at moderate speed to the Nore Light, working at 15 lb. pressure, at a speed to the vessel of 10·6 knots, of the screw 14·5, with two knots of flood tide against her, and an estimated slip of two knots—making an average of 12 knots an hour. She was abreast of the Nore at 1h. 55m. 25s., just at high water, and then proceeded on her trial to the Mouse Light-vessel, 7½ nautical miles' distant. In the middle of the trial she was working at 18 lb. pressure, and the screws making 106 revolutions per minute; her engines, also made by Mr. Dudgeon, worked well. The Mouse Light was reached at 2h. 27m. 6s., exactly in 31 minutes 43 seconds. She left the Mouse Light for the Nore at 2h. 29m. 28s., and reached the latter at 3h. 18m. 40s.; she was 15 minutes detained on this passage by the port engine bearing getting heated, which would leave her passage up, against the first of ebb, at 34 minutes. After this successful trial trip we may soon expect to hear more of double screw steamers worked by double engines.

It has been sometimes observed that coke has ignited spontaneously after being, seemingly, completely extinguished by water. This phenomenon has been explained on the supposition that the coke had been originally charged with sulphate of iron, and being imperfectly extinguished, had been heaped up in places where the air was stagnant. Chemical combinations of sulphur and iron have a strong affinity for oxygen in such a case, and give out sufficient heat to bring on ignition throughout the whole mass. The lignites of Germany, which often contain iron pyrites, are also subject to this occurrence, particularly when the slack coal is carelessly left in the workings of the mine. It may be prevented by careful ventilation.

HUNTER'S IMPROVEMENTS IN ANCHORS.

THE accompanying engravings represent an improved anchor recently patented by Mr. S. Hunter, of Grey-street, Newcastle-upon-Tyne. In this improved anchor the shank or stem is made with an oblong opening near the crown end, that end of the shank or stem being spread out in a suitable manner for having such opening formed therein. The arms of the palms are of a bent or curved form, and their ends, where they pass through the crown, are scarfed together. The outer surfaces of the ends of the arms, where they turn in the crown, are cylindrical, so as to turn freely in the opening formed in the crown. These ends of the arms are securely keyed together, and there are washers or

FIG. 2.

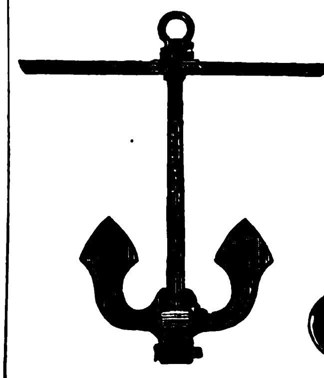

FIG. 1.

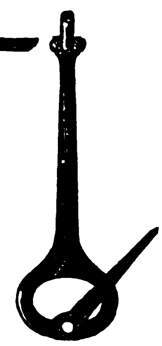

free collars between the keys and the crown of the anchor. The two arms are connected together by a bar between the palms and the ends of the arms which turn in the crown. The ends of this bar pass through the arms, and are keyed. The middle of the connecting bar is notched out in such manner as to fit the interior edge of the opening formed through the spread-out end of the stem or shank; this edge, on which the bar moves, is struck from the centre of the opening in which the arms turn in the crown of the anchor, so that when the strain comes on the palms, such strain is received by the connecting bar, which is supported by stops formed on either side of the extremities of the spread-out portion of the stem or shank. The two palms take the ground, and hold at the same time.

THE BENDING OF WOOD.*

THE applicability of bent wood for an increasing variety of purposes is both surprising and instructive. Here in this great lumber country, and in many others, it is used in all departments of business and pursuits of life wherever man and his products are known. It is as ancient as history, and is found among the artifices employed in the rudest state of barbarism. Little is known of the most ancient devices for bending wood, but the oldest patented in England has now been practiced for nearly a century, and is yet used there for some purposes. In 1813, at Woolwich Navy Yard, England, floor timbers, 16 inches square, for a man-of-war, were bent over an arc of a circle with a radius of four feet. All these devices, as well as almost all others subsequently used, restrained, in some degree, that tendency found in wood to elongate its outer curve when under the operation of bending, the same as is now claimed to be done in apparatus brought as near the state of perfection as the nature of wood and the change of position the particles undergo will admit. The organic structure of all woods of the endogenous or internal growths, and the exogenous or external growths, are similar, and possess the qualities of cohesiveness and compressibility, more or less, differing most in the degree or quantity of these two qualities, which make and determine the amount or degree of flexibility or elasticity in any wood. These qualities, with a structure that will admit any fluid

* From the "Journal of the Board of Arts and Manufactures for Upper Canada."

agency to thoroughly penetrate and soften its tissue, indicate a wood that may be made to assume any curvilinear shape required for practical use. Then only ordinary skill and judgment would be required to operate on good wood—bending successfully, without any loss occurring from breakage of the wood under the operation of bending, but where the wood has not been seasoned, or partially seasoned, a trifling loss will occur from breakage caused by the shrinkage that all woods are subject to in the process of seasoning. And in the case of unseasoned bent wood, this shrinkage acts upon the fibre of the outer curve, which is always at the point of tension, if not in an actual state of severe tension, for the reason that in deflecting any substance, but particulary wood, either with or without partial restraint, to oppose tension, the wood is acted upon by two forces, the one a crushing force that foreshortens and contracts the lesser or inner curve, with a tendency to rupture it laterally, the other a tensile force that stretches and elongates the greater or outer curve, with a tendency to fracture it transversely and lift the fibre, which is the most hurtful, and of the more frequent occurrence. These two forces are divided by a neutral line, more or less moved from either curve. When nearest the inner curve the best result is obtained, because all tension, however little, is injurious to the structure of the wood, arising from separating and drawing out the fibre, which can never be made to unite again, as in ductile and malleable substances, and because the crushing or compressing force improves the wood by forcing the fibre into the interstices or cells, and by interlacing and interlocking the fibre, the product is obtained nearly resembling the knot or knurl, which is difficult to split or cut, even when rupture is indicated.

In order to get the best result from bent wood, it is recommended that the crushing force alone be used. And this can be, if the fibre of the wood be left free to move into a new position in more than one direction from the point of bending, by beginning the curve in the middle of it when the wood is made to assume a long curve first, before taking the shorter curve of the mould, which long curvature starts the fibres throughout, and makes more, if not every particle of the wood, accessible to the influence of the softening agent already in it, and consequently more yielding to the action of the crushing force. This force should be produced and governed by fixed and immoveable restraint that should not compress the wood while in its straight form. It should also prevent end expansion, and preserve the exact length on the outer curve. This would give a product uniform in density and rigidity throughout its whole length, with the fibre undisturbed on the outer curve, to resist any tendency to change the shape produced.•The long curve gradually adapting itself to the curve of the mould, would amount to double on successive manipulation, if unrestrained; wood has been compressed into one-third of its primary bulk, with every quality improved to resist decay and wear in use. Nothing can be reasonably urged in support of the popular belief of the necessity to produce or permit tension and elongation in successful wood bending. Tension and elongation are required or permitted only in consequence of the uses of imperfect apparatus—elongation is positively indispensable in machines that bend from one end, or in one direction from the point of bending, and that press the wood against the mould with such power as to prevent all movements of the fibre, producing in advance of the point of bending a wave-like movement among the fibres of the wood, held rigidly confined and straight, until suddenly made to take the curve of the mould. The movement in advance of the bending gradually accumulates a power that resists compression thus attempted, and before the completion of the process, and in order to save the machine or the process, relaxation of restraint is required, and is followed by elongation of the wood, however small it may be. Tension acts upon the fibre, giving a product uneven throughout its whole length, and more liable to change the artificial shape. It is obvious that any augmentation of restraint during the process must give such results, and that the machinery in use for the bending of wood is far from having reached perfection. There can and will be machinery constructed to bend large timbers for marine and other structures, over any arc or curve that will not require a reduction of its bulk, by the compression of the inner curve, to less than one-half its lateral size. Past experience has shown that wood-bending machinery is most profitably employed in the production of smaller articles, for which there is an unlimited demand that will continue, because of the suitableness and superiority of bent wood for these purposes.

Iron or jointed structures are generally used on a large scale; but there can be no doubt that timber of the most imposing dimensions can be bent into many convenient forms, with considerable increase to its strength, and the appearance of the structure in which it is employed. The subject is well worthy of the attention of inventive mechanics. Steaming wood, previously to submitting it to a bending force, is now employed.

IRON WALLS AND NAVAL GUNS.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

SIR,—Another assailant of my opinion enters the field in the last MECHANICS' MAGAZINE. Mr. Cheverton, as a man of science, a logician, and a practised writer on mechanical questions, is an adversary not to be despised. I have not time this week to indite my usual letter, although there is a great deal about "Iron Walls" which I want the public to know something of. I cannot, however, by silence, leave Mr. Cheverton to suppose that, however cunning at fence he may be, he has inflicted on me any serious wounds, or even made a palpable hit.

The argument with reference to my "wood backing" *crochet*, which runs through Mr. Cheverton's letter, places me in the predicament of a physician who, having by a careful diagnosis thrown some light on the disease his patient is labouring under, is dogmatically treated as a *Charlatan*, because he is not prepared at once to apply a remedy. No account is taken of the difficulties he has to overcome in treating a difficult case, and when, like a wise man, he calls a consultation of M.D.'s, reputed more skilful than himself, one of the most eminent of the number turns round upon the earnest and anxious doctor, and twits him with uttering *truisms* in designating the complaint.

I thank my accuser for that turn, and I congratulate myself on the success of the free expression of my opinions in having drawn so able a writer into the controversy, which he will find worthy of the attention, I am glad to see, he has paid to the subject. But I wish, instead of an elaborate investigation into the precise nature of the disease, the existence and character of which he admits, he would give his aid at the consultation, to which he is called, to discover the treatment which will effect a cure. In my reply next week, I will point out some of the symptoms of the inefficiency of wood backing, and show its damaging effect on the constitution of iron plates, such as will, I hope, satisfy Mr. Cheverton that my *truisms* are *truths* which cannot be too often reiterated until England possesses "iron walls," so constructed as to be reliable national defences.

Mr. Day's communication will be noticed in my next letter. CIVILIAN.

REVOLVING BOILERS.

SIR,—In your journal of Oct. 31, I notice the description of a new marine boiler, of which it is said that its novelty "is that of making the boiler continually rotate on its axis over the furnace while at work." If your readers will refer to Galloway Hebert on the steam engine, page 376 ed. 1836, it will be seen that a boiler kept in a state of revolution over a fire was patented in 1825 by Messrs. Thompson and Barr, of Halesowen, Staffordshire. Mr. W. H. James, of London, in the year 1823, patented a revolving boiler, in which the furnace was placed inside; this may be found at page 391 of the same work. CHRONOLOGY.

JURY REPORTS.

SIR,—With reference to part of your remarks in the MECHANICS' MAGAZINE of the 7th instant, on the Report of the Jury, Class VIII., I have to state that the error of ascribing Sir William Armstrong's well-known water-pressure engines (British Catalogue, 1,785), to Messrs. Smith, Beacock, and Tannett, did not exist in that report, as it left my hands in July last.

I am, Sir, &c.,
W. J. MACQUORN RANKINE.

Glasgow, 10th November, 1862.

WORN-OUT PACKING.

SIR,—Could you or any of your readers inform me, through the medium of your valuable magazine (of which I have been a reader for many years), whether an apparatus for withdrawing the old worn-out packing from the stuffing-boxes of steam-engines, pumps, &c., is in use, or whether you think such a contrivance would be advantageous over the old system? Having invented a simple method for effecting the above purpose, I take the liberty of asking your opinion on the subject.

Apologising for thus troubling you,
I remain, &c.,
EDWIN E. HILL.

Rose-cottage, Vassall-road, Brixton, S.
Nov. 4th, 1862.

THE MERSEY BREECH LOADER.

SIR,—Not because this cannon can be fired 19 times in a minute do I specially advocate it, for other breech loaders could be fired very rapidly under special circumstances, though not so rapidly perhaps as this. But the beauty of the Mersey gun consists in what may be expressed in two words, viz. :—

1. Strength.
2. Simplicity.

Has it some latent weak point? I await an answer from Mr. Clay or the Liverpool Volunteers.

W. RIDDLE.

10th Nov.

PROPULSION OF VESSELS.

SIR,—Mr. Parker would be a most unnatural parent if he was not proud of his bantling, but he must let us know a few of his child's good qualities if he would have others think as well of it as he does.

I repeat that the small models cannot give us a good idea of the merits of his plan. Has it been tried on a large scale? I fear not (at all events with success), or we should have heard of it. Mr. Parker does not answer my question about relative speed with same fuel. As to the plan being "commercially useful," I meant to refer to *passenger* steamers, when speed is everything.

Again, too, Mr. Parker seems to consider a very peculiar stern with two guide pieces necessary. These could not be applied to a boat already built.

X. Y. Z.

November 11th, 1862.

Meetings for the Week.

TUESDAY.—INSTITUTION CIVIL ENGINEERS.—Discussion upon Mr. Crawford's paper on the Railway System of Germany, at 8 p.m.

WEDNESDAY.—GEOLOGICAL SOCIETY.—On the Cambrian and Huronian Formations, with some remarks on the Laurentian, by J. J. Bigsby, M.D. —On some Enaliosaurian Vertebræ from the Coal-measures of Nova Scotia, by O. C. Marsh, Esq., communicated by Sir C. Lyell, V.P.G.S., at 8 p.m. SOCIETY OF ARTS.—Opening Address by the Chairman, at 8 p.m.

Gossip.

The most awfully explosive shells it is possible to produce, being separate shells containing nitrogen and chlorine, enclosed in an outer shell, are now under the consideration of the War Office.

According to the *Moniteur des Inventions et Decouvertes*, Mr. A. Wattemare, Paris, informs the Societé d'Encouragement de l'Industrie Nationale that the manufacturers of the Northern States have been lately directing their attention to a new product they call "fibrelia," as a substitute for cotton. This term of "fibrelia" is a generic name applied to fibres extracted from several kinds of American plants, obtainable in Massachusetts and other parts of the world under the same latitude.

Mr. Donald M'Kay, the American ship-builder, in an account of the iron-clad ships of France, England, and the United States, says:—Of all the iron-cased ships that we (the United States) have,

the only one that might successfully cope with the large English frigates is the "Ironsides," built in Philadelphia. She is well planned, and her practical construction very well executed, but her speed is too slow to use the good points of the vessel to advantage, and the way of fastening her plates will not stand the test of a heavy cannonade; for in the experiments made in England with armour plates, similarly fastened by screw bolts screwed in from the inside, the bolts broke off short on the inside of the plate whenever a heavy shot struck the plate near such bolts.

As a remedy for the yellow fever, so fatal to engineers and mechanics, and others, in South America and the West Indies, Mr. James Bruce advises the following measures:—1. Dissolve one ounce of gum in half a pint of milk, and add the same quantity of lime water. To be divided into four doses in the twenty-four hours. 2. Or, twenty grains of chalk with ten grains of grated nutmeg, in a wine-glassful of milk or solution of gum. As a tonic in convalescence equal parts of port wine and gruel. The best disinfectant for sprinkling rooms and cabins (being nascent oxygen) is to dissolve any quantity of nitre in vinegar. The action of vinegar on nitre (as we learn from Scripture) is like music to the heart that is sad!

On the Magenta Boulevard, Paris, there is just now exhibiting an instrument, which is really a curiosity. It imitates the sound of the human voice—particularly the higher notes—almost to perfection. It was invented by Herr Faber, formerly a German professor of mathematics. The instrument has the external appearance of a woman seated; it is constructed according to the physiological principle of the larynx, which is represented by an india-rubber tube; the voice has a range of two octaves, and sings any given tune, with the tone, and force of a female voice; the form of the figure is rather defective, from the poverty of the inventor.

A letter from Turin says:—"A Venetian, named Giacomo Balbi, has published, both in France and England, a brief description of moveable forts invented by him, and capable of being used both on land and at sea. There is reason to believe that they furnished a hint for the construction of the Monitor, which caused so much excitement a few months ago. He has come to Turin, and has had long conferences with the Minister at War and the Minister of Marine, with the Ordnance Department, and the Admiralty at Genoa: and it seems that something, of which the details are not yet known, is to be constructed under his direction."

The Committee of the Mersey Docks and Harbour Board recommend the board to apply to Parliament in the next session for powers to borrow a sum of £450,000, to be applied in the construction of the new works in progress and contemplated by the board on the Liverpool side of the river, including the purchase from the Earl of Derby of the foreshore north of the dock estate, and the reclamation thereof by a sea wall.

A letter has been addressed to the Earl of Derby, the chairman of the Queen's committee, by four of the principal architects engaged in preparing designs for a national memorial of the late Prince Consort, urging an extension of the time allowed for that purpose, on the ground that the inroads on their time, arising from their ordinary professional work, render it extremely difficult, within the time previously named, to give to the designs that mature consideration which their importance demands; they therefore solicit that the time may be extended from the 1st December to the 1st January. The committee have acceded to their request, but with an intimation that no further extension of time can be allowed beyond the 1st of January.

Professor Ansted, the mineralogist, reports the discovery at St. Cuthbert's, in the Mendip Hills, about three miles from Wells, in Somersetshire, of a deposit of lead-producing *debris* of old mines and lead-washings of ancient miners, filling up the bed of a stream that flowed in former ages. This metallic slime, of exceeding richness, amounts, he says, to 600,000 tons, extends over twenty-five acres to the depth of thirty feet, and is computed to be worth half a million of money for the lead which it contains.

The efforts which have for a long time past been made to provide an electric telegraph for the fire brigade stations in the metropolis have resulted in an arrangement with the telegraph companies.

Complaints have been continually made of the inadequacy of telegraphic communication in France, while there was not a hamlet in the mountains of Switzerland which was not supplied with a telegraphic wire. The Minister of the Interior has consequently decided on establishing electric telegraphic offices in the principal town of each commune throughout the French empire.

Steel Shot.—The Select Committee of Ordnance, as well as the Iron Plate Committee, have now under consideration, the advisability of adopting "steel shot alloyed with silver" (the one 300th part). This alloy produces the very hardest description of steel, which, it is said, will penetrate any amount of iron or backing a ship can be made to carry with *vire viva*. The inventor states that steel shot, alloyed with this portion of silver, will not be more expense, as a much lighter shot will be used.

The Poonah.—On Saturday last the new screw ship intended for the service of the Peninsular and Oriental Company, was launched at the Thames Shipbuilding Works, Blackwall. The launch, which was witnessed by a large company, was most satisfactory. The "Poonah" is a splendid ship, of 2,597 tons burthen. Her length between perpendiculars is 315 ft.; length of keel for tonnage, 290 ft. 5 in.; breadth for tonnage, 41 ft.; depth of hold, 30 ft. No pains have been spared in her construction. She is alike beautiful in model and great in strength. As soon as she had brought up in the river, amid the cheers of thousands who studied the wharfs and banks, she was taken in tow and proceeded to Deptford to receive her engines, which have been constructed by Messrs Humphreys and Tennant. They contain every modern improvement for super-heating steam, surface-condensing, &c., with a view to the saving of fuel, and are of 500 horse-power.

Portable Ships' Engine Pumps.—Last week some trials and experiments took place in Woolwich Dockyard, by order of the Board of Admiralty, to test the relative merits of three rival portable ships' engine-pumps. The Commodore Superintendent, Sir F. Nicolson, Mr. Turner, and Mr. Thornton, and others were in attendance. The first engine tried was that of Mr. Roberts, of Millwall, and manufactured by Messrs. Brown, Lennox, and Co. This was a double-action pillar-pump, and was worked by four men, and afterwards by double that number, casting various jets of water by a change of hose-pipes, directed horizontally and vertically. It filled a tank containing 108 gallons of water in 2 minutes and 31 seconds, from one of the fitting basins adjoining the place of trial. The result was very satisfactory. The next trial was with Mr. Stone's, of Deptford, also a portable engine of similar dimensions, but pronounced superior in power and capacity in each of thg tests, as to distance, height, and the time consumed in filling the tank. The third engine was that of Mr. Gossage, of the Admiralty, and manufactured by Mr. Stone, which underwent the same series of trials as the two named above, and with a slight advantage over that of Mr. Roberts. At the termination of the trials an opinion was pronounced by the inspecting officers in favour of the engine supplied by Mr. Stone.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

The Abridged Specifications of Patents given below are classified, according to the subjects to which the respective inventions refer, in the following Table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved, and combined with all the advantages of a division into classes. It should be understood that these abridgements are prepared exclusively for this Magazine from official copies supplied by the Government, and are therefore the property of the Proprietors of this Magazine. Other Papers are hereby warned not to produce them without an acknowledgement:—

Steam Engines, &c., 1091, 1123, 1130.
Boilers and Furnaces, 1154.
Roads and Vehicles, including railway plant and carriages, saddlery and harness, &c., 1083, 1111, 1112, 1129, 1132, 1133.
Ships and Boats, including their fittings, 1088, 1116, 1119, 1138, 1150, 1156.
Cultivation of the Soil, including agricultural implements and machines, 1136.
Food and Beverages, including apparatus for preparing food for men and animals—*none*.
Fibrous Fabrics, including machinery for treating fibres, pulp, paper, &c., 1079, 1086, 1087, 1089, 1099, 1104, 1120, 1122, 1126, 1134, 1142, 1152.
Buildings and Building Materials, 1121, 1151.
Lighting, Heating, and Ventilating, 1021, 1139.
Furniture and Apparel, including household utensils, time-keepers, jewellery, musical instruments, &c., 1080, 1092, 1096, 1106, 1117, 1131, 1140, 1145, 1148.
Metals, including apparatus for their manufacture, 1085, 1102.
Chemistry and Photography, 1090, 1115, 1118, 1127.
Electrical Apparatus, 1095.
Warfare, 1081, 1082, 1084, 1094, 1098, 1101, 1108, 1144, 1146, 1153,
Letter-Press Printing—*none*.
Miscellaneous, 1093, 1097, 1100, 1105, 1107, 1109, 1110, 1113, 1114, 1124, 1125, 1128, 1135, 1137, 1141, 1143, 1147, 1149, 1155.

1065. F. Tolhausen. *A telegraphic dial printing apparatus.* (A communication.) Dated April 14, 1862.

This invention is not described apart from the drawings. *Patent completed.*

1066. J. Beard. *An improvement or improvements in sofa bed or sofa bedsteads.* Dated April 14, 1862.

This consists in making that part of a sofa bed or sofa bedstead called the seat or bed reversible, that is, so as to present either of its surfaces uppermost at will, one side being a sofa seat and the other a bed. *Patent abandoned.*

1067. J. M. French. *Improvements in upright pianofortes.* Dated April 14, 1862.

This consists, first, in making the bracings of upright pianofortes of tubes of wood. The bracings are situated between the wrist plank and the bent side and bottom, and have to support the pressure which the tension of the wires exert upon the said wrist plank and bent side and bottom; second, in making the sounding boards to such pianos of Swiss pine, or other wood, joined by vertical junctions, the said junctions being covered by the belly bars of the sounding boards. *Patent abandoned.*

1068. J. Darlington. *Improvements in the arrangement of marine telegraph wires and cables.* Dated April 14, 1862.

Instead of laying telegraphic wires or cables so as to rest on the bed of the sea, the inventor proposes to arrange these in such a manner as to lie only a portion of their length on the bottom, and in deep water to suspend them by means of floating or partially submerged buoys, set at such distances as may be found necessary; also at certain distances to stay or anchor such wires or cables by means of suitable appliances. He further proposes to connect with such wires or cables, wherever it may be found desirable, floating telegraphic stations for the receipt and transmission of messages. *Patent abandoned.*

1069. J. K. Hampshire. *A safety cage, with disconnecting catch, to prevent accidents in the working of coal or other mines arising from the over-winding or breaking of the ropes or other parts used for hoisting purposes.* Dated April 14, 1862.

This invention is not described apart from the drawings. *Patent completed.*

1070. J. Dargue. *Improvements in machinery for preparing and combing wool and other fibrous materials.* Dated April 14, 1862.

This relates, first, to the collars of the screws, which force the heckles through the fibrous material, and consists in making the parts of the screw which revolve in the bearings conical, the bearings being suitably formed to receive such conical parts of the screws. The invention consists, second, in a method of raising and lowering the fallers or heckles in what are known as screw gills. The invention consists, third, in a peculiar method of grooving the bearings and necks of machinery used for preparing, combing, and drawing fibrous material, so that the oil may be equally distributed over such surfaces. This is accomplished by cutting right and left-handed spiral grooves in the revolving shaft or journal, such spiral grooves being so arranged as to cross each other. *Patent completed.*

1071. C. Harratt. *Improvements in the manufacture of masts, yards, and booms.* Dated April 14, 1862.

Here is a mast constructed of a series of concentric tubes of sheet metal, the interstices between them being filled up with melted or dissolved india-rubber; or it may be pitch, or other matters which can be made fluid, and will afterwards set solid and yet remain flexible. *Patent abandoned.*

1072. J. Childs. *Improvements in the manufacture of wax matches.* Dated April 14, 1862.

This consists in the use of carnauba wax (a vegetable resin) in the manufacture of wax matches. *Patent abandoned.*

1073. R. A. Brooman. *Improvements in reaping and mowing machines.* (A communication.) Dated April 14, 1862.
